VOLUME XI.

FUEGO, TIERRA DEL——HADDINGTONSHIRE.

LONDON:

CHARLES KNIGHT AND Co., 22, LUDGATE STREET.

MDCCCXXXVIII.

Price Seven Shillings and Sixpence, bound in cloth.

COMMITTEE.

Chairman—The Right Hon. LORD BROUGHAM, F.R.S., Member of the National Institute of France.

Vice-Chairman—JOHN WOOD, Esq.

Treasurer—WILLIAM TOOKE, Esq., F.R.S.

W. Allen, Esq., F.R. and R.A.S.
Captain Beaufort, R.N., F.R. and R.A.S., Hydrographer to the Admiralty.
G. Burrows, M.D.
Peter Stafford Carey, Esq., A.M.
William Coulson, Esq.
R. D. Craig, Esq.
J. F. Davis, Esq., F.R.S.
H. T. Dela Beche, Esq., F.R.S.
The Right Hon. Lord Denman.
Samuel Duckworth, Esq., M.P.
B. F. Duppa, Esq.
The Right Rev. the Bishop of Durham, D.D.
Sir Henry Ellis, Prin. Lib. Brit. Mus.

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

FUE'GO, TIERRA DEL, is the name by which the Archipelago is designated which constitutes the southern extremity of America. It is not known for what reason the Spaniards, who discovered it, gave it the name of Fire-land, but it is supposed that they observed some volcanic eruption on it, though modern navigators have never observed any thing of the kind, except Capt. B. Hall, whose description leaves no doubt that he really saw one.

If we exclude the islands lying along the western coast of South America, north of the Strait of Magalhaens, and consider those only as belonging to this Archipelago which are on the south of it as far as Cape Horn, Tierra del Fuego lies between 52° 30′ and 56° S. lat., and between 65° and 76° W. long. Staten Land however extends more than a degree farther east, but is divided from the Archipelago by the Strait le Maire, which is nearly 20 miles across. The whole length of the Archipelago, from Cape Good Success, on Strait le Maire, to Cape Pillar, at the western entrance of the Strait of Magalhaens, exceeds 400 miles. Its greatest breadth, between 65° and 70° W. long., is not less than 250 miles. In surface perhaps it may be equal to Great Britain, or at least not much less.

Tierra del Fuego consists of one large island, four others of moderate extent, and a great number of smaller islands and rocks. The larger island forms the eastern and northeastern portion of the group, and occupies considerably more than one half of the whole. It is called King Charles's Southland. On the south of it lie the islands of Navarin and Hoste, which are separated from it by Beagle Channel, extending in a straight line, east and west, for 120 miles, and being only from one-third of a mile to one mile across. Navarin island is separated from Hoste island by Ponsonby Sound. To the west of King Charles's Southland are two other large islands, Clarence island and South Desolation. The former is separated from King Charles's Southland by a crooked channel, which towards the Strait of Magalhaens is called Magdalen Sound, but towards the open sea Cockburn Sound. South Desolation, which forms the most western portion of the Archipelago, is separated from Clarence island by Barbara Channel.

The northern portion of King Charles's Southland is a plain, on which there are a great number of low hills, with a gentle ascent. No trees grow upon it, but there are shrubs and grasses. The shrubs are thinly scattered, but the grasses are abundant, and though of a harsh and dry appearance, they feed large flocks of guanacoes. Capt. Fitzroy considers this plain more fertile than those of Patagonia south of 45° S. lat., and thinks that parts of it may be cultivated. It is at present occupied by natives, resembling the Patagonians. [PATAGONIA.] The line of separation between this plain and the mountain-country begins on the Strait of Magalhaens, on the northern shores of Admiralty Sound, and extends thence to Cape Good Success. It is formed by mountains, which perhaps constitute an uninterrupted range, and some of which rise to an elevation of 4000 feet.

The mountainous portion of the Archipelago comprehends the southern and western part of King Charles's Southland, and all the other islands besides. It presents a succession of hills and mountains, valleys and ravines; the mountains rise in general to 2000 or 3000 feet, and several attain the snow-line, being more than 3500 feet in elevation. Mount Sarmiento, on Magdalen Sound, is 6000 feet high. The shores are intersected by deep but narrow arms of the sea, on whose sides rise the mountains, whose summits for the greatest part of the year are covered with snow, while their steep and rocky declivities are partially overgrown with evergreens. The natives of this country differ considerably from the Patagonians: they are low in stature, varying from 4 ft. 10 in. to 5 ft. 6 in. in height, and live in a very barbarous condition; they have frequently no other covering than a scrap of hide, which is tied to their waists. Their colour is darker than that of copper, and like mahogany or rusty iron.

The climate of this Archipelago is considered as extremely cold, and doubtless it is much colder than that of North Britain, which is situated at the same distance from the pole. The difference is perhaps best indicated by the different elevations at which the snow-line occurs. In North Britain it is supposed to be at an elevation of 5000 feet; but in Tierra del Fuego it occurs between 3000 and 3500 feet. The climate of Bergen, in Norway, is perhaps very similar to that of Tierra del Fuego, where, as at Bergen, cloudy weather, rain, and wind prevail throughout the year, and fine days are rare. No season is quite free from frost; the thermometer, even in February, which corresponds to our August, descends occasionally some degrees below the freezing point; but even during the winter, the mean temperature is, according to the observation of Capt. King, 2¼ degrees above that point, though it occasionally descends to 12¼° of Fahrenheit. It seems that this peculiarity of the climate is chiefly to be attributed to the high temperature of the sea, which on its surface is never lower than 45° of Fahrenheit, more especially in the Strait of Magalhaens, where the observations were made at Port Famine. The coasts, which are exposed to the influence of the open ocean, have probably a much colder climate, as during the winter they are surrounded by large fields of ice, which at that season occur as far north as 54° S. lat., along the shores of King Charles's Southland. The level portion of that island suffers rather from want than from abundance of moisture, like the eastern coast of Patagonia. The natural productions of this antarctic region are nearly unknown. Captain King found parrots and humming-birds on the shores of the Strait of Magalhaens. The natives of the mountainous portion live on fish, which seem to abound in the inlets. The extensive forests do not appear to contain trees fit for timber. Guanacoes feed on the extensive and

dry plains of King Charles's Southland, as already observed. (Captain Philip Parker King, in *London Geogr. Journal*, vol. i.; Captain Fitzroy, in ditto, vol. vi.; and Captain Basil Hall's *Journal.*)

FUEL is any combustible matter employed for the purpose of creating and maintaining heat. In the early ages of the world, wood must have constituted, as indeed in many countries it does to this day, the principal fuel employed. Wood consists chiefly of three principles: carbon, hydrogen, and oxygen. The two former are both of them highly combustible; and the last principle is especially so, and is the principal cause of the flame with which wood is well known to burn. When the smoke occasioned by the combustion of wood is found inconvenient, or when the fuel is required to last for a longer period in a given bulk, then charcoal is employed, which is merely wood that has undergone imperfect combustion, so as to expel its hydrogen and oxygen, and to leave the greater part of the carbon.

Another kind of fuel, which doubtless was early in use on account of the facility with which it is obtained from its nearness to the surface, is *peat*, or, as it is sometimes called, *turf:* this is a congeries of vegetable matter, in which the remains of organization are more or less visible. Peat is the common fuel of a large part of Wales and Scotland, and of many districts of England, where coal is not readily procured.

In this country, however, coal furnishes the great supply of fuel, and its various kinds are employed in different ways and for different purposes according to its nature and that of the substance to be acted on by its agency. When coal, by a process analogous to that by which charcoal is procured from wood, is freed from its more volatile constituents, hydrogen, oxygen, and azote, it is converted into coke; it then burns with but little flame and comparatively little smoke, and is used for giving an intense degree of heat in the reduction of most metallic ores, especially those of iron.

In some cases a mixture of coke and charcoal is very advantageously employed, especially in assaying in the small way. The mixture gives out a great degree of heat while burning, and being more combustible than coke alone, small furnaces, in which the draught is less powerful than in larger ones, are particularly adapted for its use: and though it consumes faster than coke, it lasts longer, gives a greater heat, and is more economical than charcoal alone.

In some countries, even the dried excrement of animals is used as fuel: and from the use of camel's dung the formation of sal ammoniac was derived in Egypt; this salt subliming from the excrement during its combustion.

In small chemical operations, as for the blow-pipe, tallow or wax candles are frequently employed; and in lamps, oil, spirit of wine, or pyroxilic spirit, and even carburetted hydrogen gas, are used, either for the purpose of boiling or evaporating small quantities of fluids, or dissolving various bodies in different menstrua.

During the combustion of different kinds of fuel, the products vary: thus, when wood, coal, wax, tallow, oil, alcohol, or carburetted hydrogen is employed, the principal products are carbonic acid gas and water; when charcoal is used, carbonic acid is almost the only volatile substance formed, for the hydrogen which the wood contained is expelled by the process of charring.

FUENTE RABIA, or **FONTARABIA**. [GUIPUZCOA.]

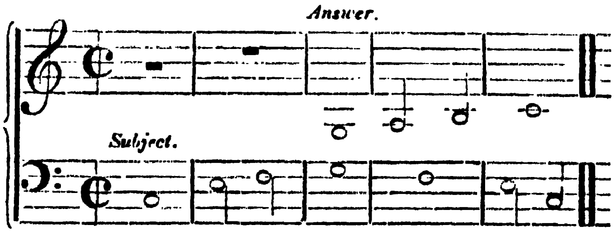
FUERTAVENTURA. [CANARIES.]

FUGGER, a German family, originally of Augsburg, that amassed great wealth in the fifteenth and sixteenth centuries by commerce, and especially by the monopoly of the spices, which they drew from Venice, and with which they supplied Germany and other parts of the Continent. The Fuggers were created counts by Charles V. in 1530, to whom they had lent large sums of money; and a story is told of their lighting a fire of cinnamon-wood with his bond or bonds for the amount, in the presence of Charles, who happened to be a visiter at their house in passing through Augsburg. They also supplied Philip II. with money, and two of their family contracted with the Spanish government for the mines of Almaden. [ALMADEN.] The family became divided into several branches, one of which obtained the rank of princes of the German empire, under the title of Fugger Babenhausen, near Ulm. The family continue to this day, and their domains are partly in Bavaria and partly in Würtemberg. The Fugger family, in the sixteenth century, made a liberal use of their wealth, in founding charitable institutions, such as the one still called Fuggerei [AUGSBURG]; in promoting learning, collecting MSS., and forming valuable libraries. Several members of the family were themselves men of learning; among others Ulrich Fugger, born about 1520, was for a time a confidential attendant of Pope Paul III., but afterwards returned to Germany, and had several valuable MSS. of classic authors which he had collected printed at his own expense. He engaged as his printer Henri Estienne, with a handsome salary. His family being dissatisfied with his expenditure, obtained an order from the civil courts taking away from Ulrich the administration of his property under the pretence of incapacity; but the order was ultimately rescinded, and he was restored to his rights. He died in 1584 at Heidelberg, leaving his fine library to the Elector Palatine and several legacies to poor students. Another Fugger wrote a history of Austria, published at Nürnberg in 1668. Philip Edward Fugger, born in 1546, added greatly to the library and cabinet of antiquities begun by his ancestors at Augsburg, and distinguished himself by his munificence. Otho Henry Fugger, count of Kirchberg and Weissenhorn, born in 1592, served with the Spanish army in Italy, and afterwards raised troops in Germany for the Emperor Ferdinand II. during the Thirty Years' War. (Imhoff, *Notitia Imperii;* Moreri's *Dictionary*, art. 'Fugger;' *Almanach de Gotha.*)

FUGUE, in music, a composition in which a Subject, or brief air, passes successively and alternately from one part to another, according to certain rules of harmony and modulation. Such is Rousseau's definition, which would have been more complete if he had added that the Fugue is also formed after rules peculiar to itself. The term seems to have originated about the middle of the fifteenth century, and is commonly supposed to be derived from the Latin word *fuga* (flight), because the theme, or point, flies from part to part; but this etymology is by no means satisfactory, though we certainly have no better to offer

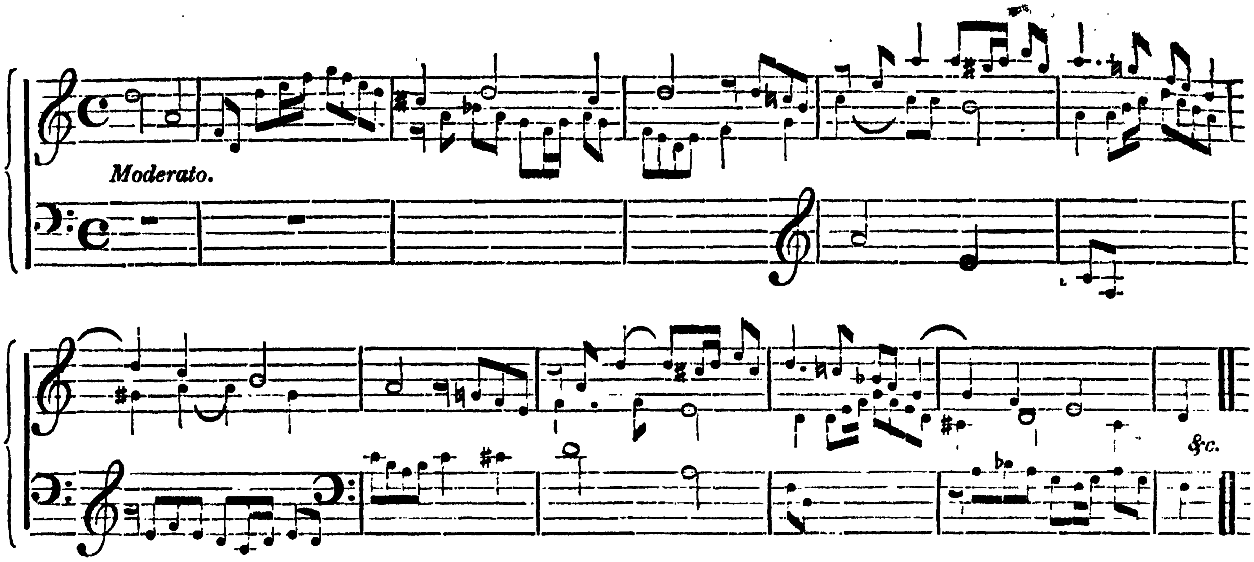
Writers on music enumerate many kinds of Fugue, the chief of which are, the Strict Fugue, the Free Fugue, the Double Fugue, and the Inverted Fugue; to which we shall add that species—for it decidedly belongs to the Fugue genus called Imitation.

'In a Strict Fugue,' says Dr. Crotch (*Elements of Composition*), 'the subject is given out by one of the parts, then the answer is made by another; and afterwards the subject is repeated by a third part, and, if the fugue consist of four parts, the answer is again made by the fourth part: after which the composer may use either the subject or the answer, or small portions of them, in any key he pleases, or even on different notes of the key.' In this severe kind of composition, when the subject, or leader, or point, or *dux*, or by whatever name the theme may be designated, is comprised between the tonic and the dominant, the answer (or *Comes*) must be given in the notes contained between the dominant and the octave. Ex.:



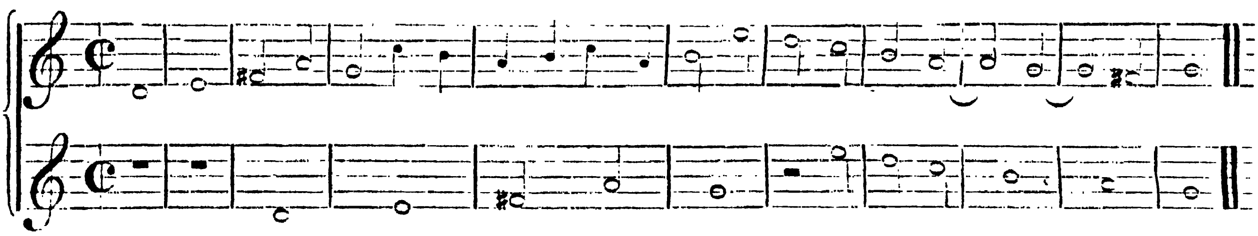
The chorus 'He trusted in God,' in the *Messiah*, is a fine specimen of this sort of fugue, to which we refer the reader; for few are without that sublime oratorio in some form.

In the Free Fugue much more latitude is allowed the composer; he is not so restrained by the subject, but may introduce what Albrechtsberger terms episodes—passages not closely related to the theme, though they should never be very foreign to it. The overture to the *Zauberflöte* affords a splendid example of this species. The Double Fugue consists of two or more subjects, moving together, and dispersed among the different parts. Dom. Scarlatti's in D minor is a double fugue which has no superior of its kind. The first few bars of this will more clearly explain than words can do the nature of so elaborate a species of composition.



Fugues of more than two subjects are classed, not very correctly, among double fugues; they are however rare, for which reason perhaps they have never received a distinguishing name. Of these the fugue of four subjects in the finale to Mozart's grand symphony in C, and that of the same description in Handel's *Alexander's Feast*, the chorus 'Let Old Timotheus yield the prize,' are master-pieces of their kind. All of this species must be considered as free fugues. The term Fugue by Inversion requires little explanation. In this the theme is inverted, as the name implies, but the effect arising out of such contrivance is appreciable only by those who know its difficulty, and estimate its merit by the quantity of labour it has cost. In the Fugue by Augmentation, the notes of the answer are doubled in length. In the Fugue by Diminution, exactly the reverse takes place. There are also other kinds of Fugue, but they are now almost forgotten, and it would be waste of paper and print to revive their names.

Imitation is a species of fugue, and by theorists is generally treated on previously to and as the precursor of the latter. As the word indicates in this kind of composition, the theme is more or less imitated in the different parts. It is not, says Fux (*Gradus ad Parnassum*), required that every note should be imitated, but only some part of the subject: and Imitation is rather to take place in the middle than in the commencement of a composition. It may be made in any of the intervals, and in fact is governed by scarcely any rule. The learned contrapuntist just named gives the following as an example of Imitation in the Unison:—



The effect of technical imitation in music is unquestionably great: it is felt by all who have the slightest skill in the art, therefore employed by all great composers of every school, antient and modern. Canon, which is sometimes called a perpetual fugue, may perhaps be admitted, though cautiously, as part of a course of professional study, but should rarely, if ever, be allowed to pass the boundaries of the school. [CANON.] Fugue, but not of the pedantic or fantastic kind, should be an object of serious attention with those who are ambitious of becoming great composers, though in its severe form it ought to be almost confined to cathedral music and to the oratorio, and is admissible there only when introduced with great discretion, and guided by the hand of an experienced sensible master. But without that which is here to be understood by the term imitation—or the recurrence, in some shape, of the chief subject—music in parts, of even a very simple kind, loses one of its greatest beauties. Let it be used however with a view solely to effect: if resorted to for the mistaken purpose of displaying what a young or a dull composer may call his learning, imitation will prove to be nothing better than mere plodding, and capable of exciting no emotion except that which is the very reverse of pleasing.

FULCRUM. [LEVER.]

FULDA, river. [WESER.]

FULDA, a province of the electorate of Hesse-Cassel, between 50° and 51° N. lat., and 9° and 10° E. long., is bounded on the north-east by Saxe-Weimar, on the east and south-east by Bavaria, and on the west by the grand-duchy of Hesse-Darmstadt. Its area is about 880 square miles, and its population about 126,600. It contains part of the former grand duchy of Fulda (a considerable portion of it having been united to Bavaria in 1815), the principality of Hersfeld, and the seigniory of Schmalkalden. The former territory of Fulda was one of the oldest ecclesiastical endowments in Germany, having been founded by Bonifacius and his colleague Sturm, in the year 744: it ceased however to be under episcopal jurisdiction in 751, was revived as a bishoprick in 1752, fell to the prince of Nassau-Orange as a secularized principality in 1803, was incorporated by Napoleon with the grand-duchy of Frankfort in 1810, and in 1815, after being ceded to Prussia, was immediately afterwards made over to Hesse-Cassel. The soil is not so rich as that of other parts of the electorate; the country is intersected by branches of the Rhön and Vogel ranges, and watered by the Fulda, Kinzig, Werra, Haune, and other rivers. It produces corn, flax, potatoes, and timber, in considerable quantities. The rearing of cattle is one of the principal occupations of the inhabitants: among the mineral productions are brown coal, potter's clay, and small quantities of salt.

The province is divided into the circles of Hersfeld, Schmalkalden, Hünfeld, and Fulda, and contains five towns, seven market villages, and 198 other villages, together with about 17,200 houses. Besides Fulda, the chief town, the principal towns are Hersfeld, on the Fulda, and Geiss, a walled town, with a spacious market place, a castle, 2 churches, about 670 houses and 6400 inhabitants, and manufactures of woollens, dimity, serges, and leather. Schmalkalden, on the Schmalkalde, surrounded by walls, with 3 suburbs, the 2 castles of Wilhelmsburg and Hessenhof, 2 churches, 2 gymnasia, and salt-works producing annually about 620 tons. The population is about 4850. Large quantities of iron and steel ware are made here, besides salt, stockings, white lead, arms, buttons, pipeheads of Meerschaum, woollen yarn, &c. This was the place where the Protestant princes of Germany formed a league for their mutual defence in 1531, after six great assemblies held here

between 1529 and 1540. The Schmalkald articles were also promulgated from this spot in 1537. Steinbach, a market village on the Hasel, with about 390 houses, and 2500 inhabitants, who manufacture iron-ware. Hünfeld on the Haune, a town with walls, 2 churches, about 280 houses, and 1800 inhabitants, with manufactures of linens, and some trade in yarns: and Brotterode, an irregularly built town, 1708 feet above the level of the sea, with about 350 houses, and 2100 inhabitants, and manufactures of tin, tobacco, brass and steel ware, &c.

FULDA, the capital of the province, and the seat of its government and law courts, is about 60 miles north-east of Frankfort on the Main, at an elevation of 834 feet above the level of the sea; in 50° 34′ N. lat., and 9° 44′ E. long. It is built on the banks of the Fulda, which is crossed by a handsome stone bridge. Fulda is a pretty town, with eight suburbs outside its walls. The walls, which are decayed, have seven gates. Its population, which was 7468 in 1810, and 8150 in 1817, is at present about 9600; the houses are about 1100. It contains a market-place and two squares, one of which is a public promenade, with rows of linden trees, an electoral palace and grounds, eleven churches, one of which is Lutheran, a Roman Catholic Lyceum, which was instituted out of the funds of the university, founded in 1734, a Protestant high-school, a chapter seminary, a school in which forest economy is taught, and another for educating teachers, an hospital, public library, &c. It is the residence of the Roman Catholic bishop for the electorate, and has a handsome cathedral or minster, built between the years 1700 and 1712: it is memorable as the place of sepulture of St. Bonifacius, whose remains were deposited below an altar in an underground chapel in 755, the year of his death. The manufactures of Fulda are on a confined scale, and consist of linens, woollens, stockings, saltpetre, leather, articles in wood, &c. The mineral spring, on St. John's Hill near the town, resembles the Seltzer water. About five miles out of Fulda is the electoral country-seat called the Fasanerie, where there are valuable collections of paintings, china, and subjects in natural history. St. Bonifacius's Well, in the midst of some well laid out shrubberies, is also close to the town.

FULGE'NTIUS, FABIUS CLAUDIUS GORDIANUS, bishop of Ruspina, a town on the coast of Africa, was born about A.D. 464. His father Gordianus, who was a senator of Carthage, was obliged to leave his native city during the persecutions of the Vandals, and retired to Telepte, in the province of Byzacium, where Fulgentius passed the early years of his life. He is said to have made great progress in his studies, and to have acquired an accurate knowledge of the Greek and Latin languages. In consequence of his attainments, he was appointed at an early age to receive the public revenues of the province; but he resigned his office soon after his appointment, and retired to a monastery in the neighbourhood. After enduring many persecutions on account of his opposition to the Arian doctrines, he resolved to go into Egypt to visit the celebrated monks of that country. From this design he was dissuaded by Eualius, bishop of Syracuse, on the ground that the monks of the East had withdrawn from the Catholic communion, and accordingly he proceeded to Rome, A.D. 500. On his return to his native country, the Catholic clergy elected him bishop of Ruspina; but he did not enjoy his dignity long, being exiled to Sardinia, together with the other Catholic bishops of that part of Africa, by Thrasimond, king of the Vandals. His learning, his austere manner of living, and his frequent controversies with the Arians, procured him the universal respect of the Catholic clergy, who considered him the greatest ornament of the African church in that age. Curiosity led Thrasimond to recal him to Carthage, where he held disputes with the king on the debated points of the Arian controversy; but as he was unable to convince the monarch, he was obliged to return to Sardinia, where he remained till A.D. 522, when the death of Thrasimond and the succession of Hildericus to the throne occasioned the recal of the Catholic bishops. Fulgentius returned to Ruspina, and resided there till the time of his death, which happened either in A.D. 529 or 536.

His works were printed at Paris, in a 4to. volume, in 1684. With regard to his style, Dupin remarks, 'that St. Fulgentius did not only follow the doctrine of St. Austin, but also imitated his style. He had a quick and subtle spirit, which easily comprehended things, set them in a good light, and explained them copiously, which may appear unpleasant to those who read his works. He loved thorny and scholastic questions, and used them sometimes in mysteries. He knew well the holy Scriptures, and had read much the works of the fathers, particularly those of St. Austin.' His principal works are:—I. 'Three Books to Thrasimond, king of the Vandals, on the Arian Controversy;' II. 'Three Books to Monimus.' The first supports the opinions of Augustine on the doctrine of predestination; the second explains the sacrifice of Christ and the passage in 1 Cor. vi., 6, 'But I speak this by permission, and not of commandment;' the third contains remarks on the Arian interpretation of John i., 1, 'The word was with God.' III. 'Two Books to Euthymius, on the Remission of Sins,' to show that God will pardon sins only in this life; IV. 'A Book to Donatus, on the Trinity;' V. 'Three Books on Predestination, to John, a priest, and Venerius, a deacon;' VI. 'A Book on Faith;' VII. 'Letters on various religious Subjects,' written principally during his exile.

(Dupin's *Bibliothèque Ecclésiastique*, vol. v., p. 13-21; Eng. Trans.; *Acta Sanctorum*, vol. i., Januar., p. 32.)

FULGENTIUS FERRANDUS, who is frequently confounded with Fulgentius, bishop of Ruspina, lived in the beginning of the sixth century. He was a disciple of the bishop of Ruspina, whose life he wrote. He was also the author of an 'Abridgment of the Canons,' and finished a treatise addressed to Reginus, on which his master was engaged at the time of his death.

(Mosheim's *Ecclesiastical History*, vol. ii., p. 109: Eng. Trans., 1826.)

FULGENTIUS, FABIUS PLANCIADES, is said to have been a bishop of Carthage, and to have lived in the sixth century. He wrote a work on Mythology, in three books, addressed to a priest of the name of Catus, which was printed for the first time at Milan, in 1487. There is another work of Fulgentius, entitled 'Expositio Sermonum Antiquorum ad Chalcidicum Grammaticum,' which is usually printed with the works of Nonius Marcellus

(Fabricii, *Bibliotheca Latina*, lib. ii., c. 2.)

FULGURITES are vitrified sand tubes, supposed to have originated from the action of lightning; they are called by the Germans *blitzröhre*.

These tubes were discovered in the year 1711 by the pastor Herman, at Massel in Silesia; and they were again discovered in 1805 by Dr. Hentzen, in the heath of Paderborn, commonly called the Senne, and he first attributed their formation to the agency of lightning.

These tubes have since been found in great number at Pillau, near Königsberg, in Eastern Prussia; at Nietleben, near Halle on the Saale; at Drigg in Cumberland, and some other places.

At Drigg, the tubes were found in the middle of sandbanks forty feet high, and very near the sea. In the Senne they were most commonly found on the declivities of mounds of sand, about thirty feet high; but sometimes in cavities, which are stated to have been hollowed in the heath, in the form of bowls, 200 feet in circumference, and 12 to 15 feet in depth.

These tubes are nearly all hollow. At Drigg their external diameter was 2½ inches; those of the Senne, reckoning from the surface, are from one quarter to seven lines internal diameter; but they narrow as they descend lower, and frequently terminate in a point: the thickness of the tube varies from half a line to one inch.

These tubes are usually placed vertically in the sand; but they have been found at an angle of 40°. Their entire length, judging from those which have been extracted, is from twenty to thirty feet; but frequent tranverse fissures divide them into portions from half an inch to five inches in length.

Usually there is only one tube found at a place; sometimes however, at a certain depth, this tube divides into two or three branches, each of which gives rise to small lateral branches, from an inch to a foot in length; these are conical, and terminate in points, inclining gradually to the bottom.

The internal part of the tubes is a perfect glass, smooth and very brilliant, resembling hyalite. It scratches glass, and gives fire with steel. All the tubes, whatever may be their form, are surrounded by a crust composed of agglutinated grains of quartz, which have the appearance, when examined by a glass, of having undergone incipient fusion.

The colour of the internal mass of the tubes, and especially that of the external parts, depends upon the na-

ture of the sandy strata which they traverse. In the superior beds, which contain a little soil, the exterior of the tubes is frequently black; lower down the colour of the tube is of a yellowish grey; still lower, of a greyish white; and lastly, where the sand is pure and white, the tubes are almost perfectly colourless.

That the cause of these tubes is correctly attributed to lightning is shown by some observations presented to the Royal Society, in 1790, by Dr. Withering. On opening the ground where a man had been killed by lightning, the soil appeared to be blackened to the depth of about ten inches; at this depth, a root of a tree presented itself, which was quite black; but this blackness was only superficial, and did not extend far along it. About two inches deeper, the melted quartzose matter began to appear, and continued in a sloping direction to the depth of eighteen inches; within the hollow part of one mass, the fusion was so perfect, that the melted quartz ran down the hollow, and assumed nearly a globular figure.

Professor Hagen, of Königsberg, has made a similar observation. In the year 1823 the lightning struck a birch tree at the village of Rauschen; on cautiously removing the earth, Professor Hagen found, at the depth of a foot, the commencement of a vitrified tube, but it could not be extracted from the sand in pieces of more than two or three inches in length; the interior of these fragments was vitrified, as usual; several were flattened, and had zigzag projections.

It is also to be observed, that Saussure found on the slaty hornblende of Mont Blanc small blackish beads, evidently vitreous, and of the size of a hemp-seed, which were clearly the effects of lightning. Mr. Ramond has also remarked on the Pic du Midi, in the Pyrenees, some rocks, the entire face of which is varnished with a coating of enamel, and covered with beads of the size of a pea; the interior of the rock is totally unchanged.

FULHAM. [MIDDLESEX.]

FULICA. [RALLIDÆ.]

FULIGULINÆ, a subfamily of the *Anatidæ*. The prince of Musignano (C. L. Bonaparte) arranged, under the subgenus *Fuligula*, those species of ducks which other modern ornithologists have distinguished by the generic titles of *Somateria*, *Oidemia*, *Fuligula*, *Clangula*, and *Harelda*. The prince observes, that M. Temminck, who had been opposed to all dismemberment of the great genus *Anas*, had at last been induced to assemble all the species of the prince's subgenus *Fuligula* under one genus; whence the prince argues the necessity of M. Temminck's admitting the *swans* and *geese* as distinct genera; and he observes that he cannot see any good reason why M. Temminck should have rejected the name of *Fuligula*, as well as *Platypus*, given anteriorly to the genus by Brehm, and should have imposed on it the name of *Hydrobates*, a term already applied by Vieillot to the genus *Cinclus*. (*Specchio Comparativo*.)

Mr. Swainson (*Fauna Boreali-Americana*) adopts the term *Fuligulinæ* to distinguish this subfamily, under which he arranges the genera *Somateria*, *Oidemia*, *Fuligula*, *Clangula*, and *Harelda*.

Habits, Food, &c.—The *Fuligulinæ*, or *sea ducks*, as they have been not inaptly named, frequent the sea principally; but many of them are to be found in the fresh-water lakes and rivers where the water is deep. The plumage is very close and thick in comparison with that of the true ducks (*Anatinæ*), and the covering of the female differs much in hue from that of the male, which when adult undergoes but little change in its dress from the difference of season. The young resemble the female in their feathered garb, and do not assume the adult plumage till the second or third year. Moulting takes place twice a year without change of colour. In the male, the capsule of the trachea is large.

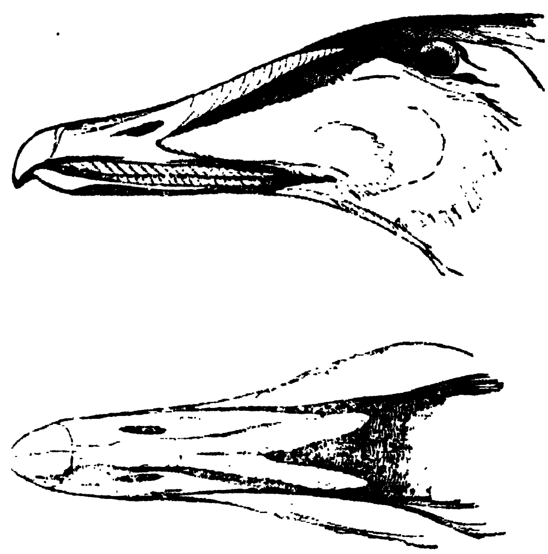
The *Sea Ducks* are not good walkers, on account of the backward position of their feet, but they run, or rather shuffle along rapidly, though awkwardly. They swim remarkably well, though low in the water, and excel in diving, whether for amusement, safety, or food, which last consists of insects, mollusks, the fry of fish, and marine or other aquatic vegetables. They take wing unwillingly as a security from danger, relying more confidently on their powers of diving and swimming as the means of escape, than on those of flight. Though they are often strong, steady, rapid, and enduring in their passage through the air, they generally fly low, laboriously, and with a whistling sound.

This subfamily may be considered to be monogamous, and the nest is frequently made near the fresh waters; the female alone incubating, though both parents, in several of the species at least, strip the down from their breasts as a covering for the eggs, which are numerous.

Geographical Distribution.—The North may be considered the great hive of the *Fuligulinæ*; though some of the forms are spread over the greater part of the globe. Large flocks are seen to migrate periodically, keeping for the most part the line of the sea-coast, and flying and feeding generally by night, though often, especially in hazy or blowing weather, by day.

SOMATERIA. (Leach.)

Generic Character.—*Bill* small, with the base elevated and extending up the forehead, where a central pointed line of feathers divides it; the anterior extremity narrow but blunt; *nostrils*, mesial; *neck*, thick; *wings*, short; *tertiaries* long, and generally with an outward curve, so as to overlie the *primaries*. Tail moderate, consisting of 14 feathers.



Bill of Eider Duck.

This genus is peculiarly marine. Dr. Richardson, whose opportunities of observing the northern birds were so great, and so well used, says, that *Somateriæ spectabilis* and *mollissima* are never, as he believes, seen in fresh water; their food consisting mostly of the soft mollusca in the Arctic Sea. They are, he says, only partially migratory, the olde birds seldom moving farther southwards in winter than to permanent open water. He states that some *eider ducks* pass that season on the coast of New Jersey, but that the *king ducks* (*S. spectabilis*) have not been seen to the southward of the 59th parallel. Audubon however says, that in the depth of winter the latter have been observed off the coast of Halifax, in Nova Scotia, and Newfoundland, and that a few have been obtained off Boston, and at Eastport in Maine.

The genus is remarkable for the high development of the exquisitely soft and elastic down so valuable in commerce, and so essential to the keeping up of the proper balance of animal heat in the icy regions inhabited by these birds. We select as our example:—

Somateria mollissima (*Anas mollissima*, Linn.), the *Eider Duck*. This is the *Oie à duvet ou Eider* of the French; *Die Eidergans* and *Eiterente* of the Germans; *Oca Settentrionale* of the Italians (*Stor. degli ucc.*); the *Eider Goose*, *Eider Duck*, *St. Cuthbert's Duck*, *Cuthbert-Duck*, or *Cutbert-Duck*, *Great black and white-Duck*, and *Colk Winter Duck*, of the modern British; *Hwyad fwythblu*, of the ancient British; *Dunter Duck*, of the Hudson's Bay residents; and *Mittek*, of the Esquimaux.

The following is Dr. Richardson's description of a *male* killed June, 14, 1822, at Winter Island, 66° 11½′ N. lat. *Colour*. Circumference of the frontal plates, forehead, crown, and under eye-lid, deep Scotch blue; hind head, nape and temples, siskin-green. Stripe on the top of the head, cheeks, chin, neck, breast, back, scapulars, lesser coverts, curved tertiaries, sides of the rump, and under wing-coverts, white; the tertiaries tinged with greenish yellow, and the breast with buff. Greater coverts, quills, rump, tail and its co-

verts, and the *under plumage*, pitch black; the end of the quills and tail fading to brown. *Bill*, oil-green. *Legs*, greenish yellow.

Form. *Bill* prolonged on the lengthened, depressed forehead, into two narrow flat plates that are separated by an angular projection of the frontal plumage. *Nostrils* not pervious. *Neck*, short and thick. *Wings* nearly three inches shorter than the tail. Hind toe attenuated posteriorly into a broad lobe. The length of this bird was 25 inches 6 lines.

Female. Pale rufous or yellowish brown with black bars; *wing-coverts* black, with ferruginous edges; *greater coverts* and *secondaries* with narrow white tips; head and upper part of the neck striped with dusky lines. *Beneath*, brown with obscure darker blotches.

Young at the age of a week. Of a dark mouse colour, thickly covered with soft warm down.

Young male. Like the female; and not appearing in the full adult male plumage till the fourth year.

Geographical Distribution.—The icy seas of the North appear to be the principal localities of this species. Captain, now Major Edward Sabine, enumerates it among the animals which were met with during the period in which the expedition under Captain Parry remained within the Arctic circle. He mentions it as abundant on the shores of Davis' Straits and Baffin's Bay: but adds, that deriving its food principally from the sea, it was not met with after the entrance of the ships into the Polar Ocean, where so little open water is found. The females were without the bands on the wings described by authors. (Appendix to Captain Sir W. E. Parry's First Voyage, 1819—20.) The late lamented Captain Lyon saw the Eider in Duke of York's Bay. (*Journal*.) Captain James Ross (Appendix to Captain Sir John Ross's Last Voyage), notices vast numbers of the *king duck* as resorting annually to the shores and islands of the Arctic regions in the breeding season, and as having on many occasions afforded a valuable and salutary supply of fresh provision to the crews of the vessels employed in those seas. Speaking of the *eider duck* he says, it is so similar in its habits to the *king duck*, that the same remarks apply equally to both. In Lapland, Norway, Iceland, Greenland, and at Spitzbergen, the eider duck is very abundant; and it abounds also at Bering's Island, the Kuriles, the Hebrides, and Orkneys. In Sweden and Denmark it is said to be more rare, and in Germany to be only observed as a passenger. Temminck states that the young only are seen on the coasts of the ocean, and that the old ones never show themselves. Captain James Ross, in the Appendix above alluded to, speaking of the eider down, says that the down of the *king duck* is equally excellent, and is collected in great quantities by the inhabitants of the Danish colonies in Greenland, forming a valuable source of revenue to Denmark. A vast quantity of this down, he adds, is also collected on the coast of Norway, and in some parts of Sweden. The eider duck is found throughout Arctic America, and is said to wander, in severe winters, as far south to sea as the capes of the Delaware. From November to the middle of February, small numbers of old birds are usually seen towards the extremities of Massachusetts Bay, and along the coast of Maine. A few pairs have been known to breed on some rocky islands beyond Portland, and M. Audubon found several nesting on the island of Grand Manan in the Bay of Fundy. The Prince of Musignano notes it as rare and adventitious in the winter at Philadelphia. The most southern breeding place in Europe is said to be the Fern or Farn Isles, on the coast of Northumberland.

Habits, Reproduction, &c.—Willughby, quoting Wormius, says that the Eider Ducks 'build themselves nests on the rocks, and lay good store of very savoury and well-tasted eggs; for the getting of which the neighbouring people let themselves down by ropes dangerously enough, and with the same labour gather the feathers (*Eider dun* our people call them), which are very soft and fit to stuff beds and quilts; for in a small quantity they dilate themselves much (being very springy) and warm the body above any others. These birds are wont at set times to moult their feathers, enriching the fowlers with this desirable merchandize.' Willughby also remarks that 'when its young ones are hatched it takes them to the sea and never looks at land till next breeding time, nor is seen anywhere about our coasts.' This early account is in the main correct; but there are two kinds of Eider down: the *live down*, as it is termed, and the *dead down*; the latter, which is considered to be very inferior in quality, is that taken from the dead bird. The down of superior quality, or live down, is that which the duck strips from herself to cherish her eggs. Its lightness and elasticity are such, it is asserted, that two or three pounds of it squeezed into a ball which may be held in the hand will swell out to such an extent as to fill a case large enough for the foot covering of a bed. It is collected in the following manner: The female is suffered to lay her five or six eggs, which are about three inches in length and two in breadth. These, which are very palatable, are taken, and she strips herself a second time to supply the subsequent eggs. If this second batch be abstracted, the female being unable to supply any more down, the male plucks his breast, and his contribution is known by its pale colour. The last deposit, which rarely consists of more than two or three eggs, is always left; for if deprived of this their last hope, the bereaved birds forsake the inhospitable place; whereas, if suffered to rear their young, the parents return the following year with their progeny. The quantity of down afforded by one female during the whole period of laying is stated at half a pound neat, the quantity weighing nearly a pound before it is cleansed. Of this down Troil states that the Iceland company sold in one year (1750) as much as brought 850*l*. sterling, besides what was sent to Glückstadt.

The haunts of birds capable of producing so valuable an article are not unlikely to be objects of peculiar care: we accordingly find that in Iceland and Norway the districts resorted to by them are reckoned valuable property, and are strictly preserved. Every one is anxious to induce the Eiders to take up their position on his own estate: and when they show a disposition to settle on any islet, the proprietor has been known to remove the cattle and dogs to the mainland in order to make way for a more valuable stock, which might be otherwise disturbed. In some cases, artificial islets have been made by separating promontories from the continent; and these Eider tenements are handed down from father to son like any other inheritance. Notwithstanding all this care to keep the birds undisturbed, they are not, as we shall presently see, scared by the vicinity of man, in some places at least. We proceed to give the personal observations of some of those who have visited Eider settlements:—'When I visited the Farn Isles,' writes Pennant (it was on the 15th July, 1769), 'I found the ducks sitting, and took some of the nests, the base of which was formed of sea-plants, and covered with the down. After separating it carefully from the plants, it weighed only three-quarters of an ounce, yet was so elastic as to fill a larger space than the crown of the greatest hat. These birds are not numerous on the isles; and it was observed that the drakes kept on those most remote from the sitting-places. The ducks continue on their nests till you come almost close to them, and when they rise are very slow fliers. The number of eggs in each nest was from three to five, warmly bedded in the down, of a pale olive colour, and very large, glossy and smooth.' Horrebow declares that one may walk among these birds while they are sitting without scaring them; and Sir George Mackenzie, during his travels in Iceland, had an opportunity, on the 8th June at Vidöe, of observing the Eider ducks, at all other times of the year perfectly wild, assembled for the great work of incubation. The boat, in its approach to the shore, passed multitudes of these birds, which hardly moved out of the way; and, between the landing-place and the governor's house, it required some caution to avoid treading on the nests, while the drakes were walking about, even more familiar than common ducks, and uttering a sound which was like the cooing of doves. The ducks were sitting on their nests all round the house, on the garden wall, on the roofs, nay even in the inside of the houses and in the chapel. Those which had not been long on the nest generally left it when they were approached; but those that had more than one or two eggs sat perfectly quiet and suffered the party to touch them, though they sometimes gently repelled the intrusive hand with their bills. But, if a drake happen to be near his mate when thus visited, he becomes extremely agitated. He passes to and fro between her and the suspicious object, raising his head and cooing.

M. Audubon saw them in great numbers on the coast of Labrador—where, by the way, the down is neglected*.

* Audubon says that the eggers of Labrador collect it; but, at the same time, make such havoc among the birds, that at no very distant period the traffic must cease.

employed about their nests, which they begin to form about the end of May. They arrive there and on the coasts of Newfoundland about the first of that month. The eggs were of a dull greenish-white, and smooth, from six to ten in number. The nest was usually placed under the shelter of a low prostrate branched and dwarf fir*; and sometimes there were several under the same bush, within a foot or two of each other. The ground-work of the nests consisted of sea-weeds and moss, and the female did not add the down till the eggs were laid. The duck, having at this time acquired an attachment for her eggs, was easily approached, and her flight was even and rather slow. Audubon states that, as soon as incubation has commenced, the males leave the land and join together in large flocks out at sea: they begin to moult in July, and soon become so bare as to be scarcely able to rise from the water. By the 1st of August, according to the same author, scarcely an Eider Duck was to be seen on the coast of Labrador. The young, as soon as hatched, are led by the female to the water, where they remain, except at night and in stormy weather. Their greatest feathered enemy is the Saddle-backed Gull, or Black-backed Gull (*Larus marinus*), which devours the eggs and young, but whose pursuit the young, after they have left the nest, elude by diving, at which both old and young are very expert.

Eider Duck, male and female.

According to Brunnich and others, the male utters a hoarse and moaning cry at the pairing time, but the cry of the female is like that of the common duck. Both sexes assist in forming the nest, though the female only sits: but the male watches in the vicinity, and gives notice of the danger. This seems to be confirmed by the account given of the nesting-place at Vidöe. Sometimes two females deposit their eggs in the same nest, and sit amicably together. The Gulls are not their only enemies in addition to man, for the Ravens often suck their eggs and kill their young. At sea, several hatches congregate, led by the females, and there they may be seen splashing the water in the shallows, to beat up the small crustaceans and mollusks, and diving in deeper water for the larger marine animals, among which muscles and other conchifers, turbinated testaceans, and occasionally sea-eggs (*Echini*) are said to be taken.

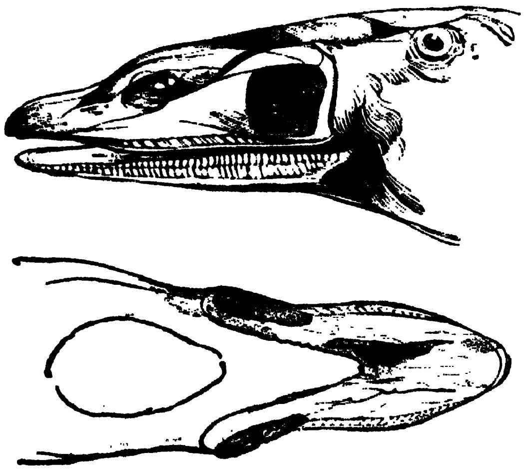
Utility to Man.—The down above described is the principal tribute paid by the Eider Duck to man: but the Indian and Greenlander eat the flesh, which is dark and fishy, and their skin is converted into a warm inner garment. According to Sir W. E. Parry, the Esquimaux Indians catch these birds with springes made of whalebone, and take the eggs wherever they can find them. The skin, prepared with the feathers on, forms an article of commerce, particularly with the Chinese. M. Audubon is of opinion that if this valuable bird were domesticated, it would prove a great acquisition, both on account of its down, and its flesh as an article of food; and he is persuaded that very little attention would effect this. Indeed, it appears that the experiment was made at Eastport with success, but the greater number of the ducks were shot, being taken by gunners for wild birds. The same author says that, when in captivity, it feeds on different kinds of grain and moistened corn-meal, when its flesh becomes excellent. Mr. Selby succeeded twice in rearing Eiders from the egg, and kept them alive upwards of a year, when they were accidentally killed.

Oidemia. (*Fleming.*)

Generic Character.—*Bill*, broad with dilated margins, and coarse lamelliform teeth, gibbous above the *Nostrils*, which are nearly mesial, large and elevated. *Tail*, of fourteen feathers.

The *Oidemiæ* seek their food at sea principally; and have obtained the name of *Surf Ducks*, from frequenting its edge. The prevailing colour of the tribe is black in the male, and brown in the female. The plumage is very thick and close; and, according to Audubon, the down in the *Velvet Duck* (*Oidemia fusca*) is similar to that of the *Eider Duck*, and apparently of equal quality. Their flesh is high-flavoured and oily, according to Dr. Richardson, who gives that character to the flesh of three species, viz. *Oidemiæ perspicillata*, *fusca*, and *nigra*. The two former, according to that enterprising zoologist, breed on the Arctic coasts, migrate southward in company with *Clangula* (*Harelda?*) *glacialis*, halting both on the shores of Hudson's Bay and on the lakes of the interior, as long as they remain open, and then feed on tender shelly mollusca. *Oidemia nigra*, he adds, frequents the shores of Hudson's Bay, and breeds between the 50th and 60th parallels. It was not seen by Dr. Richardson and his companions in the interior. We select, as an example—

Oidemia perspicillata, *Anas perspicillata* of Linnæus, the *Black* or *Surf Duck*. This is the *Macreuse à large bec ou Marchand* and *Canard Marchand* of the French, *the Black Duck* of Pennant, and *the Great Black Duck from Hudson's Bay* of Edwards.



Bill of Oidemia perspicillata.

Description.—*Male*, velvet black, with a reddish reflexion. Throat brownish. A broad white band between the eyes, and a triangular patch of the same on the nape. *Bill* reddish orange, the nail paler; a square black spot on the lateral protuberance. *Legs* orange; webs brown. Bill much like that of the *Velvet Duck* (*Oidemia fusca*), but

* Nuttall suggests that the fir was, probably, *Pinus Banksiana*.

lateral protuberances are naked and horny, and the ...tral one is feathered farther down. The *laminæ* are ...ant, and the lower ones particularly prominent, with ...tting edges. As in the other Oidemiæ, the bill and forehead are inflated, causing the head to appear lengthened and the crown depressed. The *nostrils* are rather large, and nearer to the point than to the rictus. Length 24 inches. (Dr. Richardson, from a bird killed at Fort Franklin.)

Female and Young.—Black ashy brown wherever the male is deep black. *Head* and *neck* lighter; frontal band and great angular space upon the nape indicated by very bright ashy brown. Lateral protuberances of the *bill* but little developed, and the whole bill of an ashy yellowish colour. *Feet* and *toes* brown; *webs* black. (Temminck.) Dr. Richardson observes that the under plumage in particular is paler, that the *back* and *wing coverts* are narrowly edged with grey, that the *breast, flanks*, and *ears* have some whitish edgings, that the *bill* is black, its base not so much inflated, and that the nostrils are smaller than in the male.

Geographical Distribution.—Rare and accidental in the Orcades, and in the higher latitudes towards the pole; very rare in the cold and temperate countries bathed by the ocean; very common and numerous in America, at Hudson's and Baffin's Bays. Such is Temminck's account. Nuttall says that this species of duck, with other dark kinds commonly called on the other side of the Atlantic 'coots,' may be properly considered as an American species; its visits in the Orkneys and European seas being merely accidental. They breed on the Arctic coasts, and extend their residence to the opposite side of the continent, having been seen at Nootka Sound by Captain Cook. The bird is not mentioned in the notice of the animals which were met with during the period in which the expedition remained within the Arctic Circle, appended to Captain Sir W. E. Parry's First Voyage, nor in Captain James Ross's Appendix to Captain Sir John Ross's Last Voyage. The Prince of Musignano notes it as very common, and most abundant in the sea in the neighbourhood of the shore at Philadelphia.

Habits, Reproduction, &c.—In summer the *Surf Duck* feeds principally in the sea, and haunts shallow estuaries, bars and bays, where it may be seen constantly diving for its shelly food. The surf is a favourite station with it. Hudson's Bay and Labrador are among its breeding places, and the nest is formed of grass with a lining of down or feathers on the borders of fresh-water ponds. The eggs are white, and from four to six in number. The young are hatched in July, and detained on the borders of the ponds, where they were excluded from the egg, until they are able to fly. Their migrations extend to Florida, but they often remain throughout the winter along the shores and open bays of the United States. At the end of April or early in May they again proceed northward.

Utility to Man.—The flesh of the old birds is very dark, red, and fishy when dressed; the young are of better flavour. They are however often eaten by the inhabitants of the coasts frequented by them; and being difficult to approach, they are decoyed by means of a wooden figure of a duck of the same general appearance with themselves.

Oidemia perspicillata, Male.

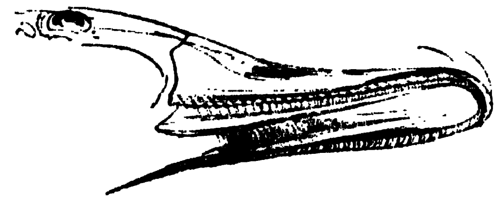
Fuligula. (Ray.)

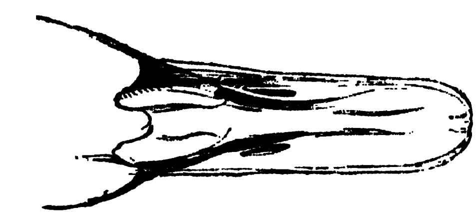
Generic Character.—*Bill* flat, broad, long, with hardly any gibbosity at the base, and rather dilated at the extremity. *Nostrils* suboval, basal. *Tail* short, of 14 feathers, graduated laterally. First *quill* longest.

The sea, and its bays and estuaries, are the principal haunts of this genus. Dr. Richardson states that *Fuligulæ Valisneria, ferina, marila*, and *rufitorques*, breed in all parts of the fur countries, from the 50th parallel to their most northern limits, and associate much on the water with the *Anatinæ*. *Fuligula rubida*, he remarks, frequents the small lakes of the interior up to the 58th parallel, and he adds that it is very unwilling to take wing, and dives remarkably well. In swimming, according to the same observer, it carries its tail erect, and, from the shortness of its neck, nearly as high as its head, which, at a little distance, causes it to appear as if it had two heads. The Canvass-back Duck, *Fuligula Valisneria**, *Anas Valisneria* of Wilson, may be selected as an illustration of the genus.

Description.—The following accurate description of a male, killed on the Saskatchewan on the 3rd of May, 1827, is given by Dr. Richardson in 'Fauna Boreali-Americana.' *Colour.*—Region of the *bill*, top of the head, chin, base of the neck, and adjoining parts of the breast and back, rump, upper and under tail-coverts, pitch-black; sides of the head and the neck reddish-orange; middle of the back, scapulars, wing-coverts, tips of the secondaries, tertiaries, flanks, posterior part of the belly and thighs, greyish-white, finely undulated with hair-brown; primaries and their coverts hair-brown, their tips darkest; secondaries ash-grey, tipped with white; the two adjoining tertiaries edged with black. *Belly* white, faintly undulated on the medial line. In some specimens the white parts are glossed with ferruginous. *Bill* and *legs*, blackish-brown. *Form.*—*Bill* lengthened, the depressed frontal angle longer, the nostrils farther from the front, and the unguis differently shaped and smaller than in *Fuligula ferina* (the Pochard); the *upper laminæ* flat, cuneate, not prominent, and confined within the margin of the mandible. The bill and head of the Canvass-back approach somewhat to the form of the *Pintail Duck*, being much lengthened, and of equal breadth throughout. *First quill* the longest. Length, 24 inches 6 lines.

Female.—Ground colour of the upper plumage and flanks liver-brown: sides of the head, neck, and breast, ferruginous; shoulders, shorter scapulars, and under plumage edged with the same. Middle of the back and wing-covert clove-brown, finely undulated with greyish white. There are no undulated markings on the tertiaries and secondaries, and only a few on the tips of the scapulars. *Bill* as in the male: the neck more slender. (Dr. Richardson.)





Bill of Canvass-back Duck.

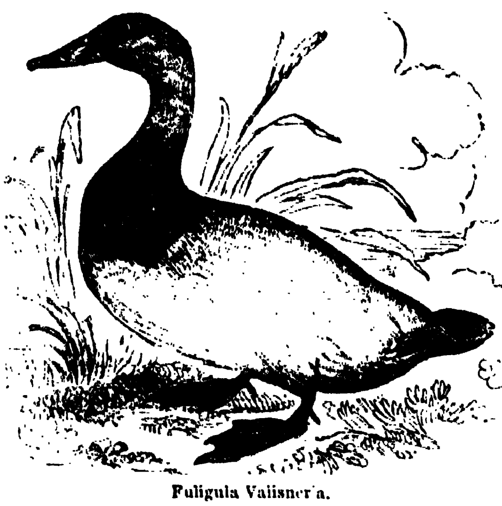
Geographical Distribution.—We have above given Dr. Richardson's account of its breeding from the 50th parallel to the most northern limits of the fur countries. When the work of incubation is past, flocks of Canvass-backs pursue their course to the southward, and arrive about the middle of October on the sea-coasts of the United States. The Hudson, the Delaware, and the bays of North Caro-

* Genus Aithya (Boié).

lina, are visited by some of these flocks; and it is stated that they are abundant in the river Neuse, in the vicinity of Newbern, and probably in most of the other southern waters down to the coast of the Gulf of Mexico, being seen in winter in the mild climate of New Orleans, at which season a few pairs arrive in Massachusetts Bay, near Cohasset and St. Martha's Vineyard. But it is to Chesapeake Bay, its æstuaries and rivers, among which the Susquehanna, the Patapsco, James's River, and the Potomac, may be particularly mentioned, that the great multitude of Canvass-back Ducks resort.—(Wilson; Nuttall.)

Habits, Food, &c. The canvass-backs associate with the pochards, and are waited upon by the bald-pates or wigeons (*Mareca Americana*), which rob them in the manner described in the article DUCKS (vol. ix. p. 183). They are named in different parts of the Union white-backs and sheldrakes, as well as canvass-backs. *Zostera marina* and *Ruppia maritima* form their food, as well as the fresh-water *Valisneria*, which last is limited in its distribution. The sea-wracks or eel-grass, as the long marine vegetables above alluded to are called in America, are widely spread over the Atlantic, and over the mud-flats, bays, and inlets where salt or brackish water finds access. The canvass-backs dive for and generally pluck up the sea-wrack, and feed only on the most tender portion near the root. They are very shy birds, and most difficult to be approached. Various stratagems are resorted to for getting within gunshot of them; and in severe winters artificial openings are made in the ice, to which the ducks crowd and fall a sacrifice to their eagerness to obtain food. That they will eat seeds and grain as well as sea-wrack, &c., was proved by the loss of a vessel loaded with wheat near the entrance of Great Egg Harbour, New Jersey, to which great flocks of canvass-backs were attracted. Upon this occasion as many as 240 were killed in one day. (Wilson; Nuttall.)

Utility to Man.—The canvass-back, which is lean on its first arrival in the United States, becomes, in November, about three pounds in weight, and in high order for the table: there are few birds which grace the board better. The Prince of Musignano is eloquent in its praise: 'Carne della massima squisitezza, grandemente ricercata dai gastronomi. La migliore delle Anitre. Forse il miglior uccello d'America.' Any attempt to introduce the bird into England would, it is feared, prove a failure: for even if the ordinary difficulties should be got over, the absence of the food to which it is supposed to owe its exquisite flavour would render the success of the experiment very doubtful.*

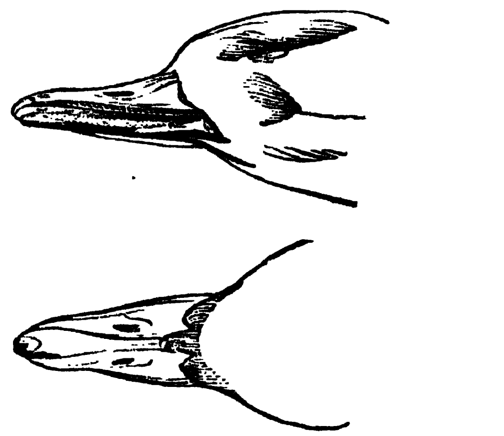


Fuligula Valisneria.

Clangula (Boié).

Bill narrow, elevated at the base, somewhat attenuated at the anterior extremity, and short. *Nostrils* inclining to oval, submesial, or rather anterior to the middle of the bill. *Tail* rather long, of 16 feathers generally.

Though many of this genus frequent the sea, the species are more generally met with in the fresh waters than the other Sea Ducks. Thus Dr. Richardson remarks that *Clangula vulgaris* (Common Golden Eye) and *albeola* (Spirit Duck) frequent the rivers and fresh-water lakes throughout the fur countries in great numbers. They are, as he states, by no means shy, allowing a near approach to the sportsman; but at the flash of a gun or even at the twang of a bow, they dive so suddenly that they are seldom killed. Hence the natives impute supernatural powers to them, as the appellations of 'Conjuring Ducks' and 'Spirit Ducks' sufficiently testify. Dr. Richardson says that the manners of *Clangula Barrovii* (Richardson and Swainson), described in 'Fauna Boreali-Americana,' and which has hitherto been found only in the valleys of the Rocky Mountains, do not differ from those of the Common Golden Eye. He speaks of *Clangula histrionica* as haunting eddies under cascades and rapid streams, as very vigilant, taking wing at once when disturbed, as rare, and as never associating, as far as he saw, with any other bird. The high northern latitudes may be considered generally as the localities of this genus,* which we proceed to illustrate by *Clangula albeola*, *Anas albeola* of Linnæus, the *Spirit Duck.*



Bill of Clangula albeola.

This is the *Buffel Duck* of Pennant; the *Buffel's Head Duck* of Catesby; the *Little black and white Duck* of Edwards; the *Buffel-headed Duck* of Wilson; *Wakaisheeweesheep*, *Waw haisheep*, and *Wappano-sheep* of the Cree and Chippeway Indians.

Dr. Richardson thus describes a male and female killed on the Saskatchewan in May, 1827.

Male.—Colour. Forehead, region of the bill, nuchal crest, and upper sides of the neck rich duck green, blending with the resplendent auricula-purple of the top of the head and throat. Broad band from the eye to the tip of the occipital crest, lower half of the neck, the shoulders, exterior scapulars, intermediate and greater coverts, outer webs of five or six secondaries, flanks, and under plumage to the vent pure white. Back, long scapulars, and tertiaries velvet black; lesser coverts bordering the wing the same, edged with white; primaries and their coverts brownish-black. Tail-coverts blackish-grey; tail broccoli-brown. Vent and under tail-coverts greyish. *Bill* bluish-black. *Legs* yellowish. In many spring specimens the under plumage is ash grey. *Form.—Bill* smaller in proportion than that of the common Garrot, and the nostrils nearer the base; but otherwise similar. *Head* large, with the upper part of the neck clothed in velvety plumage, rising into a short thick crest. Wings two inches and a half shorter than the tail. *Tail*—lateral feathers graduated, three middle pairs even. Length sixteen inches; but individuals differ in size.

Female.—Considerably smaller. Head and dorsal plumage dark blackish-brown; the forepart of the back, scapulars, and tertiaries, edged with yellowish brown. Fore part of the neck, sides of the breast, flanks, and vent-feathers, blackish-grey; breast and belly white, glossed with brownish-orange. White band on the ears and occiput much narrower than in the male. The white speculum is less perfect, and the whole of the lesser coverts and scapulars are unspotted blackish-brown. *Bill* and *feet* brownish. Total length fourteen inches and a half.

Young males resemble the females. ('Fauna Boreali-Americana.')

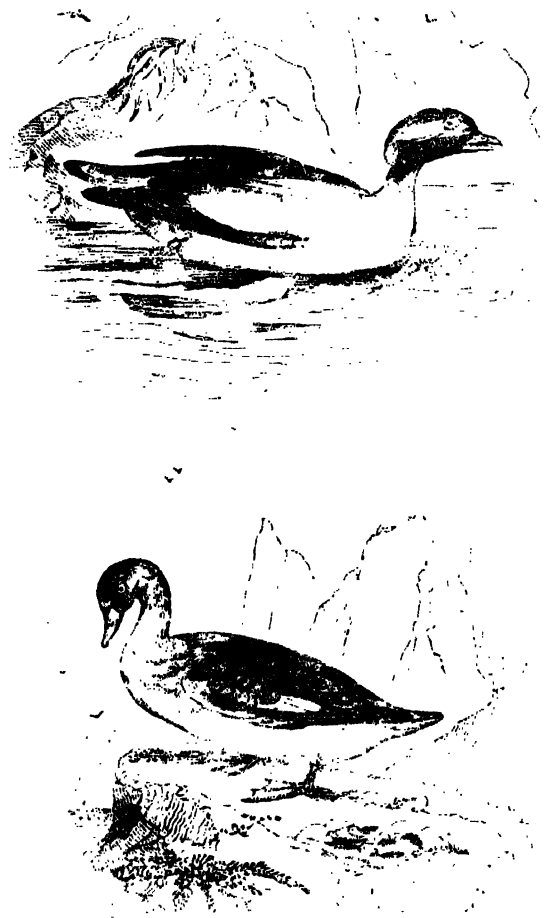
* The Western Duck (*Fuligula Stelleri*) has been elevated to a genus by Brehm under the name of *Callicher*.

* The Common Golden Eye, or Garrot (*Clangula vulgaris*, *Anas Clangula*, Linn.) is an inhabitant of the Arctic regions of the new and old worlds, and frequently met with in this country, and in Europe generally. The species is distributed over the Swiss lakes. Mr. Gould figures Clangula Barrovii and Clangula histrionica among the Birds of Europe, the former having been shot in Iceland by T. C. Atkinson, Esq., and the latter having been frequently captured in the British Islands.

Geographical Distribution.—**Abundant in the summer on the rivers and fresh-water lakes of the fur countries. In autumn and winter very common in the United States, sometimes on the sea-shores. Catesby says that the Buffel's Head Duck appears in Carolina during the winter only. On the river Neuse, in North Carolina, they have been seen in abundance in February. In April and May those in the south take their departure northward.**

Habits, Food, Re-production.—This species is a most expert diver, whether it resorts to that feat as a mode of escape, or as the means of procuring the sea-wrack and laver (*Ulva lactuca*), and crustaceans and mollusks, which, at particular seasons of the year when it visits the sea bays and salt marshes, form its favourite food. The rapidity of its disappearance from the surface, and the artful way in which it conceals itself after it has vanished under water, have earned for it the appropriate name of 'Spirit Duck,' or 'Conjurer.' A bird is rarely hit, and when it is, if not killed outright, it can rarely be captured; so quick is the Spirit Duck in avoiding the shot altogether, and so dexterous in evading its pursuer, if only wounded. About Hudson's Bay they are said to form their nests in hollow trees in woods adjacent to water. (Wilson; Nuttall).

Utility to Man.—The flesh of the Spirit Duck is not in high repute but the females and young are tender and well-flavoured in the winter. The bird becomes so fat that, in Pennsylvania and New Jersey, it is commonly called 'Butter-Box,' or 'Butter-Ball.'

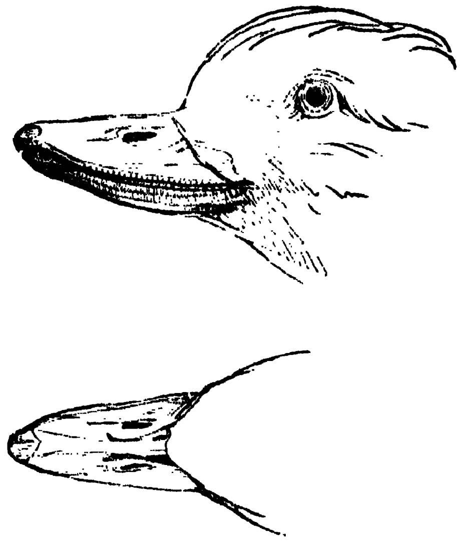


Clangula albeola, male and female.

Harelda. (Leach).

Generic Character.—*Bill* very short, high at the base, nail broad and arched. *Laminæ* prominent, trenchant, and distant; the upper laminæ projecting below the margin of the mandible, the lower laminæ divided into a nearly equal double series. *Nostrils* oblong, large, and nearly basal. Forehead high; neck rather thick. *Tail* very long, of fourteen feathers. *Toes* short.

Example, *Harelda glacialis, Anas glacialis*, Linn., the *Long-tailed Duck.*



Bill of Harelda glacialis.

This is the *Canard à longue Queue, ou Canard de Miclon* of the French; *Eisente, Winter Ente* of the Germans; *Ungle, Angeltaske, Trasfoener* of the Norwegians; *Oedel* of the Feroe Islanders; *Ha-Old, Ha-Ella* of the Icelanders; *Swallow-tailed Sheldrake, Sharp-tailed Duck, Calao, Calaw, Coal and Candle Light* of the modern British; *Hwyad gynffon gwennol* of the antient British; *Old Wife* and *Swallow-tailed Duck* of the Hudson's Bay residents; *South-Southerly* of the United States; *Ahdggee-areoo* of the Esquimaux; *Caccâwee* of the Canadian voyageurs; and *Hahhaway* of the Cree Indians.

Description.—Old Male (Winter). Summit of the head, nape, front, and lower parts of the neck, long scapulars, belly, abdomen, and lateral tail feathers, pure white; cheeks and throat ash-colour; a great space of maroon brown on the sides of the neck; breast, back, rump, wings, and the two long feathers of the middle of the tail brownish; flanks ash-coloured; the black of the bill cut transversely by a red band; tarsi and toes yellow; webs blackish; iris orange. Length, comprising the long tail-feathers, twenty to twenty-one inches.

Old Female. Differing much from the male. Tail short, the feathers bordered with white and the two middle ones not elongated; forehead, throat, and eyebrows whitish ash; nape, front, and lower part of the neck, belly, and abdomen pure white; top of the head and great space at the sides of the neck blackish ash; breast variegated with ash colour and brown; feathers of the back, scapulars, and wing-coverts black in the middle, bordered and terminated with ashy-red; rest of the other parts brown; the bluish colour of the bill cut by a yellowish band; iris bright brown; feet lead-colour. Length 16 inches.

Young of the Year. Not differing much from the old female; the whiteness of the face is varied with numerous brown or ash-coloured spots; throat, front of the neck, and nape ashy-brown; lower part of the neck, a large spot behind the eyes, belly, and abdomen white; breast and thighs variegated with brown and ash-coloured spots. (Temminck.)

Summer Dress.—Male, killed May 1, 1826, on the Saskatchewan. *Colour.*—The whole upper plumage, the two central pairs of tail feathers, and the under plumage to the fore part of the belly brownish-black; the lesser quills paler. A triangular patch of the feathers between the shoulders, and the scapulars, broadly bordered with orange brown. Sides of the head from the bill to the ears ash-grey; eye-stripe and posterior under plumage pure white. Flanks, sides of the rump, and lateral tail-feathers white, stained with brown; axillaries and inner wing-coverts clove-brown. *Bill* black, with an orange belt before the nostrils. *Legs* dark-brown. Specimens killed a fortnight or three weeks later in the season at Bear Lake, on their way to the breeding-places, differed in having a large white patch on the hind head and occiput, with scattered white feathers on the neck and among the scapulars; the sides under the wings pure pearl grey, and the sides of the rump unstained white. (Dr. Richardson, 'Fauna Boreali-Americana.')

Captain, now Major, Edward Sabine (Supplement to Appendix of Captain Sir W. E. Parry's First Voyage) notices

a male obtained in June, corresponding precisely with the individual killed in Baffin's Bay in the summer of 1818, which furnished the description of the full breeding plumage in the 'Memoir of the Greenland Birds.' An account, adds the author, of this state of plumage is yet wanting to complete the history of this species in M. Temminck's second edition. The plumage of a young male killed on the 22nd of June corresponded precisely with M. Temminck's male of one or two years old. Dr. Richardson observes (*loc. cit.*) that Captain Sabine describes the plumage of the specimens killed at Bear Lake as the pure breeding plumage; but individuals coloured like the one killed on the Saskatchewan are, he remarks, often seen at the breeding stations. He quotes Mr. Edwards, surgeon of the Fury (Sir W. E. Parry's 2nd Voyage), as describing the Long-tailed Ducks killed at Melville Peninsula between the 1st and 25th of June as follows:—They had all a dark silky chestnut-brown patch on the side of the neck; a mixture of white in the black stripe from the bill to the crown; the crown and nape either entirely white, or mixed with black; scapulars and upper tail-coverts edged with white; a broad white collar round the lower part of the neck, in some individuals tipped with black or brown; occasionally a white band on the breat. The colour of the belt on the bill varied from rose-red to violet.

Mature Female, killed May 25, lat. $65\frac{1}{2}$°. *Upper plumage* and sides of the breast pale liver-brown, with dark centres; the wing-coverts, scapulars, and hinder parts mostly edged with white. Top of the head blackish-brown, its sides anteriorly broccoli-brown; ears and base of the neck below clove brown. A spot at the base of the bill and a stripe behind the eye white. Throat and collar ash-grey. Tail-feathers brownish-grey, edged with white, short and worn. (Dr. Richardson.)

Geographical Distribution.—The Arctic seas of both worlds. An accidental visitor on the great lakes of Germany, and along the Baltic. Often, but never in flocks, on the maritime coasts of Holland. (Temminck.) Abundant in Sweden, Lapland, and Russia. (Gould.) Noted in the list of birds seen within the Arctic Circle and as breeding in the North Georgian Islands, but not common there. (Supplement to Appendix to Captain Parry's First Voyage.) Females taken in Duke of York's Bay. (Captain Lyon's Journal.) Abundant on the Arctic Sea, associating with the *Oidemiæ*, remaining in the north as long as it can find open water, and assembling in very large flocks before migrating. Halts, during its progress southwards, both on the shores of the Hudson's Bay and in the inland lakes, and is one of the last of the birds of passage which quits the fur countries. (Dr. Richardson, 'Fauna Boreali-Americana.') Captain James Ross describes it as the most noisy and most numerous of the ducks that visit the shores of Boothia. (Appendix to Captain Sir John Ross's Last Voyage.) The species is abundant in Greenland, Lapland, Russia, and Kamtchatka, and flocks pass the winter (from October to April) at the Orkney Islands. They are seldom seen in the southern parts of England, unless the weather be very severe. In October they visit the United States, and abound in Chesapeake Bay.

Habits, Food, Reproduction, &c.—Lively, most noisy, and gregarious, the Long-tailed Duck, with its swallow-like appearance in flight, swims and dives with all the expertness of the Spirit Ducks. Dr. Richardson states that in the latter end of August, when a thin crust of ice forms during the night on the Arctic Sea, the female may be often seen breaking a way with her wings for her young brood. The same author states that the eggs are pale greenish-grey, with both ends rather obtuse, 26 lines long and 18 wide. They are about five in number; and in Spitzbergen, Iceland, and along the grassy shores of Hudson's Bay, near the sea, this species is said to form its nest, about the middle of June, lining the interior with the down of the breast. Marine productions principally, both animal and vegetable, form its food, particularly the *Zostera*, or Grass-wrack, for which it dives like others of its congeners. 'Late in the evening, or early in the morning,' writes Nuttall in his *Manual*,* 'towards spring more particularly, vast flocks are seen in the bays and sheltered inlets, and in calm and foggy weather we hear the loud and blended nasal call reiterated for hours from the motley multitude. There is something in the sound like the honk of the goose, and, as far as words can express a subject so uncouth, it resembles the guttural syllables *ogh, ough, egh,* and then *ogh, ogh, ogh, ough, egh,* given in a ludicrous drawling tone; but still, with all the accompaniments of scene and season, this humble harbinger of spring, obeying the feelings of nature, and pouring forth his final ditty before his departure to the distant north, conspires, with the novelty of the call, to please rather than disgust those happy few who may be willing to find "good in everything."'

Utility to Man.—The old birds are not considered as of much value for the table; but the young birds are tender and juicy. If, as is on good authority asserted, the down which the *Long-tailed Duck* strips from its breast as a lining for the nest is as soft and elastic as that of the *Eider Duck*, it may considered as offering no mean contribution to the comforts of man, a contribution which, however apparently hitherto neglected, deserves the attention of the intelligent and enterprising.

Harelda glacialis: male and female.

In addition to the genera above-mentioned, *Gymnura* (*Oxyura* of Bonaparte), *Macropus*, and *Micropterus* find a place among the *Sea Ducks*.

The species from which the genus *Oxyura* is established is bred, according to Nuttall ('Manual'), in the north, and principally haunts fresh-water lakes, diving and swimming with great ease, but it is averse to rising into the air. It is small, and is said, by the last-named author, to be nearly allied to *Anas leucocephala*, which inhabits the saline lakes and inland seas of Siberia, Russia, and the east of Europe; and also to have an affinity with *A. Jamaicensis* of Latham. Nuttall thinks that it is perhaps identical with *A. spinosa* of Guiana, if not also with *A. Dominica* of Gmelin, a native of St. Domingo, and probably only resident there during the winter. He also observes that the name of *Oxyura* having been previously employed for a sub-genus of Creepers, it was necessary to alter it; but the student should remember that *Gymnura* had been preoccupied by Sir Stamford Raffles for a genus of mammifers; and that Spix has named a family of South American monkeys *Gymnuri*. The Prince of Musignano, however, corrected

* 'Manual of the Ornithology of the United States and of Canada,' 2 vols., 8vo., Boston. A most useful and interesting book.

himself and changed the name to *Erismatura.* Mr. Gould gave the name of *Undina* to the genus, and figures the European species under the name of Undina leucocephala.

It should be remembered that the subgeneric term *Macropus* has been long applied as a generic name for the Kangaroos.

Micropterus is the genus containing the well-known *Race-Horse* of Cook (*Micropterus brachypterus, Anas brachyptera* of authors). Captain Phillip Parker King, R.N., who has added a second species (*Micropterus Patachonicus*), gives these short-winged but rapidly progressing Sea Ducks the familiar name of Steamer Ducks or Steamers.

At a meeting of the Zoological Society, in December 1837, Mr. T. C. Eyton made some observations on the *Anatidæ*, which family he regarded as connected with the *Grallatorial Birds* by means of the *Flamingo* on the one side and the *semipalmated Goose* on the other, with the *Divers* of the family *Alcadæ* by the *Mergansers*, and also with the *Cormorants* through the *Erismaturinæ*. Mr. Eyton divides the *Anatidæ* into the subfamilies *Plectropterinæ, Anserinæ, Anatinæ, Fuligulinæ, Erismaturinæ*, and *Merginæ*.

The *Anatinæ*, according to Mr. Eyton, contain the following genera: *Tadorna*, Leach; *Casarka*, Bonaparte; *Dendrocygna*, Swainson; *Leptotarsis*, Gould (*L. Eytoni*); *Dafila*, Leach; *Mareca*, Stephens; *Aia*, Boié (Anas sponsa, Linn.); *Pœcilonetta*, Eyton (*Anas marmorata*, Temm.); *Querquedula*, Auct.; *Cyanopterus* (*Anas Rafflesii*, King); *Rhynchaspis*, Leach; *Malacorhynchus*, Swainson; *Chauliodus*,* Swainson; *Anas*, Auct.; *Carina*, Fleming.

Mr. Eyton's *Fuligulinæ* consist of the genera *Micropterus*, King; *Melanitta*, Boié; *Somateria*, Leach; *Polysticta*, Eyton (Anas dispar, Gmel.); *Kamptorhynchus*, Eyton (*Anas Labradora*, Wilson); *Callicher*, Brehm; *Fuligula*, Ray; *Nyroca*, Fleming; *Harelda*, Leach; and *Clangula*, Leach.

Mr. Eyton stated, that characters of the genera and species would be given in his forthcoming monograph on the *Anatidæ*.

FULLER, THOMAS, was the son of the Rev. Thomas Fuller, rector of Aldwincle, in Northamptonshire, where he was born in 1608. He was educated under his father, and was sent at the early age of twelve years to Queen's College, Cambridge. He became B.A. in 1625, and M.A. in 1628, but afterwards removed to Sidney College, where he obtained a fellowship in 1631, and nearly at the same time the prebend of Netherby, in the church of Salisbury. In this year also he issued his first publication, a poem, now little known, entitled 'David's Hainous Sin, Hearti Repentence, Heavie Punishment,' in 12mo. He was soon after ordained priest, and presented to the rectory of Broad Windsor, in Dorsetshire: but growing weary of a country parish, and uneasy at the unsettled state of public affairs, he removed to London, and distinguished himself so much in the pulpits there, that he was invited by the master and brethren of the Savoy to be their lecturer. In 1639 he published his 'History of the Holy War:' it was printed at Cambridge, in folio, and so favourably received that a third edition appeared in 1647. On April 13, 1640, a parliament was called, and a convocation also began at Westminster, in Henry VIIth's chapel, having licence granted to make new canons for the better government of the church: of this convocation he was a member, and has detailed its proceedings in his 'Church History.' During the commencement of the Rebellion, and when the king left London, in 1641, to raise an army, Mr. Fuller continued at the Savoy, to the great satisfaction of his congregation and the neighbouring nobility and gentry, labouring all the while in private and in public to serve the king. On the anniversary of his inauguration, March 37, 1642, he preached at Westminster Abbey on this text, 2 Sam. xix. 30, 'Yea, let him take all, so that my lord the king return in peace,' which, being printed, gave great offence to those who were engaged in the opposition, and exposed the preacher to a good deal of danger.

In 1643, refusing to take an oath to the parliament, unless with such reserves as they would not admit, in April of that year he joined the king at Oxford, who, having heard of his extraordinary abilities in the pulpit, was desirous of knowing them personally, and accordingly Fuller preached before him at St. Mary's Church. He had before preached and published a sermon in London, upon the 'new-moulding church-reformation,' which caused him to be censured as too hot a royalist; and now, from his sermon at Oxford, he was thought to be too luke-warm, which can only be ascribed to his moderation, which he would sincerely have inculcated upon each party as the only means of reconciling both. During his stay here, his residence was in Lincoln College, but he was not long after sequestered, and lost all his books and manuscripts. This loss, the heaviest he could sustain, was made up to him partly by Henry Lord Beauchamp, and partly by Lionel Cranfield, earl of Middlesex, who gave him the remains of his father's library. That, however, he might not lie under the suspicion of want of zeal or courage in the royal cause, he determined to join the army, and therefore, being well recommended to Sir Ralph Hopton in 1643, he was admitted by him in quality of chaplain. For this employment he was at liberty, being deprived of all other preferment. Though he attended the army from place to place, and constantly exercised his duty as chaplain, he yet found proper intervals for his favorite studies, which he employed chiefly in making historical collections, and especially in gathering materials for his 'Worthies of England,' which he did, not only by an extensive correspondence, but by personal inquiries in every place which the army had occasion to pass through.

After the battle at Cheriton-Down, March 29, 1644, Lord Hopton drew on his army to Basing-House, and Fuller, being left there by him, animated the garrison to so vigorous a defence of that place, that Sir William Waller was obliged to raise the siege with considerable loss But the war coming to an end, and part of the king's army being driven into Cornwall under Lord Hopton, Fuller, with the permission of that nobleman, took refuge at Exeter, where he resumed his studies, and preached constantly to the citizens. During his residence here he was appointed chaplain to the infant princess, Henrietta Maria, who was born at Exeter in June, 1643. He continued his attendance on the princess till the surrender of Exeter to the parliament, in April, 1646. He is said to have written his 'Good Thoughts in Bad Times' at Exeter, where the book was published in 1645, 16mo. On the garrison being forced to surrender, he came to London, where he found his lectureship at the Savoy filled by another. It was not long however before he was chosen lecturer of St. Clement's, near Lombard Street, and shortly afterwards removed to St. Bride's, Fleet Street. In 1647 he published, in 4to., 'a Sermon of Assurance, fourteen years ago preached at Cambridge, since in other places, now by the importunity of his friends exposed to public view.' He dedicated it to Sir John Danvers, who had been a royalist, was then an Oliverian, and next year one of the king's judges: and in the dedication he says, that 'it had been the pleasure of the present authority to make him mute, forbidding him, till further order, the exercise of his public preaching.' Notwithstanding his being thus silenced, he was, about 1648, presented to the rectory of Waltham Abbey, in Essex, by the earl of Carlisle. In 1648 he published his 'Holy State,' folio, Cambr. His 'Pisgah-sight of Palestine and the Confines thereof, with the History of the Old and New Testament, acted thereon,' was published, fol. Lond. 1650, and reprinted in 1662. At this period he was still employed upon his 'Worthies.' In 1651 he published 'Abel Redivivus, or the Dead yet Speaking; the Lives and Deaths of the Modern Divines.' Lond. 4to. In the two or three following years he printed several sermons and tracts upon religious subjects: 'The Infant's Advocate,' 8vo. Lond. 1653; 'Perfection and Peace, a Sermon,' 4to. Lond. 1653 'A Comment on Ruth, with two Sermons,' 8vo. Lond. 1654; 'A Triple Reconciler,' 8vo. Lond. 1654. About this last year he took as a second wife a sister of the Viscount Baltinglasse. In 1655, notwithstanding Cromwell's prohibition of all persons from preaching or teaching school who had been adherents to the late king, he continued preaching and exerting his charitable disposition towards those ministers who were ejected, as well as towards others. In 1655 he published in folio 'The Church History of Britain, from the birth of Jesus Christ until the year MDCXLVIII.,' to which he subjoined 'The History of the University of Cambridge since the Conquest,' and 'The History of Waltham Abbey, in Essex, founded by King Harold.' The Church History was animadverted upon by Dr. Peter Heylyn in his 'Examen Historicum,' to which

* Pre-occupied by Schneider for a genus of Fishes—Chauliodus Sloani, Schn., Esox stomias, Sh.

Fuller replied in his 'Appeal of Injured Innocence,' fol. Lond. 1659. It is said that Lord Berkeley, in 1658 or 1659, took him over to the Hague, and introduced him to Charles II. It is certain however that a short time before the Restoration he was re-admitted to his lecture in the Savoy, and on that event restored to his prebend of Salisbury. He was chosen chaplain extraordinary to the king; and created D.D., at Cambridge, by a mandamus dated Aug. 2, 1660. Upon his return from Salisbury, in August, 1661, he was attacked by a fever, of which he died on the 15th of that month. His funeral was attended by at least two hundred of his brethren of the ministry. He was buried in his church of Cranford, on the north wall of the chancel of which his monument is still remaining. His 'History of the Worthies of England' was not published till after his death, fol. Lond. 1662: reprinted in two volumes, 4to. Lond. 1811, with explanatory notes by John Nichols. The University of Oxford intend publishing another reprint of this work.

Besides the works already mentioned, Fuller was the author of several others of a smaller kind. 1. 'Andronicus, or the Unfortunate Politician,' 12mo. Lond. 1646. 2. 'Good Thoughts in Worse Times,' 16mo. Lond. 1647, reprinted with his 'Good Thoughts in Bad Times,' 1652, and again, 12mo. Lond. 1669, and both since reprinted at Oxford; 3. 'Mixt Contemplations in Better Times,' 12mo. Lond. 1660; 4. 'The Speech of Birds, also of Flowers, partly moral, partly mystical,' 8vo. 1660. In 1651 he published Dr. Holdsworth's 'Valley of Vision,' with a preface. A specimen of his Latin composition, in what is called 'An Eccho,' occurs in the first book of 'Ayres and Dialogues, for one, two, and three Voyces,' by Henry Lawes, fol. Lond. 1653. Fuller was a man of great wit, and of powers of memory almost incredible. (*Life of Dr. Thomas Fuller*, 12mo. Lond. 1661; *Biogr. Britan.*, vol. iii. 2049—2069: Chalmers's *Biogr. Dict.*, vol. xv. p. 168—176.)

FULLERS' EARTH, a mineral product, formerly much used in the fulling of cloth, whence it derives its name. It occurs massive, and is usually of a greenish brown or dull grey colour; sometimes it is nearly of a slate colour. It is opaque, dull, and its specific gravity is 1·8, 2·2. Greasy and soft, yielding to, and polished by, the nail. Fracture uneven, earthy; in water it breaks down into a soft pulpy mass. Before the blow-pipe it fuses into a white blobby glass.

It is found at Nutfield, near Reigate, in Surrey, and occurs in regular beds near the summit of a hill, between beds of sand or sandstone, containing fossil wood, cornua ammonis, &c. There are two distinct beds of fullers' earth; the upper has a greenish colour, is five feet in thickness, and rests upon the other, which has a bluish tint, and is eleven feet thick; in these beds, but especially in the latter, there are found considerable masses of sulphate of barytes, frequently in regular crystals. Fullers' earth is also found in Kent, Bedfordshire, Bath, Nottinghamshire, and Sussex. It is met with also in Styria, Saxony, and some other places.

According to Dr. Thomson's analysis, this substance consists of

Silica	44	
Alumina	23·06	
Lime	4·08	
Magnesia	2·00	
Protoxide of iron	2·00	
Water	24·95	
		100·09

Dr. Thomson observes that, allowing the lime, magnesia, and protoxide of iron, to be in the state of silicates, and as mere accidental constituents, fullers' earth is a hydrous bisilicate of alumina, consisting of 2 equivalents of silica, 1 equivalent of alumina, and two equivalents of water.

FULLING. [WOOLLEN MANUFACTURES.]

FULMINATING POWDERS. [DETONATION.]

FULMINIC ACID. An acid which appears to be isomeric with cyanic acid [CYANIC ACID], that is, composed of the same elements in the same proportions, and they appear to have similar saturating powers. Fulminic acid is that which exists in the detonating mercury and silver discovered by Mr. Howard. These fulminates, as shown under the respective metals, are prepared by the simultaneous action of nitric acid and alcohol upon them: in this operation the metals are oxidized, and such portions of the carbon, of the alcohol, and azote and oxygen of the decomposed nitric acid combine, as to form the fulminic acid, which may be regarded as composed of

$$\left.\begin{array}{ll}\text{Two equivs. of carbon} & 12\\ \text{One do. azote} & 14\end{array}\right\} = \text{One equiv. cyanogen} \quad 26$$

$$\text{One do. oxygen} \quad 8$$

$$\text{Equivalent} \quad 34$$

The subject of the perfect identity of the cyanic acid and fulminic acid is, however, obscure; and as their combining weight is similar, we have not the resource available in the case of the isomeric carburetted hydrogens, of supposing that they consist of the same proportions, but of a different number of equivalents of the same elements. Fulminic acid may be separated from the oxides of silver and of mercury, and combined with other bases, as with potash, and it still retains its power of forming detonating compounds.

FULTON, ROBERT, distinguished as having been the first to establish steam-navigation on the American seas and rivers, was born in 1765, in Little Britain, Pennsylvania. His parents were emigrants from Ireland. He received a common English education at a village school. Besides a fondness for mechanical pursuits, he early displayed a taste for drawing, and in his eighteenth year went to Philadelphia, and began to paint portraits and landscapes as a means of subsistence.

In November, 1786, he embarked for England, and on his arrival in London was received as an inmate in the house of West, the historical painter, with whom he continued to reside for some years, and who also gave him instructions in his profession.

After leaving West, painting was for some time his chief employment. But with Fulton the fine arts were destined to give place to the mechanical. He spent about two years in Devonshire, where he became acquainted with the Duke of Bridgewater, and projects for the improvement of canals then began to occupy the chief share of his attention. In 1794 he took out a patent for an inclined plane, which was intended to set aside the use of locks; he invented a machine to facilitate excavation, and wrote a work on canals, in which he first styled himself a civil engineer. He also invented a mill for sawing marble, and took out patents for spinning flax and making ropes.

He seems however to have had little success; and at the latter end of 1796 went to Paris, on the invitation of Joel Barlow, then resident minister from the United States, in whose house he resided during seven years. While at Paris two projects appear to have occupied a large portion of his time and attention; one, a carcass, or box filled with combustibles, which was to be propelled under water, and made to explode beneath the bottom of a vessel; the other, a submarine boat, to be used for a similar destructive purpose. The first was a failure; but of his submarine boat he made many trials and exhibitions, some of them at the expense of the French government, with occasional failures and partial success, on the Seine, at Hâvre, and at Rouen. But for all practical purposes this was as much a failure as the other. He appears however to have clung to it with great perseverance, and not long before his death exhibited its power by blowing up an old vessel in the neighbourhood of New York.

But while at Paris he had other and better pursuits. He made himself acquainted with the higher branches o. science, and with the modern European languages: he projected the first panorama exhibited at Paris, and in conjunction with Mr. R. Livingston, the American ambassador, began to make experiments on the Seine with small steamboats: a larger one was built, which broke asunder, but a second, completed in 1803, was successful.

Soon after this time he was invited to England by the English ministry, at the suggestion of Earl Stanhope, with whom Fulton had become acquainted about the time of his introduction to the Duke of Bridgewater. The object of the English ministry appears to have been to employ him in the construction of his submarine implements of war. After some trials on the Thames, the negotiation failed, and Fulton resolved to embark for America.

In 1806 Fulton arrived at New York, and soon after, with funds supplied by Mr. Livingston, commenced the construction of a steam-vessel of considerable size, which began to navigate the Hudson in 1807. He afterwards built others of large dimensions, one of them a frigate, which bore his name. His reputation became established, and his fortune was rapidly increasing, when his patent for steam-vessels, which he had taken out in conjunction with

Mr. Livingston, was disputed, and his opponents were, in a considerable degree, successful. His constitution had been impaired by his numerous labours, and a severe cold which he caught by incautious exposure in giving directions to his workmen, together with the anxiety and fretfulness occasioned by the law-suits about his patent rights, brought his life to a premature termination on the 24th of February, 1815, in his forty-ninth year. His death occasioned extraordinary demonstrations of national mourning in the United States.

In person he was tall, and though slender, well formed. He appears to have been an amiable, social, and liberal man. (*Encyclopædia Americana; Dictionnaire de la Conversation.*)

FUMARIACEÆ, a small natural order of Exogenous plants, consisting of slender-stemmed, herbaceous plants, many of which scramble up others by aid of their twisting leafstalks. They are rather succulent in texture, with watery juice. Their leaves, which have no stipules, are repeatedly divided till the terminal lobes become small ovate leaflets; their flowers, which are extremely irregular, consist of two membranous, minute, ragged sepals, two exterior distinct linear petals, and two others, which hold firmly together at the points; there are six stamens united into two parcels, and the ovary is a one-celled case with one or many seeds, whose placentation is parietal; finally, the seeds consist principally of albumen, in which there ripens a very small embryo. *Fumaria officinalis* is one of the commonest of weeds; many are objects of cultivation by the gardener for the sake of their showy flowers; all are reputed diaphoretics. They only inhabit the cooler parts of the world, alike avoiding extremes of heat or cold. It is probable that notwithstanding the diversity of their appearance they are only a low irregular form of Papaveraceæ.

1 3 2

Corydalis lutea.

1. the two sepals, stamens, and pistil; 2, a longitudinal section of the ovary; 3, a longitudinal section of a seed, showing the ovary: all more or less magnified.

FUMIGATION is the application of the vapour or fumes from metallic or other preparations to the body, with the intention of healing either generally, or particular parts. The vapours of hot vinegar, burning sulphur, and of aromatic vegetable matters, have been long used to counteract unpleasant or unwholesome smells: this is effected chiefly by the formation of such as are stronger. The most important kind of fumigation is that which consists in the employment of such vapours or gases as do not merely destroy unhealthy odours by exciting such as are more powerful, but which by their chemical action convert dangerous miasmata into innocuous matter.

The fumigation of the first kind, that which is intended to produce a healing effect, is now much less employed than formerly: still, however, the bisulphuret of mercury is occasionally used in vapour, as what is termed a mercurial fumigation, in certain forms of syphilis. The use of vinegar, of aromatic pastilles, and even the smoke of burning brown paper, which constitute the second kind of fumigation, does not require any particular notice; their operation can hardly be regarded as any other than that of substituting one smell for another. In the last kind of fumigation three substances have been chiefly employed, and in the gaseous state: first, the vapour of burning sulphur, or sulphurous acid gas, muriatic acid gas, nitric acid gas, and chlorine gas; all but the last of these, or at any rate the first and second named, appear to have been first used and recommended by Dr. James Johnstone of Worcester, about the year 1758; in 1773 Guyton de Morveau also mentioned the application of muriatic and nitric acid gases, and in 1802 their use was still further extended by Dr. J. C. Smith, who received a public remuneration as the discoverer, which he certainly was not.

Chlorine gas, which is undoubtedly preferable to any disinfectant, was first recommended by Dr. Rollo, who published a work on diabetes in 1797; he liberated the gas by the usual method of mixing sulphuric acid, binoxide of manganese, and common salt. When it is desirable to produce a great effect in a short time, this is still unquestionably the best mode of proceeding.

We shall give an abstract of the mode adopted by Mr. Faraday in fumigating the Penitentiary at Milbank in 1825. (*Quarterly Journal*, vol. xviii., p. 92.)

The space requiring fumigation amounted to nearly 2,000,000 cubic feet: and the surface of the walls, floors, ceilings, &c., was about 1,200,000 square feet. This surface was principally stone and brick, most of which had been lime-washed. A quantity of salt reduced to powder was mixed with an equal weight of binoxide of manganese, and upon this mixture were poured two parts of sulphuric acid, previously diluted with one part of water, and cold. The acid and water were mixed in a wooden tub, the water being first put in, and it being more convenient to measure than to weigh the water and acid, ten measures of water and nine of acid were used; half the acid was first used, and when the mixture had cooled the remainder was added.

Into common red earthen pans, each capable of holding about a gallon, were put 3½ lbs. of the mixed salt and manganese, and there was then added such a measure of the diluted acid as weighed 4½ lbs.; the mixture was well stirred and then left to itself, and all apertures were well stopped. The action did not commence immediately, so that there was sufficient time for the operator to go from pan to pan without inconvenience. On entering a gallery 150 feet in length, a few minutes after the mixture had been made, the general diffusion of chlorine was sufficiently evident; in half an hour it was often almost impossible to enter, and frequently on looking along the gallery the yellow tint of the atmosphere could easily be perceived. Up to the fifth day the colour of the chlorine could generally be observed in the building; after the sixth day the pans were removed, though sometimes with difficulty, and the gallery thus fumigated had its windows and doors thrown open. The charge contained in each pan was estimated to yield about 5½ cubic feet of chlorine gas; in fumigating a space of 2,000,000 cubic feet, about 700 lbs. of common salt and the same of binoxide of manganese were employed; and it will appear by a slight calculation, that about 1710 cubic feet of chlorine were employed to disinfect this space. In common cases, Mr. Faraday conceives that about one-half to one-fourth of this quantity of chlorine would be sufficient.

When any cause is continually recurring, and in some cases almost imperceptibly so, the chloride of lime or soda, and especially of the former, has been within a few years successfully employed by M. Labarraque; the exact nature of these compounds is still under discussion, but the chloride of lime is a substance well known and extensively employed under the name of bleaching-powder.

We shall relate a few experiments performed by M. Gaultier de Claubry, illustrative of the mode in which these substances produce their effects. A solution of chloride of lime exposed to the air for about two months, ceased to act upon litmus, contained no chlorine, but a precipitate was formed in it which consisted entirely of carbonate of lime, without any admixture of chlorine; it was therefore evident that the carbonic acid of the atmosphere had decomposed the chloride of lime, evolved the chlorine, and precipitated the lime. That this was the case was proved by passing atmospheric air through a solution of potash, before it was made to traverse one of chloride of lime; in this case the

potash separated the carbonic acid, so that no chlorine was evolved from the solution of chloride of lime, nor was any precipitate formed in it; in fact no change whatever occurred. That it was the carbonic acid which produced this effect, was further proved by passing a current of this gas into a solution of chloride of lime; by this it lost its bleaching power, the whole of the chlorine was expelled, and all the lime converted into carbonate.

In order to show the manner in which these compounds of chlorine and lime, and of chlorine and soda, act on putrid miasmata floating in the air, some further experiments were made in the following manner:—Air was passed through blood which had been left to putrefy for eight days; being then passed through a solution of the chloride of lime, carbonate of lime was deposited, and the air was rendered inodorous and completely purified. In a second similar experiment the fetid air was passed through a saturated solution of potash before it arrived at the solution of chloride of lime; the latter had then no effect upon it, and the air retained its insupportable odour; this happened evidently because the carbonic acid, which would otherwise have evolved chlorine to have acted upon the putrid matter, was absorbed by the potash. Another experiment was made with air left for twenty-four hours over putrescent blood; the portion of it which was passed directly through the chloride was perfectly purified, but when previously freed from carbonic acid the chloride had no effect upon it.

These experiments sufficiently prove that the carbonic acid in the air, arising from the various sources of respiration, combustion, and the decomposition of animal and vegetable matter, liberates the chlorine from its combination with lime or soda; and as this action is slow, the chlorine, though scarcely susceptible of affecting the animal economy, readily decomposes putrid miasmata. It is therefore true fumigation by chlorine, only it is less violent than that effected by the rapid evolution of the gas, and it continues for a longer time.

It is to be observed that chloride of lime is used in solution, and is obtained by dissolving one part of bleaching powder in about 100 times its weight of water, and allowing the solution to become clear. This is to be exposed to infected air, or in rooms which have any unpleasant odour, in flat vessels, in order that a sufficient surface may be acted upon. If it should be required, the operation may be quickened by the addition of a little vinegar, or of muriatic acid largely diluted. In some cases, where the disagreeable is extremely strong, and where it would be difficult to expose a solution to slow action, it may be thrown into the place, or the powder may be used, the action of which would be more gradual and effectual. Chloride of soda is prepared only in solution; the process is given in the last edition of the London Pharmacopœia: it is however less easily obtained than the chloride of lime, is more expensive, and not in any respect preferable; the solution is then called liquor sodæ chlorinatæ.

FUNCHAL. [Madeira.]

FUNCTIONS, CALCULUS OF. By the term *function of a quantity* is meant any algebraical expression, or other quantity expressed algebraically or not, which depends for its value upon the first. Thus the circumference of a circle is a function of the radius; the expression $(a^2 - x^2)(b^2 + y^2)$ is a function of a, b, x, and y. For the distinctive names of functions, see Transcendental and Algebraical.

All algebra is, in one sense, a calculus of functions; but the name is peculiarly appropriate, and always given, to that branch of investigation in which the *form* of a function is the thing sought, and not its value in any particular case, nor the conditions under which it may have a particular value. [Equations, Functional.] For instance, 'What is that function of x which, being multiplied by the same function of y, shall give the same function of $x + y$?'—is a question of the calculus of Functions.

Various isolated questions connected with this calculus have been treated, from the time of Newton downwards, particularly by Lagrange, Laplace, Monge, and Euler. But the direct solution of functional equations, or at least the first attempt to form general methods in the case of functions of a single variable, appears to have been made by Mr. Babbage and Sir J. Herschel (1810-1813). To the treatise entitled 'Examples of the Calculus of Differences,' by the latter, the former appended another, containing examples of the solutions of functional equations. This and the article, 'Calculus of Functions,' in the 'Encyclopædia Metropolitana,' are the only formal treatises on the subject, of which we know.

A function of x is denoted by ϕx, ψx, χx, fx, Fx, Φx, &c., &c., the first letter being a symbol of an operation to be performed. Thus, Ffx denotes that when the operation signified by f has been performed upon x, that signified by F is performed upon the result. When the same operation is repeated, the results may be denoted by fx, ffx, $fffx$, &c., which may be abbreviated into fx, f^2x, f^3x, &c. For different points of interest connected with the relations of functional forms, see Periodic; Inverse.

FUNCTIONS, THEORY OF, a name given by Lagrange to a view of the principles of the Differential Calculus, of which we have expressed our opinion in the article Differential Calculus. The works of Lagrange, in which its details are to be found, are 'Théorie des Fonctions Analytiques,' first edition, 1797; second edition, 1813; and 'Leçons sur le Calcul des Fonctions,' of which the first edition is volume 10 of the 'Leçons de l'Ecole Normale (1801), and the second was published in 1806.

Taking Lagrange's intention to have been the proof that algebra, as it existed in his time, was sufficient to demonstrate the principles of the Differential Calculus without the introduction of limits, we have only to remark that the end is completely attained. [Differential Calculus.] It is plain to any one acquainted with that calculus, that a demonstration of Taylor's Theorem being once attained, all the rest follows. We now proceed to look at the proof of this theorem given by Lagrange, with reference to absolut correctness or incorrectness.

Lagrange first attempts to prove that every function ϕx has this property, that $\phi(x + h)$ can be expanded in a series of the form

$$\phi(x + h) = \phi x + Ah + Bh^2 + Ch^3 + \ldots\ldots$$

He says, firstly, that no negative powers of h can enter the expansion, for if such were the case $\phi(x + 0)$, instead of being ϕx, would be infinite. This is true as to any finite number of negative powers of h, but does not exclude an infinite series of negative powers. For instance,

$$\frac{1}{x + h} = \frac{1}{h} - \frac{x}{h^2} + \frac{x^2}{h^3}$$

when $h = 0$, *all* the terms become infinite, but the first side of the equation is not infinite. Secondly, he assumes that there cannot be fractional powers of h, for if such were the case, there must be fractional powers in the original function ϕx, and if ϕx had m different values, and if $Kh^{\frac{p}{n}}$ were one of the terms of the development, the n values of this latter, combined with the m values of ϕx, would give mn different values to $\phi(x + h)$, instead of m. In answer to this it may be asked how is it known, *à priori*, that there must be a series of powers of h, *every* value of which is an expansion of $\phi(x + h)$? May it not possibly be true that there is an expression of the form

$$\phi(x + h) = \phi x + Ah^a + Bh^b$$

which is true under certain conditions, determining which of the values of the several terms are to be taken? Thirdly, he assumes that (having thus obtained a series, in which only whole powers of h are found) the supposition $h = 0$ must reduce it to its first term; an assumption which can only be admitted of such a series as $M + Ah + Bh^2 + \ldots$ when it can be made convergent by giving sufficiently small values to h.

Having once proved or assumed that $\phi(x + h)$ can be expanded in a series of the form $\phi x + Ah + Bh^2 + \ldots$ the proof of Taylor's Theorem, given by Lagrange, does not differ from the common one. He calls A the derived function of ϕx, and denotes it by $\phi' x$: generally, if changing x into $x + h$ change P into $P + P'h + \ldots$, P' is the derived function of P. The derived function of $\phi' x$, denoted by $\phi'' x$, is called the second derived function of ϕx, and so on. By changing x into $x + k$, $\phi(x + h)$, or $\phi x + Ah + Bh^2 + \ldots$, becomes

$$(\phi x + \phi' x . k + \ldots) + (A + A'k + \ldots) h + (B + B'k + \ldots) h^2 + \ldots\ .$$

and by changing h into $h + k$, $\phi(x + h)$ becomes

Public Library $+ k) + B(h + k)^2 + \ldots$

These must be the same, since both represent $\phi(x+h+k)$: and by equating the terms which contain the first powers of k, we find

$$\phi' x + A' h + B' h^2 + \ldots = A + 2Bh + \ldots.$$

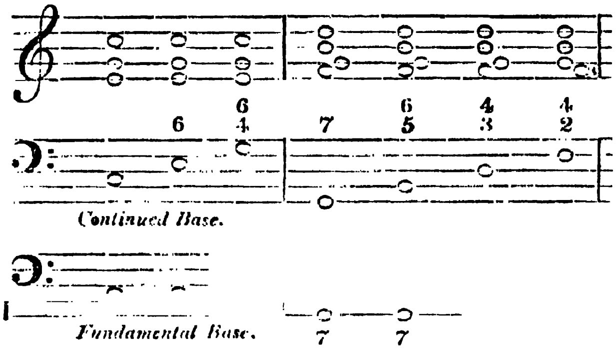
whence $A = \phi' x$, $2B = A' = \phi'' x$, and so on. The reader will recognise in this process the proof frequently given by means of the preliminary lemma, that if

$$u = \phi(x+h), \quad \text{then } \frac{du}{dx} = \frac{du}{dh}.$$

The works of Lagrange on this subject, though defective in their fundamental positions, except upon the explanation given in DIFFERENTIAL CALCULUS, yet abound in new and useful details, given with all the elegance for which his writings are distinguished: and the student will find them well worth his attention.

FUNDAMENTAL BASE, in music, is the lowest note of the Perfect Chord, or Triad, as the Germans call it, and of the chord of the 7th: hence it is the root of all real chords:—for chords not derived from either the perfect chord or that of the 7th, are considered as suspensions or retardations; or, to speak in unaffected language, the discordant notes of which they are composed are simply appogiaturas. [CHORD.]

The following will show the two *Fundamental Chords*, and their inversions, with the continued [CONTINUED], or ordinary base, and the *Fundamental Base*.



This term is not the best that might have been chosen: the same meaning is much better conveyed by the word *radical*, introduced, we believe, by Dr. Callcott. The *system* of the Fundamental Base, founded on harmonics, and a continual addition of thirds to the triad, is indebted for its origin to Rameau, the celebrated French composer [RAMEAU], and was once almost universally received. D'Alembert wrote a book to explain and eulogise it, and Marpurg, a most distinguished theorist, adopted it in his *Handbuch bey dem Generalbasse*. But though it may be rendered in some degree serviceable in the analysis of chords, it is in more than one respect erroneous, and the rules drawn from it by its author would cruelly fetter genius, were they allowed to exert any influence on the composition of music. Rameau's once vaunted system is now therefore entirely laid aside, even in the country that gave it birth.

FUNDS and FUNDING SYSTEM. [NATIONAL DEBT.]

FUNDY, BAY OF, is the most extensive gulf on the eastern coast of North America, between Cape Florida and the mouth of the St. Laurence river. It separates Nova Scotia from New Brunswick, and lies between 44° and 46° N. lat. and 63° and 67° W. long. Its direction is from east-north-east to west-south-west; its entrance is at the west-south-western extremity.

This entrance is formed by Brier Island, on the side of Nova Scotia and Quoddy Head, on the mainland; a straight line between these two points passes through the island of Grand Manan, which lies about 8 or 9 miles from Quoddy Point, and 35 miles from Brier Island. In this part the bay is about 50 miles wide; but it narrows by degrees to about 30 miles and less, after which it again attains a width of between 30 and 35 miles, which breadth it preserves for the greatest part of its extent, the shores of Nova Scotia and New Brunswick running nearly parallel. Towards its inner extremity it is divided, by a bold headland terminating with Cape Chignecto, into two smaller bays, of which one extends due east, and is called the Bay of Minas; the other, preserving the east-north-eastern direction, is named Chignecto Bay. The whole length of the Bay of Fundy is about 180 miles.

Both shores of the large bay are rocky and bold, but especially so on the side of Nova Scotia, where a chain of hills, probably not less than 500 feet above the sea, rises at a short distance from the coast. The entrances, both of the Bay of Minas and of Chignecto, are likewise rocky; but in the interior the shores are low, sandy, and flat.

The navigation of the bay is both difficult and dangerous, on account of the great strength of the tide and the prevailing fogs. The tide rises to a great height, sometimes seventy feet, and flows with great rapidity, running at the entrance about three miles an hour, increasing as it advances to more than seven, and at length rushing with great impetuosity into the bays of Minas and Chignecto. Fogs cover the bay when the wind blows from the east and south-east, or from the Atlantic; and during their prevalence many vessels are cast on the rocky shores by the violence of the tides.

The Bay of Minas has been united with Halifax Harbour, which is situated on the Atlantic side of Nova Scotia, by a canal fifty-four miles long, and capable of receiving vessels which draw only eight feet of water. It is called the Shubenacadie Canal. Another canal was projected a few years ago, which was to connect the most northern corner of Chignecto Bay, called Cumberland Basin, with Northumberland Strait. This strait separates Prince Edward Island from New Brunswick and Nova Scotia, and one of its bays, called Bay Verte, is separated from Cumberland Basin only by an isthmus eleven miles across. The advantages of such a canal are obvious; but we are not aware that it has been executed. (M'Gregor's *British America*; Bouchette's *British Dominions in North America*.)

FÜNEN, or FUHNEN (in Danish Fyen), a 'stift' or province of Denmark, consisting of the islands of Fünen, Langeland, Taasing, and several islets. It has an area of 1286 square miles, and a population of about 160,000 (in 1801, 121,378), and is divided into the two circles or bailiwicks of Odense and Svendborg, which contain 3 earldoms, 4 baronies, 9 towns, and 201 parishes. It is a bishop's see, and is subdivided into 15 minor circles or herreder, in which there are 180 seignorial estates. The soil is a layer of rich loam on a substratum of clay or sand: it has some hills, but no streams deserving the name of rivers. The produce is grain, vegetables, flax, &c., and great number of horses and cattle are reared. The whole of the town are in the island of Fünen, with the exception of Rudkiöbing, in the island of Langeland, a place of much trade, with about 250 houses and 1500 inhabitants

FÜNEN, or FYEN, an island situated in the Baltic, between the eastern coast of the duchy of Schleswig and of Jütland, and the western shores of the island of Seeland, from which parts it is separated by the Great and Little Belts, between 55° 2′ and 55° 47′ N. lat. and 9° 46′ and 10° 51′ E. long. Its area is about 1176 square miles, and its population, which was 91,333 in 1769, is at present about 144,000. The surface is a level, varied by hills in the southern districts, but they never rise above 500 feet. The north-east of the island is deeply indented with bays of the Kattegat, particularly the 'Odense fiord,' and is more uniform and less wooded than the south. The soil is in general rich and productive. Fünen abounds in small streams, here called Aas, and lakes: the most considerable lakes are those of Arreskov, Brendegards, and Juulbye. The canal of Odense, which commences at Odense and terminates at Skibhusene, on the Odense fiord, is about two miles and a half in length, ten feet deep, and fifty feet in breadth at the surface. The climate is damp and variable, but milder than that of Seeland. About 610,000 acres are arable and meadow land. The principal crops are barley, oats, and buckwheat, and the quantity of grain annually exported amounts to about 100,000 quarters. Much flax and hemp are raised, and the growth of hops exceeds 2300 cwts. yearly. With the exception of potatoes, the cultivation of vegetables is limited, but the orchards are numerous, and an inferior kind of cider is made. About 78,600 acres are occupied by woods and forests, which, with the peat-moors, supply fuel. The Fünen breed of horses is much sought after, and the stock of the island, including that of Langeland, is upwards of 42,000: that of horned cattle is about

81,000, and of sheep, mostly of improved breeds, 90,000. It is estimated that upwards of 20,000 swine are fed. Honey and wax are regular articles of exportation. There is no game besides hares and rabbits, but a great quantity of wild-fowl and poultry, especially geese. The fisheries are productive. The only minerals are freestone, chalk, and limestone. There are no manufacturing establishments; the peasantry however are industrious operatives under their own roofs, and make their own woollen and linen yarn, stockings, and clothing. The townspeople prepare leather and manufacture brandy. Gloves are made at Odense, and woollens and linens are printed at Svendborg.

The exports of Fünen consist of corn, pease, brandy, apples, horses, oxen, butter, salted meat, tallow, hides, hops, linen, honey, and wax. Odense, which by its canal has a direct access to the sea, is the great trading mart of the island. There is a good road from Middelfahrt to this town; but the roads are in general very bad. The people of Fünen are, like their neighbours, somewhat indolent and shy of work, as well as phlegmatic: they are however an honest, sound-hearted race. Their religion is the Lutheran.

The principal towns in Fünen are Odense, the capital and episcopal residence, pleasantly situated, and reputed to be the most antient town in Denmark; in 55° 25′ N. lat., and 10° 22′ E. long. It has about 1100 houses, and 8600 inhabitants. Here are a royal palace, built by Frederick IV., a townhall, four churches (of which that of St. Canute is a noble Gothic pile, erected eight centuries ago, and containing the mausolea of St. Canute, Erichslaf, John, and Christian III., kings of Denmark and Norway), a chapter seminary, gymnasium, theatre, two public libraries, hospital, house of correction, &c. Assens, on the western coast, at the entrance into the Little Belt, another old town, has an indifferent harbour, a townhall, one church, about 350 houses, and 2330 inhabitants. Bogense, on the north coast, the smallest town in the province, has one church, about 250 houses, and 1000 inhabitants. Kiertеminde, beautifully situated on a bight of the Great Belt, which is crossed by a large wooden bridge, has one church, a school, two hospitals, about 260 houses, and 1500 inhabitants. Middelfahrt, on the Little Belt, has a townhall, church, hospital, school, about 240 houses, and 1300 inhabitants, and a ferry about a mile across to Snoghoi on the Jutland coast. Svendborg, the chief town of the bailiwick of this name, is at the south-eastern extremity of Fünen, on an arm of the Baltic which separates that island from Taasing; in 55° 5′ N. lat. and 10° 38′ E. long. It has two churches, a townhall, three schools, about 350 houses, and 3400 inhabitants, and exports much grain, &c. Nyeborg, a fortified town on the eastern coast, contains the remains of the palace in which the kings of Denmark held their courts and national diets, with a church, townhall, several schools, a hospital and an infirmary, about 300 houses, and 2900 inhabitants. The Swedes were totally defeated by the Danes under its walls in 1659. And lastly, Faaborg, in the south-west, is a small town with about 260 houses and 1500 inhabitants, a handsome church, &c., and a good harbour on an arm of the Little Belt, protected at its entrance by the three islands of Lyöe, Avernaröe, and Biörnöe.

FUNERAL, the performance of the rites of sepulture or burial; generally supposed to be derived from the Latin *funis*, a torch, because, at least in the Roman times, funerals were sometimes performed by torch-light. Others derive the word from *phónos* (φόνος), 'slaughter,' as designating death.

The Egyptians are among the earliest people of whose religious ceremonies we have authentic accounts, more particularly in what related to their dead. Upon this occasion the parents and friends of the deceased put on mourning habits, and abstained from gaiety and entertainments. The mourning lasted from forty to seventy days, during which time the body was embalmed; and, when the process was completed, placed in a sort of chest, which was afterwards preserved either in their houses or in the sepulchres of their ancestors. Before the dead were allowed to be deposited in a tomb, they underwent a solemn judgment, upon an unfavourable issue of which they were deprived of the rite of burial.

The mourning customs of the antient Jews can only be collected from an examination of the Prophets and other parts of Scripture. That they sometimes burnt the body is clear, but burial in a sepulchre was the more general fashion. The circumstances attending the burial of the dead among the modern Jews are minutely detailed by D. Levi, in his 'Succinct Account' of their Rites and Ceremonies, p. 162-170.

The funeral rites of the Greeks and Romans have been collected with great research by Guichard in his 'Funérailles, et diverses Manières d'ensevelir des Romains, Grecs, et autres Nations,' 4to., Lyon, 1581; by Meursius, in his treatise 'De Funere Græcorum et Romanorum,' 12mo., Hag. Com. 1604; by Gutherius, 'De Jure Manium, seu de Ritu, More, et Legibus prisci Funeris,' 12mo., Par., 1613, reprinted in 4to., 1615, and again in 8vo., Lips., 1671; and by Kirchman, 'De Funeribus Romanorum Libri IV.,' 12mo., Hamb., 1605, and Lugd. Bat., 1672. See also the 'Ceremonies Funèbres de toutes Nations,' par le Sr. Maret, 12mo., Par., 1677.

In the religious creed both of the Greeks and Romans, sepulture was peculiarly an act of piety toward the dead, without which it was supposed the departed spirit could not reach a place of rest. To be deprived of the proper rites was considered the greatest misfortune. The funeral rites of the Greeks and Romans were in many respects similar, and among both nations the practice prevailed of burning the dead and collecting the ashes in urns. In the case of public funerals, according to Servius's Commentary on Virgil, the deceased was kept seven or eight days, and every day washed with hot water, or sometimes with oil, that in case he were only in a slumber he might be waked; and at stated intervals his friends meeting made a shout with the same view: this was called *conclamatio*. On the seventh day, if no signs of life appeared, he was dressed and placed on a couch in the vestibule, with the feet outwards, as if about to take his departure. In the course of these seven days, an altar was raised near the bed-side, called *acerra*, on which the friends offered incense. The scene here described is frequently represented in antient bas-reliefs. (See the *Townley Marbles*, vol. ii., pp. 167, 228, &c.) On the seventh day the last 'conclamatio' ended, when the couch and body were carried to the *rostra*, where the nearest of kin pronounced the funeral oration, and afterwards to the funeral pile. The body having been consumed, the ashes were gathered, inclosed in an urn, and finally laid in the sepulchre or tomb. An apotheosis or canonization was frequently part of the funeral ceremony of the emperor.

The Magi among the Medes and Persians neither burned nor buried their dead, but left them to birds of prey or dogs. (Herod. i., 140; Strabo, 735, 746.) Chardin, in his 'Travels,' vol. ii., p. 186, has given a full description of a modern Persian cemetery; and Niebuhr describes the Parsees near Bombay as still exposing their dead after the antient fashion mentioned in Herodotus. (Niebuhr, *Reisebeschreibung*, ii., 50.) Tacitus, in his treatise 'De Moribus Germanorum,' (c. 27) notices the simplicity of the funerals among the antient Germans. Like the Romans, they burned their dead. The things which a German valued most were his arms and his horse: these were added to the funeral pile, with a persuasion that the deceased would have the same pursuits in his new state of existence.

In the tomb of Childeric, king of the Franks, his spear, his sword, with his other warlike weapons, and even his horse's head, were found. (See Montfaucon, *Monumens de la Monarchie Françoise*, tom. i., p. 10.)

Lafitau, Charlevoix, and other travellers describe the same notions of a future state and the same funeral ceremonies as prevalent among the savages of America. Dr. Robertson (*Hist. of Amer.*, vol. ii., b. 4) says, as they imagine that departed spirits begin their career anew in the world whither they are gone, they bury together with the bodies of the dead, their bow, their arrows, and other weapons used in hunting or war; they deposit in their tomb the skins or stuffs of which they make garments, Indian corn, venison, domestic utensils, and whatever is reckoned among the necessaries in their simple mode of life.

For the funeral rites of the early Christians, the reader may consult Gretser 'De Funere Christiano,' 4to., Ingolst., 1611; and he may learn the customs of a later period from Durand, who wrote his 'Rationale Divinorum Officiorum' in the twelfth century.

Brand, in his 'Popular Antiquities,' vol. ii., p. 139 to 212, has much upon the English ceremonials, beginning with

'Watching with the Dead,' called in the north of England the Lake-Wake; he then proceeds with 'Laying out or streaking the Body;' setting salt or candles upon it; funeral entertainments; sin-eaters; mortuaries; following the corpse to the grave, and carrying evergreens, torches and lights at funerals; black used in mourning; the pall and under-bearers; doles and donations to the poor at funerals church-yards; garlands in churches; and strewing flowers upon graves.

Strutt's 'Manners and Customs,' and Gough's 'Sepulchral Monuments of Great Britain,' are other works to which the reader may refer for the antient funeral rites of England.

Funeral entertainments, called silicernia and *cœnæ ferales* by the Romans, are of very antient date. They are still kept up in the north of England, and are there called arvals or arvils. Among some extracts from the Berkeley Manuscripts, we read that 'From the death of Maurice, the fourth Lord Berkeley, which happened June 8th, 1368 until his interment, the reeve of his manor of Hinton spent three quarters and seven bushels of beans in fatting one hundred geese towards his funeral, and divers other reeves of manors the like, in geese, ducks, and other poultry. Walsingham, speaking of those who attended Richard II.'s funeral at Langley, in 1399, says, 'Nec erat qui eos invitaret ad prandium post laborem.' (*Hist.*, p. 405.) Shakspeare has a well-known allusion to these feasts in Hamlet act i., sc. 2:

> 'The funeral baked meats
> Did coldly furnish forth the marriage tables.'

FUNERAL ORATIONS, discourses at funerals, are of great antiquity. The second book of Thucydides (c. 35 &c.) contains the laboured harangue delivered by Pericles at the solemn funeral ceremony instituted in honour of those Athenians who fell at the beginning of the Peloponnesian war; and other similar orations are extant in Greek Augustus, at the early age of twelve, performed this office for his grandmother, and afterwards, when emperor, for the young Marcellus. Tacitus tells us that Nero pronounced a funeral oration over his wife Poppæa. Funeral orations were equally common over Christian martyrs; and Durand. in his 'Rationale,' already referred to, says, 'Ceterum priusquam corpus humo injecta contegatur, defunctus oratione funebri laudabatur.' Fuller, in his 'Appeal of injured Innocence,' (part iii., p. 75,) and Misson, in his 'Travels in England,' show the continuance of this practice to the close of the seventeenth century. Gay alludes to it in his 'Dirge:'

> 'Twenty good shillings in a rag I laid.
> Be *ten* the parson's for his sermon paid.'

The practice of delivering what may be properly called funeral orations, that is, addresses over the grave or at the interment of the dead by laymen, is common among the French, and is not unfrequent on great occasions among the people of the United States.

FUNERAL SHOWS or GAMES frequently followed public funerals among the Greeks and Romans. An early example of this occurs in the funeral games celebrated by Achilles in honour of Patroclus. (Homer, *Iliad.*) As the dead were supposed to be delighted with blood, various animals, especially such as the deceased had been fond of, were slaughtered at the pile, and thrown into it: and, in still ruder times, captives or slaves. Among the Romans, gladiators, called *bustuarii*, were made to fight. Junius Brutus exhibited gladiators at his father's funeral; and the 'Adelphi' of Terence, at a later period, was produced for the first time at the funeral of Lucius Æmilius Paulus.

FÜNFKIRCHEN (in Hungarian *Pecs*, and in the national records Quinque Ecclesiæ), an old town in the county of Baranya in Hungary, and the seat of provincial administration, consists of a single street built at the foot of the lofty Mount Metshek, and at the edge of a rich and extensive valley, in 46° 5′ N. lat. and 18° 16′ E. long. Soyman, the Turkish sultan, who resided here, was wont to call it 'the Paradise of the Earth.' The number of houses is about 2000, and the population is about 11,500. This town contains several handsome buildings, an episcopal palace, an ecclesiastical seminary, a gymnasium, a cathedral standing on high ground (the site of a Roman castellum), and said to be the oldest in Hungary, a fine, massively-built church of the Jesuits, several churches, some of which were formerly Turkish mosques, a public library and cabinet of coins, two monasteries, two hospitals, &c. In the vicinity are mines of excellent coal, and some alum and vitriol works, as well as extensive vineyards. Large quantities of grain and tobacco are grown about Fünfkirchen, and much rape-seed is raised for making oil. The trade of the town is chiefly in the produce of the country, and in leather, which is manufactured here, and in great request throughout Hungary. There are mineral springs and baths. Some have supposed that the Roman colony Serbinum was planted on this spot. It was in the hands of the Turks from 1543 to 1686, and is the place of assembly for the provincial states.

FUNGI. Under this name botanists comprehend not only the various races of mushrooms, toadstools, and similar productions, but a large number of microscopic plants forming the appearances called mouldiness, mildew, smut, rust, brand, dry-rot, &c. Notice has been occasionally taken of these plants under their respective heads; in this place some general account will be given of them as a large natural order.

Nothing can well be more different than the extremes of development of Fungi, if the highest and the lowest forms are contrasted; as for example, the large fleshy Boleti, which inhabit the trunks of trees, and the microscopic mould-plants, composed of threads much too delicate to be distinguished by the naked eye. Nevertheless, it turns out upon inquiry that the latter is only a simple form of the former, or, in other words, that a Boletus is merely an enormous aggregation of the vegetable tissue constituting a Mucor, developed upon the same plan, subject to the same influences, possessing a similar chemical character, and propagating by means which are altogether analogous.

Viewed with reference to their whole extent, the plants of this order may be described as cellular or filamentous bodies, having a concentric mode of development, often when full grown almost amorphous, absorbing oxygen and exhaling carbonic acid, and propagating either by means of microscopic granules, which are lodged in particular receptacles, or by a dissolution of their whole tissue.

That they are cellular or filamentous may be easily ascertained by examining them with even an indifferent microscope; perhaps they might be even simply described as cellular, for their filamentous tissue seems nothing but cells drawn out. Sometimes, as in the genus Uredo, they consist of spheroidal cells, having little connection with each other, each cell containing propagating matter, and all separating from each other in the form of a fine powder when ripe: the smut in corn is of this nature; or, as in Cylindrosporium, the cells are truncated cylinders not adhering, so far as we can see, and separating in like manner when ripe. In plants of a more advanced organization, as the genus Monilia, the constituent cells are connected in series, which preserve their spherical form, and also contain their own reproductive matter; while in such plants as Aspergillus the cells partly combine into threads forming a stem, and partly preserve their spheroidal form for the fructification (*fig.* 24). From adhering in simple series, the structure of Fungi advances to a combination of such series into strata, whence result the various kinds of dry-rot, thick leathery expansions developing amidst decaying timber; a more complicated form is thence produced in the form of puff-balls, truffles, sclerotiums, and the like, in which a figure approaching that of a sphere is the result, the reproductive cells being indiscriminately confused in the interior of such plants; and finally, the organization is so much complicated, that, independently of a mere aggregation of tissue, we find envelopes of various kinds for the protection of the propagating mass, as in Agaricus and Geastrum, and special receptacles for the propagating matter, as in Boletus and numerous others.

It is probable however that in all Fungi, and certain that in most of them, the first development of the plant consists in what we here call a filamentous matter, which radiates from the centre formed by the spore (or seed), and that all the cellular spheroidal appearances are subsequently developed, more especially with a view to the dispersion of the species. We purposely say dispersion, not multiplication; for it is certain that the filamentous matter is quite as capable of multiplying a fungus as the cellular or spheroidal. This is partly proved by the common mushroom (Agaricus campestris), whose filamentous matter is commonly sold, under the name of spawn, for the artificial multiplication of that species in gardens; and more completely by some recent experiments of M. Audouin, who found that the

Botrytis Bassiana would inoculate caterpillars and other larvæ as readily by minute portions of its spawn as by its spores or seedlike spheroidal particles. Although, however, there seems so much reason to ascribe the presence of a filamentous spawn to all Fungi, yet it is seldom seen by the ordinary observer; for it develops out of sight, under ground, in the midst of the decaying matter on which Fungi so often appear, or through the very substance of living matter; and it is only the aggregation of spheroidal matter which we see. It would appear that for the growth of the former darkness is necessary, and that the latter is stimulated into existence by the action of a feeble quantity of light. To apply to these parts familiar and equivalent names, we should say that the stalk or stem radiates in dark damp situations, where it is buried from sight, and that the spheroidal part or fructification alone is able to develop beneath the light of day. The spawn of the mushroom is its stem, the mushroom itself is the fructification of the plant.

It is generally believed that spiral cells are unknown in Fungi; Corda however, in his recent microscopical work on these plants (*Icones Fungorum hucusque cognitorum*, Prag. 1837), figures them in the genus Trichia, calling them elaters, and thus assigning them a nature analogous to that of the organs known by the same name in Jungermanniaceæ and Marchantiaceæ.

The concentric growth of the filamentous stem or spawn of Fungi may generally be witnessed in damp cellars, when they begin to grow without impediment upon the walls or decaying wood. Nothing is more common in such situations than to see a beautiful white flocculent matter, which a breath almost will dissipate, spreading from a centre nearly equally in all directions; such appearances, formerly called byssi, have been ascertained to be the spawn of various kinds of Fungi, the fructification of which is probably never developed. Evidence of the existence of a similar mode of growth may be found when the spawn itself is not visible, as in fields where Fungi so often spring up in circles or rings; this arises from their stem having originally spread circularly from its point of origin, and thrown up its fructification at the circumference of the circle so formed.

Unlike other plants, Fungi, instead of purifying the air by robbing it of its carbonic acid and restoring the oxygen, vitiate it by exhaling carbonic acid and absorbing oxygen. This has been proved experimentally by Dr. Marcet of Geneva; and (Lindley, *Intr. Bot.*, ed. 2, p. 324) will probably explain the cause of Fungi being so universally destitute of green colouring matter, which we know results from the decomposition of carbonic acid. It affords, no doubt, an additional argument to those who believe that Fungi are an intermediate kingdom between plants and animals; an idea which, like that of believing them to be 'atoms of vegetable matter combined by the expiring forces of nature,' we do not think it necessary seriously to discuss. That they are not equivocally generated is sufficiently proved by each species having its own particular kind of seed or spore: a provision that would be perfectly unnecessary if the species sprang up out of decaying matter by the mere action of particular combinations of external forces. To assert the existence of fortuitous creations in this class of plants is contrary not only to analogy but to the plainest evidence. The experimental observer may indeed discover that Fungi will regularly develop in one kind of chemical mixture and not in another: Dutrochet, for example, found that, if he acidulated a weak solution of white of egg, different species of Monilia rapidly formed upon it; while, if he rendered such a solution slightly alkaline, the genus Botrytis made its appearance, and that the solution in its simple state, neither alkalescent nor acidulated, produced no Fungi—a remarkable circumstance enough. But it would be too much to infer from such an experiment, 'that invisible germs of a filamentous plant may be created by the chemical action of an acid or an alkali on organic matter dissolved in water, and that they develop by virtue of the vital action which would be the necessary attribute of this *chemico-organic molecular compound*:' on the contrary, the experiment only showed that the seeds of Fungi, like those of other plants, require special soils in which to grow; that Botrytis will not grow in acid mucilage, nor Monilia in alkaline, nor either in mucilage in a neuter state. This is only what happens in plants of a more highly organized nature. Who ever saw the horned poppy of the sea-shore growing spontaneously in an inland field, the marsh marigold on a dry heath, or the reindeer lichen of Lapland on a heath in Italy? Let any one take a few different kinds of seeds and commit them all to the ground in the same place; some will spring up and flourish, others will just appear above ground and then perish, others will make an attempt to germinate. This, an every-day event, is a sufficient explanation of the fact elicited by M. Dutrochet's experiment. Every kind of seed has something specific in its nature, in consequence of which it requires particular kinds of soil, and some special combination of heat, light and moisture, to be roused into a state of vegetation. As to the presence of the seeds of the Botrytis and Monilia in the vessels in which M. Dutrochet's experiments were conducted, it is perfectly easy to conceive that the seeds of such common plants exist everywhere suspended in the air or adhering to the cleanest vessels; they are so numerous as to baffle all powers of calculation; they are so minute as only to become visible when aggregated in masses of many thousands, and so generally dispersed that it is difficult to conceive a place in which they may not be reasonably supposed to exist. The very general existence of dry-rot is no weak evidence of this; but upon that subject we have already made what observations we have thought necessary. [Dry-Rot.]

Fungi are among the most numerous of all plants in regard to genera and species, so abundant indeed that no one has as yet attempted to form an estimate of their numbers. Fries somewhere asserts that he had discovered above 2000 within the compass of a square furlong in Sweden; even the European species of microscopic Fungi are but little known, if we are to judge from the numerous new kinds introduced into Corda's recent work; and as for those which inhabit the tropics, our knowledge of them amounts to little or nothing. It is generally asserted that they are uncommon in tropical countries, but it is doubtful whether this is true, and at all events it appears from the evidence of a recent traveller in that island that they are extremely abundant in Java.

They usually prefer damp, dark, unventilated places, such as cellars, vaults, the parts beneath decaying bark, the hollows of trees, the denser parts of woods and forests, or any decaying matter placed in a damp and shaded situation; and are most especially averse to dryness and bright light. Even when they appear upon the live leaves of trees, the stems of corn, or in similar situations, it is either at the damp and wet season of the year, late in the autumn, or in damp and shaded places; and M. Audouin has shown experimentally that when live insects are attacked by them it is only when they are confined in damp unventilated places. (See *Comptes rendus*, 2nd half-year, 1837.) In stations favourable to their multiplication they often commit extensive ravages, attacking and destroying timber, and producing decay in all kinds of vegetable matter of a soft and succulent nature; nor is it to dead matter that their ravages are confined. They sometimes fix themselves upon live insects, producing great havoc among the silkworms in the manufactories of Italy, and are probably the cause of a more extensive destruction of such animals than we at present have any idea of. Under the name of mildew and blight they commit excessive damage among living plants, as the farmer and orchardist know too well to their cost.

The systematical arrangement of these plants has long exercised the ingenuity of botanists, who have contrived various schemes of classifying them according to what are believed to be their natural relations. The most celebrated of them is the mycological system of Fries. We cannot enter at any length into the details of this arrangement; but, as some difficulty attends the study of it, a short explanation of its fundamental principles may be useful. We shall therefore give a brief explanation of the leading features of this author's arrangement.

Fries in the first place divides the whole order into four Cohorts, distinguished by the following characters:—

Cohort I. Hymenomycetes. A Hymenium present; that is, the fungus opened out into a fructifying membrane, in which the spores (seeds) are placed, usually in the inside of asci (transparent simple cases). The texture wholly filamentous.

Cohort II. Pyrenomycetes. A Perithecium present; that is, the fungus closed up: then perforated by a hole or irregular laceration, and enclosing a distinct kernel holding asci. Texture obscurely cellular; that of the stroma (receptacle) somewhat filamentous.

Cohort III. Gasteromycetes. A Peridium present; that is, the fungus at first closed up and containing loose spores, having no asci. The texture cellular.

Cohort IV. Coniomycetes. Spores naked; that is, the fungus in its elementary state, eventually having the spores quite naked, although they may have been covered at first. The texture between filamentous and cellular; and the thallus often apparently absent.

He then subdivides these cohorts each into four Orders, as follows:—

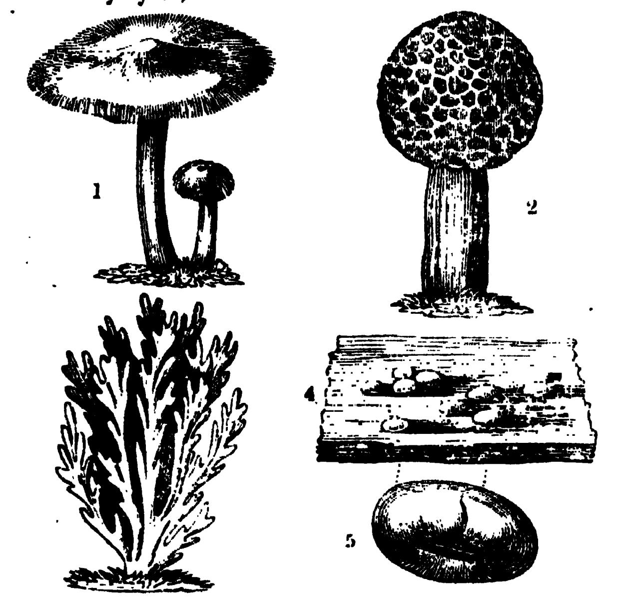
Cohort I.—Hymenomycetes.

Order 1. *Pileati*. The Hymenium on the under side and having asci (*fig*. 1, Agaricus).

Order 2. *Elvellacei*. The Hymenium on the upper side, and having asci (*fig*. 2, Morchella).

Order 3. *Clavati*. The Hymenium on both sides and having asci (*fig*. 3, Clavaria).

Order 4. *Tremellini*. Amorphous. The Hymenium confounded with the receptacle. Asci none. Membranous or gelatinous, with a filamentous texture (*figs*. 4, 5, Dacrymyces).



Hymenomycetous Fungi.
1. Agaricusodorus, reduced in size; 2, Morchella esculenta, reduced in size; 3, Clavaria cinerea, reduced in size; 4, Dacrymyces stillatus, growing in wood, natural size; 5, the same, magnified.

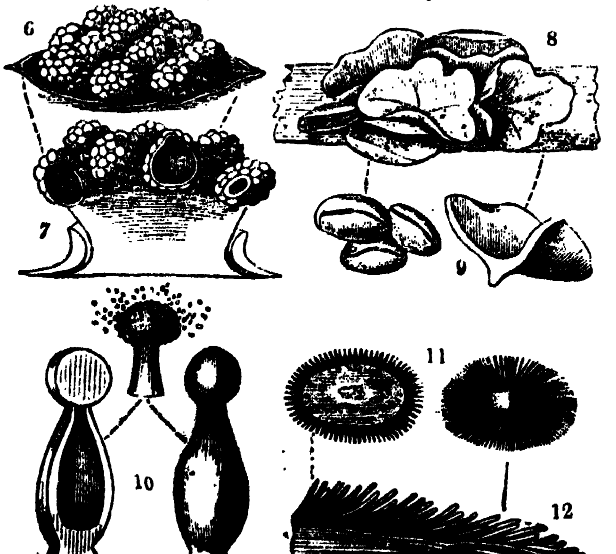
Cohort II.—Pyrenomycetes.

Order 1. *Sphæriacei*. The kernel filled with asci, and deliquescent (*figs*. 6, 7, Cucurbitaria).

Order 2. *Phacidiacei*. The kernel filled with asci, and dry (*figs*. 8, 9, Cenangium).

Order 3. *Cytisporei*. The kernel filled with naked spore-cases, and disintegrating (*fig*. 10, Sphæronema).

Order 4. *Xylomacei*. The kernel filled with naked spore-cases, and dry (*figs*. 11, 12, Actinothyrium).



Pyrenomycetous Fungi.
6, Cucurbitaria cinnabarina, magnified; 7, a section of the same; 8 and 9, Cenangium ferruginosum, magnified; 10, Sphæronema subulatum, magnified; 11, 12, Actinothyrium graminis, magnified.

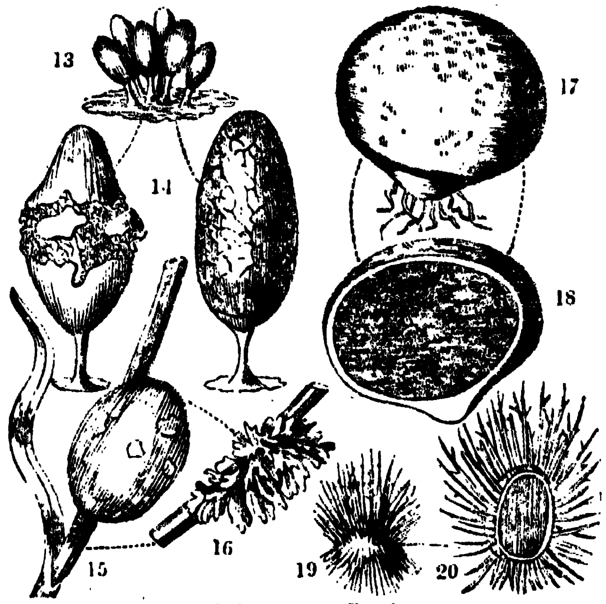
Cohort III.—Gasteromycetes.

Order 1. *Angiogastres*. Spore-cases immersed in a receptacle distinct from the peridium.

Order 2. *Trichospermi*. Spore-cases naked, among filaments distinct from the peridium (*figs*. 17, 18, Scleroderma; *fig*. 13, 14, Arcyria).

Order 3. *Trichodermacei*. Spore-cases naked, covered by filaments constituting a peridium (*figs*. 15, 16, Spumaria).

Order 4. *Sclerotiacei*. Spore-cases immersed in a receptacle constituting the peridium (*figs*. 19, 20, Chætomium).



Gasteromycetous Fungi.
13 and 14, Arcyria punicea, magnified; 15, 16, Spumaria mucilago, magnified; 17, 18, Scleroderma Cepa, magnified; 19, 20, Chætomium elatum, magnified.

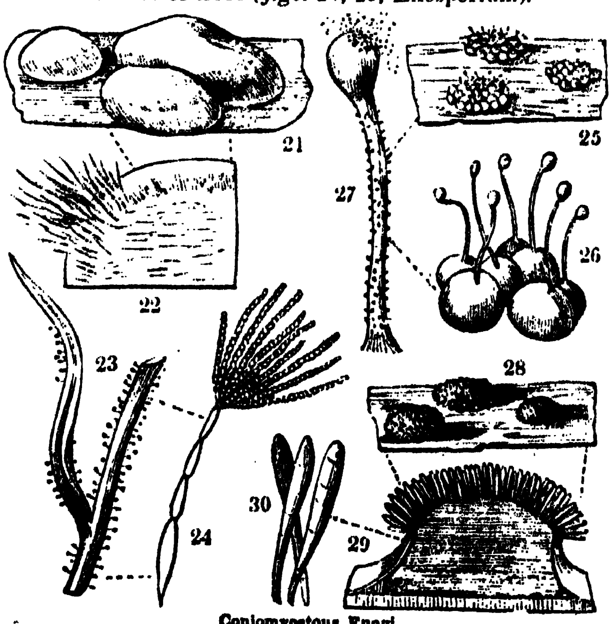
Cohort IV.—Coniomycetes.

Order 1. *Tuberculurini*. Spore-cases plunged in an entangled receptacle, upon a free receptacle (*figs*. 21, 22, Fusarium).

Order 2. *Mucorini*. Spore-cases upon a filamentous receptacle, at first enclosed in a little peridium (*figs*. 25, 26, Stilbum).

Order 3. *Mucedines*. Spore-cases at first concealed by filaments (*figs*. 23, 24, Aspergillus).

Order 4. *Hypodermi*. Spore-cases springing from under the cuticle of trees (*figs*. 28, 29, Exosporium).



Coniomycetous Fungi.
21, 22, Fusarium tremelloides, magnified; 23, a stem of grass covered with Aspergillus penicillatus; 24, the fungus itself, magnified; 25, Stilbum tomentosum, growing on a piece of wood; 26, a highly magnified representation of the same; 27, a spore-case; 28, Exosporium Tiliæ, growing on a leaf; 29, a section of the same magnified; 30, three of the spore-cases, still more magnified.

Those who wish to become acquainted with this subject practically and in its details should consult, not any, but all of the following works:—Fries's *Systema Mycologicum*; Greville's *Cryptogamic Flora*; *Neues System der Pilze*; Corda's *Icones*; Endlichar's *Genera Plantarum*; and the last part of Hooker's *British Flora*. Sowerby's *Fungi* and Bulliard's *Figures* are standard works of reference for figures of these plants.

FU'NGIA. [MADREPHYLLICEA.]

FUNGIC ACID, an acid discovered by Braconnot in the juice of most Fungi. This acid exists partly in a free state in the *periza nigra*, and combined with potash in the *boletus juglandis*; it may be obtained from the juice of either of these vegetables by evaporating it to the consistence of a syrup, and treating it with alcohol. The portion insoluble in alcohol is the fungate of potash, which is to be decomposed by acetate of lead; the fungate of lead is to be decomposed by dilute sulphuric acid, or by hydrosulphuric acid, by which the lead is separated in the state of sulphate or sulphuret, and the fungic acid is left in solution.

This acid, when pure, is colourless, very sour, uncrystallizable, and deliquescent; with lime it forms a difficultly soluble salt, and with potash and soda deliquescent uncrystallizable salts; in these and some other properties it resembles impure malic acid. Some doubt exists as to whether it is a distinct acid.

FUNGIN, the name given by Braconnot to the fleshy substance of mushrooms, purified by digestion in a hot weak solution of alkali: it is whitish, soft, insipid, and but little elastic. It is not acted upon by water, alcohol, æther, dilute sulphuric acid, potash, or soda; it is dissolved by hydrochloric acid when heated, and it decomposes and is decomposed by nitric acid; the results are much gas, oxalic acid, a bitter yellow matter, and two fatty substances, one of which resembles wax, and the other suet; the latter is most abundant. It is a highly nutritious substance, and in many of its properties it strongly resembles lignin.

FUNICULAR CURVE. [CATENARY.]

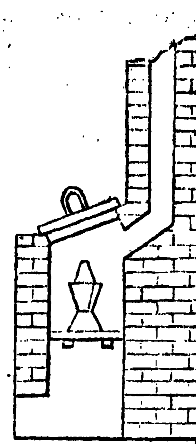
FUNNEL, a hollow conical vessel with a small pipe issuing from its apex; it is an instrument much used in common and domestic life for conveying fluids into vessels of small apertures, and in chemical operations it is used not only for this purpose but for the important one of filtering. [FILTER.] For the mere purpose of the transfer from one vessel to another of such fluids as do not act upon metals, funnels are commonly made of copper, pewter, or tin plate, and this is especially the case when they are employed for conveying powders into bottles. When however they are employed by the chemist with acid, alkaline, or such other solutions as dissolve or corrode the metals, then funnels are made of earthen or stone ware, or of glass. When used for filtration, especially in smaller and nicer operations, those of glass are always to be preferred, and of that kind called *ribbed* funnels, which, on account of the channels that their construction admits of between the filter and the funnel, allow of the more ready passage of the filtered fluid.

FURIES. [EUMENIDES.]

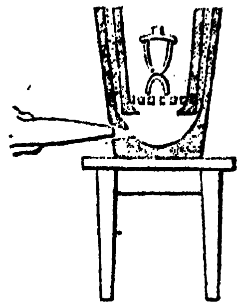
FURLONG. [MEASURES.]

FURNACE. The common grate is the most familiar example of a furnace. It is constructed of iron, and of various forms. The fuel is kept in it only by bars, in order to throw the heat out into the room. Indeed this is its principal use; and although its heat is barely sufficient to melt thin plate silver, yet many chemical operations may be performed in the common stove, and its flat sides or cheeks furnish a lower degree of heat, on which evaporation and digestion may be effected.

For the smaller operations in chemistry a great variety of furnaces have been invented: these it would be quite useless to describe. We shall therefore mention only a few of the more important and generally employed. The annexed figure represents a *wind furnace*: in this a very high temperature is produced without the use of bellows, by means of a powerful draught. The chimney of a wind furnace should be narrow and high; the furnace, represented as connected with and projecting from the chimney, should be of such a height as to allow the operator to look into it; it should be from 12 to 15 inches square, and furnished with moveable bars and a cover; every part exposed to the fire should be constructed of the most refractory bricks. When a very strong heat is required the air should be conveyed by pipes directly from without-door to the ash-pit.



Wind Furnace.



Blast Furnace.

In the figure a crucible is represented as placed in the furnace, and its cover is on.

This furnace is much employed in the reduction of metals, and in the assaying of copper and various other ores. The fuel used is either coke or a mixture of coke and charcoal.

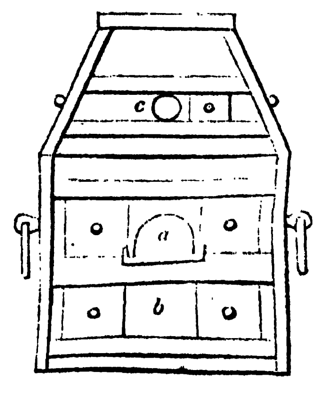
The above cut represents the *blast furnace* which Mr Faraday states in his *Chemical Manipulation* to have been for some years in use in the laboratory of the Royal Institution.

The exterior consists of a blue pot eighteen inches in height and thirteen inches in external diameter at the top. A small blue pot, of seven and a half inches internal diameter at the top, had the lower part cut off, so as to leave an aperture of five inches. This, when put into the larger pot, rested upon its lower external edge, the tops of the two being level. The interval between them, which gradually increased from the lower to the upper part, was filled with pulverized glass-blowers' pots, to which water enough had been added to moisten the powder, which was pressed down by sticks, so as to make the whole a compact mass. A round grate was then dropped into the furnace, of such a size that it rested an inch above the lower edge of the inner pot: the space beneath it therefore constituted the air-chamber, and the part above it the body of the furnace. The former is $7\frac{1}{2}$ inches from the grate to the bottom, and the latter $7\frac{1}{2}$ inches from the grate to the top; a horizontal hole, conical in form, and $1\frac{1}{2}$ inch in diameter on the exterior, was cut through the outer pot, forming an opening into the air-chamber at the lower part, its use being to receive the nozzle of the bellows. Care must be taken that the furnace is perfectly dry before it is used.

The fuel employed is coke, and the furnace is used with a pair of double bellows mounted on an iron frame, the furnace being raised upon an iron stool so as to bring the aperture of the air-chamber to a level with the nozzle of the bellows.

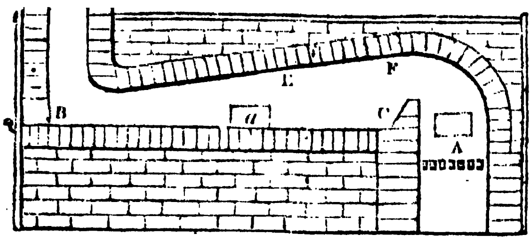
This furnace is sufficiently powerful to melt pure iron in a crucible in 12 or 15 minutes, the fire having been previously lighted. It will effect the fusion of rhodium, and even pieces of pure platinum have sunk together into one button in a crucible heated by it; all kinds of crucibles, including the Cornish and the Hessian, soften, fuse, and become frothy in it.

The *assay* or *cupelling furnace* is a small furnace made of iron, lined with refractory clay, and containing a muffle

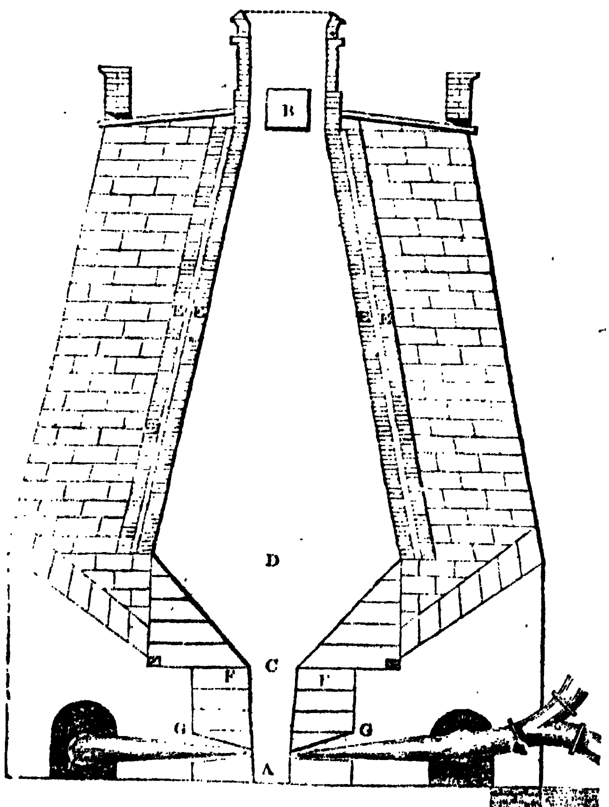


[MUFFLE]; it is used principally for the cupellation of gold and silver, which is placed upon a cupel in the muffle, previously heated to redness. The interior of the furnace contains merely the muffle resting upon two bars of iron; it is put about two-thirds into the furnace, and there is consequently left a space between it and the back part of the furnace: *a* is the orifice of the muffle, which may be closed by iron slides placed at the side. The opening *b*, placed below the grate, and which is also provided with slides, serves as well as the upper opening *c* to regulate the draught. Charcoal is used in this furnace.

For metallurgic operations on the large scale, as well as in making alkalis, red lead, &c., the *reverberatory furnace* is much used. This is shown in the annexed figure.



A is the space furnished with a grate or bars, to contain the combustible, which is either coke, coal, or wood, according to circumstances; B E F is the part on which the flame acts, E F is the roof, B C the hearth on which the substance to be heated is placed, and this is either horizontal or inclined; lastly, C is a low wall or the *bridge of the furnace*, which retains the fuel in its place, and serves to direct the flame towards the roof: *a* shows the opening of the furnace, usually placed at its side; through this the substance to be heated is introduced, and it is afterwards closed; often also there is an opening at B, to allow of a melted metal to flow out. H is a very high chimney that produces the draught, and which may be closed by a damper. As this furnace is employed for a vast number of purposes, it is evident that various forms must be used; these however it will not be necessary to describe.



Coke Pig-Iron Furnace.

The *coke pig-iron furnace* (see preceding figure) is that used in South Wales in the making of pig-iron; the height of this furnace, from the bottom at A to the filling-place at B, is 50 feet; the height of the hearth, from A to C, 8½ feet; from C to the top of the boshes at D, 8½ feet. The diameter of the hearth from A to C increases from 3 feet to 3½ feet. The extreme width at the top of the boshes D is 11 feet. The diameter of the charging-place B is 6 feet.

E E E E, the lining, is composed of a double circle of fire-bricks, about 15 inches long each, with a space for an intermediate packing of sand. F F, the hearth, is constructed of large blocks of breccia, or plum-pudding stone; G G are the twyres, or openings by which the blast is discharged into the furnace from the blowing cylinder, which is worked by a steam-engine. The contents of this furnace are 5015 feet; and it is capable of producing 100 tons of pig-iron weekly.

FURNA'RIUS. [CREEPER, vol. viii. p. 148.]

FURNEAUX'S ISLANDS. [BASS'S STRAITS.]

FURNES, or VEURNE, a small town in West Flanders, within three miles of the sea-coast, between Nieuport and Dunkerque, in 51° 5′ N. lat., and 2° 42′ E. long., 12 miles east from Dunkerque, and 26 south-west from Bruges. The town was anticntly close to the sea, but having been destroyed by the Normans it was rebuilt on its present site by Baldwin, surnamed Iron-arm. A battle was fought on the plains of Furnes in 1297, between Count Robert of Artois, commanding the troops of Philip the Fair, and Count Guy of Flanders, who commanded for Edward the First of England. Furnes has often been taken by the French; it was carried by Louis XV. in 1744, and restored by him in 1748, under the treaty of Aix-la-Chapelle. It came into the possession of the French at the beginning of the Revolution, and formed part of the department of the Lys until 1814.

The town is well built, and in 1830 contained 756 houses, inhabited by 954 families, and 4253 individuals. There are a cathedral, two churches, a chapel, an hospital, a college, and several convents. A brisk trade is carried on in various kinds of agricultural produce, and the town contains tanneries, breweries, ropewalks, salt refineries, and oil-mills.

Furnes was a place of some importance before the late peace, on account of its fortifications, which have since been demolished.

FURNES CANAL. This work begins at the town of that name, where it is connected with the canals of Bergues, of Loo, and of Dunkerque, and is carried to Nieuport, a distance of five miles and three-quarters. It thus forms part of the canal communication between Bruges and Dunkerque, which is of importance to the trade of the province, and is especially useful for the conveyance of coals. Some considerable works are in progress at Nieuport, which will render this canal further useful for discharging the superfluous water of the Yser into the North Sea.

FURNESS ABBEY. [LANCASHIRE.]

FURRUCKABAD, a district in the province of Agra, forming part of the Doab of the Jumna and Ganges, and lying between 27° and 28° N. lat. This district is bounded on the north by Bareilly and Alighur, on the east by Bareilly, on the south by Etawah and Caunpore, and on the west by Alighur. Previous to 1801 Furruckabad was under a Patan chief, who was tributary to the king of Oude; but in that year, by an arrangement made between the English and that monarch, the tribute was transferred to the East India Company, and in the following year, by a further arrangement made with the nabob of Furruckabad, the Company assumed the civil and military government of the district, making a fixed annual allowance to the nabob of 180,000 rupees (18,000*l.*) It is hardly possible to give too unfavourable a description of the state of anarchy and lawless violence which previous to that time reigned throughout the district. There did not exist even the semblance of a court of justice, in which criminal acts could be punished or civil wrongs redressed. No well-disposed person durst remain abroad after night-fall; houses were forcibly entered by robbers even in the day-time, and murders were commonly perpetrated in the streets in the face of day. Since

the English have assumed the government these evils have been redressed, the persons and property of the inhabitants have been effectually protected; gangs of robbers have been extirpated; and as the consequence of this alteration, the value of houses and land has increased many fold, the assessment has been punctually paid, and cultivation has been greatly extended. According to a statistical return made by the collector of the district in 1813, there were then in cultivation 1,805,383 small begahs, about 600,000 acres of land, the revenue assessed upon which was 10,28,485 rupees (102,848*l.*), or about 3*s.* 5*d.* per acre: there were further at that time 2,97,350 begahs fit for cultivation, and 10,46,704 begahs of waste land in the district, the extent of which appears therefore to be about 1640 square miles.

FURRUCKABAD, the capital of the district, is situated at a short distance from the western bank of the Ganges, in 27° 24′ N. lat., and 79° 27′ E. long.: this is one of the principal towns of Upper Hindustan. It is inclosed by a wall; the streets are wide, and in the best parts of the town the houses are good, and surrounded by trees, but the greater part of the dwellings within the walls are wretched mud hovels. An actual survey of the town was made in 1811, at which time it contained 13,348 dwellings and 1651 shops. Allowing the usual number of five persons to a dwelling, the population must then have amounted to 66,740 persons, exclusive of the floating population, visitors and strangers, which, as Furruckabad is the chief emporium of trade in the ceded and conquered provinces, are always present there in considerable numbers.

FURS and FUR TRADE. The use of furs appears to have been introduced into civilized Europe by the northern conquerors. In the sixth century the skins of sables were brought for sale from the confines of the Arctic Ocean to Rome, through the intervention of many different hands, so that the ultimate cost to the consumer was very great. For several centuries after that time furs could not have become at all common in western Europe. Marco Polo mentions as a matter of curiosity in 1252, that he found the tents of the Cham of Tartary lined with the skins of ermines and sables which were brought from countries far north, from *the land of darkness*. But in less than a century from that time the fashion of wearing furs must have become prevalent in England, for in 1337 Edward the Third ordered that all persons among his subjects should be prohibited their use unless they could spend one hundred pounds a year. The furs then brought to England were furnished by the traders of Italy, who procured them from the north of Asia.

The fur trade was taken up by the French colonists of Canada very soon after their first settlement on the St. Laurence, and through the ignorance of the Indians as to the value of the skins which they sold, and of the trinkets and other articles which they took in payment, the traders at first made very great profits. The animals soon became scarce in the neighbourhood of the European settlements, and the Indians were obliged to extend the range of their hunting expeditions, in which they were frequently accompanied by one or other of the French dealers, whose object it was to encourage a greater number of Indians to engage in the pursuit and to bring their peltries, as the unprepared skins are called, to the European settlements. When the hunting season was over the Indians came down the Ottawa in their canoes with the produce of the chase, and encamped outside the town of Montreal, where a kind of fair was held until the furs were all exchanged for trinkets, knives, hatchets, kettles, blankets, coarse cloths, and other articles suited to their wants, including arms and ammunition. A large part of the value was usually paid to the Indians in the form of ardent spirits, and scenes of riot and confusion were consequently of frequent occurrence.

The next stage of the Canadian fur trade was when some of the European settlers, under the name of *Coureurs des Bois*, or wood-rangers, set out at the proper season from Montreal in canoes loaded with various articles considered desirable by the Indians, and proceeded up the river to the hunting-grounds. Here they remained for an indefinite time, sometimes longer than a year, carrying on their traffic with the Indian hunters, and when their outward investments were exhausted, they returned, their canoes in general loaded with packs of beaver-skins and other valuable peltries. While engaged in these expeditions some of them adopted the habits of the tribe with whom they were associated, and formed connexions with the Indian women. This trade was for some time extremely profitable; the men by whom it was conducted, the *Coureurs des Bois*, were usually without capital, and their investments of European goods were furnished by the storekeepers of Montreal, who drew at least their full proportion of profit from the adventure. The return cargo was generally more valuable than the investments, in the proportion of six to one. Thus where the investment amounted to one thousand dollars, and the peltries returned sold for six thousand, the storekeeper first repaid himself the original outlay, and usually secured for himself an equal amount for interest and commissions, after which the remaining 4000 dollars were divided between himself and the Coureur des Bois.

The Hudson's Bay Company, established with the express object of procuring furs, was chartered by Charles the Second in 1670, with the privilege of exclusively trading with the Indians in the vast and not well defined region lying to the north and west of the great inlet from which the Company takes its name. This association founded several establishments, and has ever since prosecuted the trade under the direction of a governor, deputy-governor, and a committee of management chosen from among the proprietors of the joint-stock, and resident in London. The Company's charter never having been confirmed by Act of Parliament, it was considered that all British subjects were entitled to engage in the trade with those regions, and in conformity with this notion a partnership was formed in 1783 under the name of the North-West Company, which proved a powerful competitor. This Company consisted of twenty-three shareholders, or partners, comprising some of the most wealthy and influential British settlers in Canada, and employed about 2000 persons as clerks, guides, interpreters, and boatmen, or *voyageurs*, who were distributed over the face of the country. Such of the shareholders as took an active part were called agents, some of them resided at the different ports established by the Company in the Indian territory, and others at Quebec and Montreal, where each attended to the affairs of the association. These active partners met once in every year at Fort William, one of their stations near the Grand Portage on Lake Superior, in order to discuss the affairs of the Company, and agree upon plans for the future. The young men who were employed as clerks were, for the most part, the younger members of respectable families in Scotland, who were willing to undergo the hardships and privations accompanying a residence for some years in these countries, that they might secure the advantage of succeeding in turn to a share of the profits of the undertaking, the partners, as others died or retired, being taken from among those who, as clerks, had acquired the experience necessary for the management of the business. This Company had a settlement called Fort Chippewyan, on the Lake of the Hills, in 110° 26′ W. long., and some of the Indians who traded with the persons stationed at this fort came from beyond the Rocky Mountains.

A great degree of jealousy and hostility arose between the respective agents of the Hudson's Bay and North-West Companies, which more or less impeded the operations of both parties for several years, until in 1821 a junction of the two was effected, and the trade has since been prosecuted peacefully and successfully; but their presumed exclusive right of trading throughout the vast region which they have made the scene of their operations, is still guarded with extreme jealousy. All the furs collected by the Hudson's Bay Company are shipped to London, some from their factories of York Fort, and on Moose River, in Hudson's Bay; other portions from Montreal, and the remainder from the Columbia River.

The fur-trade is prosecuted in the north-western territories of the United States by an association called the North American Fur Company, the principal managers of which reside in New York. The chief station of this Company is Michilimackinac, to which are brought all the peltries collected at the other ports on the Mississippi, Missouri, and Yellowstone rivers, and through the great range of country extending thence to the Rocky Mountains. This Company employs steam-boats for ascending the rivers, which penetrate with ease to regions which could formerly be explored only through the most painful exertions in keel-boats and barges, or by small parties on horseback or on foot.

The ermine, called by way of pre-eminence 'the precious ermine,' is found almost exclusively in the cold regions of

Europe and Asia. The stoat (which in fact is identical with the ermine), but the fur of which is greatly inferior to that of the European and Asiatic animal, is found in North America. The fur of the ermine is of a pure whiteness throughout, with the exception of the tip of the tail, which is black; and the spotted appearance of ermine skins, by which they are peculiarly known, is produced by fastening these black tips at intervals on the skins. The animal is from 14 to 16 inches long from the nose to the tip of the tail, the body being from 10 to 12 inches long. The best fur is yielded by the oldest animals. They are taken by snares and in traps, and are sometimes shot, while running, with blunt arrows. The sable is a native of Northern Europe and Siberia. The skins of best quality are procured by the Samoieds, and in Yakutsk, Kamtchatka, and Russian Lapland: those of the darkest colour are the most esteemed. The length of the sable is from 18 to 20 inches. It has been considered by some naturalists a variety of the pine-marten. Martens are found in North America as well as in Northern Asia and the mountains of Kamtchatka: the American skins are generally the least valued; but many among them are rich and of a beautiful dark-brown olive colour. The fiery fox, so called from its brilliant red colour, is taken near the north-eastern coast of Asia, and its fur is much valued, both for its colour and fineness, in that quarter of the world. Nutria skins are obtained from South America, and the greater part of the importations in this country come from the states of the Rio de la Plata. [COYPOU.] These skins are of recent introduction, having first become an article of commerce in 1810: the fur is chiefly used by hat-manufacturers, as a substitute for beaver. Sea-Otter skins were first sought for their fur in the early part of the eighteenth century, when they were brought to Western Europe from the Aleutian and Kurile Islands, where, as well as in Behring's Island, Kamtchatka, and the neighbouring American shores, sea-otters are found in great numbers. The fur of the young animal is of a beautiful brown colour, but when older the colour becomes jet-black. The fur is exceedingly fine, soft, and close, and bears a silky gloss. Towards the close of the eighteenth century furs had become exceedingly scarce in Siberia, and it became necessary to look to fresh sources for the supply of China and other Asiatic countries. It was about the year 1780 that sea-otter skins were first carried to China, where they realised such high prices as greatly to stimulate the search for them. With this view several expeditions were made from the United States and from England to the northern islands of the Pacific and to Nootka Sound, as well as to the north-west coast of America. The Russians then held and still hold the tract of country most favourable for this purpose, but the trading ships which frequent the coast are enabled ...re these skins from the Indians. Fur-seals are in great numbers in the colder latitudes of the southern hemisphere. South Georgia, in 55° S. lat., was explored by Captain Cook in 1771, and immediately thereafter was resorted to by the colonists of British America, who conveyed great numbers of seal skins thence to China, where very high prices were obtained. The South Shetland Islands, in 63° S. lat., were greatly resorted to by seals, and soon after the discovery of these islands in 1818, great numbers were taken: in 1821 and 1822 the number of seal skins taken on these islands alone amounted to 320,000. Owing to the system of extermination pursued by the hunters, these animals are now almost extinct in all these islands, and the trade for a time at least has ceased. The seal-fishery, or hunting, in the Lobos Islands, is placed under restrictive regulations by the government of Monte-video, and by this means the supply of animals upon them is kept pretty regular.

Bears of various kinds and colours, many varieties of foxes, beavers, racoons, badgers, minks, lynxes, musk-rats, rabbits, hares, and squirrels, are procured in North America. Of all the American varieties, the fur of the black fox, sometimes called the silver fox, is the most valuable; next to that in value is the fur of the red fox, which is exported to China, where it is used for trimmings, linings, and robes, which are ornamented in spots or waves with the black fur of the paws of the same animal. The fur of the silver-fox is also highly esteemed. This is a scarce animal, inhabiting the woody country below the falls of the Columbia river. It has long thick fur of a deep lead colour, intermingled with long hairs white at the top, forming a lustrous silver-gray, whence the animal derives its name. The hides of bisons (improperly called buffaloes), of the sheep of the Rocky Mountains, and of various kinds of deer, form part of the fur-trade of North America; and sometimes the skin of the white Arctic fox and of the Polar bear are found in the packs brought to the European traders by the most northern tribes of Indians.

There is but one species of fur which is peculiar to England, the silver-tipped rabbit of Lincolnshire. The colour of the fur is grey of different shades, mixed with longer hairs tipped with white. This fur is but little used in England, but meets a ready sale in Russia and China; the dark-coloured skins are preferred in the former country, and the lighter-coloured in China.

The fur-sales of the Hudson's Bay Company are held every year in the month of March, and being of great magnitude, they attract many foreign merchants to London. The purchases of these foreigners are chiefly sent to the great fair in Leipzig, whence the furs are distributed to all parts of the continent of Europe.

Number of Skins of Fur-bearing Animals imported into the United Kingdom in the year 1835, distinguishing the Countries whence they were imported.

1834	55,357	113,021	168,378
1835	4,340	94,218	98,558

FÜRSTENBERG, a principality under the sovereignties of the king of Würtemberg and grand-duke of Baden, consisting of several mostly isolated bailiwicks on the rivers Danube, Wutach, and Kinzig, the majority of which are situated in the Würtemberg circle of the Danube and the Baden circle of the Lake. They have an area of about 787 square miles, and a population of about 92,000; and comprise 18 towns and 4 market villages, besides 195 villages, hamlets, &c. The principality is mountainous, and produces timber, cattle, iron, copper, silver, &c. In the upland districts, in the western region of the Black Forest, the inhabitants are employed in making articles of wood, particularly wooden clocks. The prince's residence is Donau-Œschingen, where he has his chancery and public offices. He is also possessed of several seigniorialities in Bohemia; and his yearly income is estimated at from 500,000 to 600,000 guilders, from about 46,000*l.* to 55,000*l.* sterling. Donau-Œschingen, in 48° 56′ N. lat. and 8° 31′ E. long., is situated at the confluence of the three streams whose united waters form the Danube. It contains about 400 houses and 3100 inhabitants. The palace, high church, archivarium, public offices, and riding-house and stables are handsome modern buildings: the town has also a gymnasium, and a very extensive establishment belonging to the prince, in which great quantities of beer and brandy are made.

FÜRTH (in Latin records *Trajectum* or *Furthum*), a circle in the Bavarian province of the Retzat, comprising a few small parishes and the town of the same name, which is situated in a fertile plain and at the confluence of the Rednitz and Pregnitz; about four miles north-west of Nuremberg, in 49° 28′ N. lat. and 11° 1′ E. long. It contains about 1240 houses, and 13,850 inhabitants, of whom upwards of 11,000 are Lutherans and 3550 Jews. The site was originally a 'Villa Regia,' or royal domain and mansion, in which many of the German nobles assembled in 907 in council with the emperor Lewis. The bishops of Bamberg enjoyed it by gift from the emperor Henry II.; and it afterwards became part of the Margraviate of Anspach, in conjunction with which it was annexed to the crown of Bavaria in 1803. There are three churches, one of which is Roman Catholic, a splendid synagogue, and three minor places for Jewish worship; the high church contains one of the oldest and largest organs in Germany. The Jews have a sort of university here called a Talmud school, where their learned men and rabbis are educated, two printing-houses, three minor schools, a lay and ecclesiastical court of justice, and a hospital, with an establishment for the employment of their poor and the care of orphans. Fürth has also a townhall, a grammar and a superior civic school, twenty elementary and Sunday schools, an hospital, theatre, &c. The market-place, a large open area, occupies the tongue of land formed by the confluence of the Rednitz and Pregnitz. Independently of a brisk transit trade, Fürth is the residence of a number of small manufacturers, whose productions are looking-glasses, chandeliers, glass, sealing-wax, pocket-books, pencils, needles, spectacles, cabinet work, turnery, false gold leaf (*Leon-gold*), clocks, jewellery, saddles and harness, locks, &c. Some cottons, caps, and stockings are also woven. There is an annual fair at Michaelmas, which lasts fourteen days.

FUSCIN, a brownish matter insoluble in water but dissolved by alcohol, obtained from empyreumatic animal oil. [OIL, ANIMAL.]

FUSEE. [HOROLOGY.]

FU'SELI, HENRY, was the second son of John Caspar Fuessli, a portrait and landscape painter, and author of 'Lives of the Helvetic Painters.' He was born at Zürich in Switzerland, 7th February, 1741. The elder Fuessli gave his son a classical education, and brought him up for the church. He accordingly entered the Caroline College at Zürich, where he subsequently took his degree of Master of Arts. He entered into holy orders in 1761; but having written a pamphlet, in conjunction with Lavater, in which the conduct of an unjust magistrate was exposed, his friends deemed it prudent to oblige him to travel for a while, in order to avoid the vengeance of the disgraced magistrate's family, who still retained considerable power. After travelling in Germany, he came to England, partly it appears as an agent for the purpose of establishing some regular plan of literary communication between that country and his native place. Sir Andrew Mitchell, the British minister at the court of Prussia, furnished him with introductions. Among others, he became acquainted with Mr. Millar (afterwards succeeded by Mr. Cadell) and Mr. Johnson, two eminent publishers; and he supported himself for some time by translating from German, French, and Italian into English, and from English into German. The 'Letters' of Lady M. W. Montagu were among the works he translated into German. In 1765 he published a translation of Winckelmann's 'Reflexions on the Painting and Sculpture of the Antients.' In the following year he set out as travelling tutor to Lord Chewton, the eldest son of Earl Waldegrave; but he soon threw up his charge in displeasure. About this time he became acquainted with Sir Joshua Reynolds, to whom he showed some of his drawings. Reynolds recommended him to devote himself entirely to painting, and he followed the advice.

In 1770 he went to Italy, at which time he altered his name to Fuseli, to suit the Italian pronunciation, and this form he retained after his return to England. In 1778 he visited Zürich on his way back to England. On his return he was engaged by Alderman Boydell, with other artists, to paint pictures for the Alderman's Shakspeare Gallery. About the same period he edited the English edition of Lavater's work on physiognomy, and assisted Cowper in his translation of Homer, with remarks and corrections. In 1788 he married Miss Sophia Rawlins, of Bath Eaton, and subsequently was elected an Associate of the Royal Academy, with a view, it is said by his biographer, to the pension allotted by that body to the widows of its deceased members. In 1790 he was elected Royal Academician. In 1799 he completed a number of pictures, designed from the works of Milton, to form a Milton Gallery, the idea of which was suggested by the Shakspeare Gallery; but he realized nothing by their exhibition. In the same year he was elected Professor of Painting to the Royal Academy, and, in 1803, Keeper. His edition of Pilkington's 'Lives of the Painters' was brought out in 1805. Canova, upon his visit to England, was much struck with Fuseli's works; and on the sculptor's return to Rome, at his recommendation Fuseli was elected a member of the first class in the Academy of St. Luke's. Fuseli died April 15, 1825, and was buried in the crypt of St. Paul's Cathedral.

In the earlier portion of his life Fuseli was very susceptible of the passion of love, and appears to have formed many attachments. He was in like manner favoured with the affections of more ladies than one; but, until he met with the lady whom he married, a curious perversity seems

to have prevented any of the more serious attachments from being mutual. Among others, Miss Wollstonecraft avowed a passion for him, which was not returned. He was short in stature, but robust, with strongly marked features, and an energetic countenance. Harlow's portrait, in little, is esteemed the best likeness of him extant, as it is perhaps the best picture Harlow ever produced. Fuseli had great facility in learning languages. He said that he could think and write with equal ease in French, Italian, and English, but with most power in German. His English writings are in a style not purely idiomatic, but they are full of nerve and originality of expression. His lectures contain (if we except some of his remarks upon contemporaries, which were sometimes all but unavoidably modified by personal feelings), some of the best criticism on the fine arts in the language. Though singularly abrupt and irritable in temper, he made and retained many friendships which were only broken by death. Lavater, Bonnycastle, and Johnson (the publisher), were among the oldest of his friends, and he survived them all. Many curious anecdotes are told of the freedom and quaintness with which he passed his strictures on all persons in matters of art, literature, or manners.

Fuseli made the works of Michel Angelo his chief study. He also moulded his style much upon the model of the colossal statues on Monte Cavallo, at Rome. His colouring is low in tone, and overspread with a sickly, greenish, leaden, or yellowish hue: his hand hasty, and not skilful. He would sometimes work with his colours dry in the powder, rubbing them up with his brush. Probably from a deficiency in his early study, his drawing was not so correct as his ambition was daring. His anatomy sometimes resembles the mechanical and coarse ostentation of an artificial myotomical model rather than the free, varying, and blended forms of nature. The proportions are frequently exaggerated, and the action violent and intemperate. In his desire to display the naked figure, he often sacrifices his better knowledge, and violates all rules of costum and there is sometimes much that is extravagant and fantastical in his design. His figures set about the commonest occupations, straining every feature, finger, and with superfluous energy. His 'Hamlet breakin from his attendants to follow the Ghost' is in a preposterously contorted attitude, and he looks as though he would burst his clothes with convulsive cramps in all his muscles. In an illustration to Cowper's Poems, a gentleman is seated at a family breakfast table without a waistcoat and with his hat on: his legs, which are curiously crossed, seem naked till the slight border of the trowser is perceived. On the other hand, there is always life and action in his figures, some event going forward in the design. His ople seem in earnest. In dreamy or terrible subjects he is often grand and impressive. His 'Nightmare' is imaginative and full of feeling. His 'Sin pursued by Death' is truly a fine picture. Death is fitly hideous, and the female is a ghastly mixture of spectral paleness and voluptuousness. Fuseli loved his art with a genuine affection, and the bold and original thoughts of his vigorous if not exalted mind were impressed upon the canvass without misgiving. He only wanted a better training of his hand, and a more temperate habit of thinking, to have made a great painter. As it is, he has helped to vindicate the supremacy of design (including invention) and expression over the inferior parts of the art, and has done much to advance a better taste in this country. (Knowles.)

FUSION. The different temperatures at which certain solids are rendered fluid have been already mentioned. [FREEZING POINTS.] In addition it may be merely remarked that fusion is sometimes used with the prefix of *watery*, and at other times *igneous*. Watery fusion is that which occurs when a salt, such as sulphate of soda for example, containing much water of crystallization fuses or melts in its water by exposure to a moderate heat; it may afterwards undergo igneous fusion by exposure to a much higher temperature.

FUST, or FAUST, JOHN, an opulent citizen of Mayence, a goldsmith by trade, whose name appears as one of the inventors of the art of printing, in the manner in which that art is effected by movable metal types. Gutenberg and Schoeffer were the two others. Schoeffer, by inventing the puncheon, is supposed to have given completion to the discovery. It is not however quite certain that Fust did more than supply money to Gutenberg, who had made attempts with movable metal types at Strasburg, before he removed to Mayence in 1444-1445. Fust entered into partnership with him; but soon after, in consequence of a law suit, the partnership was dissolved, and the whole of Gutenberg's printing apparatus fell into Fust's hands, who ultimately, with the assistance of Peter Schoeffer, made the invention useful to the world. The Latin Bible in folio, commonly called the Mazarine Bible, executed between 1450 and 1455, if it was not by Gutenberg, is supposed to be the earliest production of their press.

The books with dates which bear the joint names of Fust and Schoeffer are: 1. The Latin Psalter of 1457, in large folio; the type of the size used in the great service books of the Romish Church. At the end is this subscription—

> "Adinuentione artificiosa imprimendi ac caracterizandi absque calami ulla exaratione sic effigiatus. Et ad eusebiam dei industrie est consummatus per Johannem fust Cinem Maguntioum. Et Petrum Schoffer de Gernszheim. Anno dni Millesimo CCCC.LVII. In vigilia Assumptionis."

2. The Psalter of 1459; with some variations from the preceding, but in the same size and letter. 3. The 'Rationale divinorum Officiorum' of Durand, 1459, fol. maj.; the first specimen of the smaller type of Fust and Schoeffer. 4. The Clementine Constitutions, 1460, fol. maj. 5. Joannis Balbi de Janua Catholicon, 1460, fol. maj. 6. The Latin Vulgate Bible, 2 vols., 1462, fol. maj. Copies of this Bible are oftener found printed upon vellum than on paper, but both are rare. 7. The German Bible, fol. maj. [Known to have been printed in 1462, or thereabout.] Reprinted in 1465. 8. 'Bulla Papæ Pii II.' Germ. 1463, fol. maj. 9. 'Liber sextus Decretalium Bonifacii VIII. Pont. Max.' 1465, fol. maj.: a second, or at least a varying impression of this work appeared in the same year. 10. Cicero's Offices and 'Paradoxa,' 1465, sm. fol.: the first edition of Cicero with a date. 11. Cicero's Offices and Paradoxa, 1466, sm. fol. Copies of this edition are more common upon vellum than on paper: that of 1465 is very rare upon vellum. 12. 'Grammatica rhytmica,' 1466, fol. min. It consists of eleven leaves in the smallest fount of type of these printers, and is of extreme rarity; two or three copies only are known.

The following works without date, from the close resemblance of their typography, are assigned without scruple by our best bibliographers to the press of Fust and Schoeffer. 1. 'Bulla Cruciata sanctissimi Domini nostri Papæ contra Turcos,' fol. in six printed leaves. It has no place or name. The type is like the Durand. 2. 'Laus Virginis,' folio, nine leaves. The device of the shields in red, at the end, seen in so many of these printers' works, decidedly justifies its being placed as the production of Fust and Schoeffer's press. 3. 'S. Aurelii Augustini de Arte prædicandi Tractatus,' folio: supposed to have been printed about 1466. It consists of twenty-two leaves. 4. 'Ælius Donatus de Octo partibus Orationis,' 4to.; the type of the smaller size, resembling the Latin Bible of 1462 and the Cicero of 1465.

With an exception or two, the whole of Fust and Schoeffer's productions are in the collection at the British Museum.

Fust, whose name appears with Schoeffer's for the last time in 1466, is supposed to have died in that, or at latest in the next year, of the plague, at Paris. Schoeffer continued to print in his own name for a long time.

(Panzer, *Annal. Typogr.*, vol. ii., p. 111-117; *Bibliot. Spenceriana*, passim: *Biogr. Universelle*, tom. xvi. p. 205; Peignot, *Variétés, Notices, et Raretés Bibliographiques*, 8vo. Par. 1822, p. 78.)

FUSTIAN, a description of cotton fabrics similar in the mode of their manufacture to velvet, having in addition to the warp and weft common to all woven goods, a *pile* consisting of other threads doubled under the weft, and 'thrown in' at intervals so close together that when the goods are finished the interlacing of the warp and weft are concealed by them. [VELVET.] While in the loom the pile forms a series of loops, which are afterwards cut and sheared. The cutting is performed by running a knife through each series of loops as they occur in the weft; this gives an uneven and hairy appearance to the cloth, which is afterwards remedied first by the shearing process, and afterwards by singeing and brushing, which latter operations are re-

peated until the fustian has acquired a smooth and polished appearance. The shearing of fustians is a separate art; and several hundred persons are engaged in it in the town of Manchester alone. Until lately the operations were conducted by hand, but the aid of machinery has now been obtained, and instead of the tedious operation of cutting open only one set of loops at once, a series of knives are brought to act together and continuously, until the whole piece is finished, by which means the work is not only done more quickly, but is also better performed than when its excellence depended upon the uniform precision of the human hand.

Various kinds of fustians are made, and are known by different names, according to their form and fineness. The best kinds are known as cotton velvet and velveteen; besides these there are beaverteens, moleskin, corduroy, and cords. Different patterns are produced by different dispositions of the pile threads. Fustians are woven both in the hand-loom and with the power-loom; they are made of different widths, some pieces being 18 and others 27 inches wide: a piece of velveteen of medium quality, 90 yards long and 18 inches wide, weighs about 24 or 25 lbs. The yarn for the warp is made of New Orleans cotton, or of Upland Georgia and Brazil cotton mixed, of the fineness of 32 hanks to the pound; the weft and pile are usually spun from Upland mixed with East India cotton, and the yarn is commonly of the fineness of 24 hanks to the pound. [COTTON SPINNING.]

FUSTIC. This name appears to be derived from *fustel*, the French name of a yellow dye-wood, the produce of Venetian sumach. A wood similar in colour and uses, but larger in size, having been subsequently imported from the New World, had the same name applied to it with the addition of *old*, while the other, being smaller, is called *young fustic*: but these, so far from being the produce of the same tree at different ages, do not even belong to the same genus.

Young Fustic, or, as it is sometimes called, *Zante Fustic*, is the produce of Rhus Cotinus (tribe *Anacardiaceæ*), a native of Italy, the south of France, and of Greece; much of it is exported from Patras in the Morea; and it also extends into Asia. It is supposed to be the Cotinus of Pliny, being still called *Scotino* near Valcimara, in the Apennines, where it is cultivated on account of its uses in tanning. The root and the wood of this shrub are both imported, deprived of their bark, and employed for dyeing a yellow colour approaching to orange, upon wool or cottons, prepared either with alum or the nitro-muriate of tin with the addition of tartar. The colour is a beautiful bright yellow, and permanent when proper mordaunts are employed. Only small quantities of this kind of fustic are imported.

Dr. Sibthorp was of opinion that *Rhamnus infectoria* or *oleoides*, of which the berries are called French and Persian berries, yielded the *fustic* of commerce, and informs us that its yellow wood is called by the Greeks *chrysoxylon*. He also thought that it was the *Lycium* of Dioscorides, but this has been shown by Dr. Royle to be a species of Berberis, of which genus all the species have yellow wood.

Old Fustic, the 'bois jaune' of the French, is on the contrary the produce of a large tree, *Morus tinctoria*, dyer's mulberry, of the natural family of Urticeæ, a native of Tropical America and the West India Islands. The tree attains a height of 60 feet; the wood is yellow coloured, hard, and strong, but easily splintered, and is imported in the form of large logs or blocks. The yellow colour which it affords with an aluminous base, though durable, is not very bright. M. Chaptal discovered that glue, by precipitating its tannin, enabled its decoctions to dye yellow almost as bright as those of weld and quercitron bark. The fustic from Cuba is preferred, and fetches the highest price, varying from 10*l*. to 12*l*., while that from Jamaica or Columbia varies from 8*l*. to 9*l*. a ton. The tree is figured by Sloane, and noticed by Marcgrave and Piso. Browne describes it as a native of Jamaica, and deserving the attention of planters, as it is only propagated by birds, who are fond of its sweet roundish fruit.

Fustic is admitted into England at the nominal duty of three shillings per ton from British Possessions, and four shillings and six-pence from other countries. The annual import for each of the ten years, ending with 1836, was—1827, 4111 tons; 1828, 7597; 1829, 7364; 1830, 5111; 1831, 6334; 1832, 4350; 1833, 9851; 1834, 14,047; 1835, 9930; 1836, 4917.

The several countries from which fustic was imported, and the respective quantities received from each, were, in 1836—

FUSUS. [SIPHONOSTOMATA.]

FUTTEHGHUR, a town in the district of Furruckabad distant 3 miles from the city of Furruckabad, on the western bank of the Ganges, in 27° 21′ N. lat. and 79° 30′ E. long. Futtehghur was formerly an important military station of the British government; but since the district has become more subject to the dominion of the law than it was when under the government of the nabob of Furruckabad, the number of the soldiers has been diminished, and is now quite inconsiderable. This town is the residence of the civil officers entrusted with the management of the conquered and ceded provinces, and several European merchants reside and carry on their business within its walls. During the dry season the Ganges is here reduced to two or three narrow channels winding slowly through a bed of sand, and at this time the town is hardly habitable because of the clouds of dust which are continually flying. The town contains an arsenal which is protected by a strong mud fort. The chief industry carried on within the town is the manufacture of tents, which are made of good materials and excellent workmanship. Futtehghur is distant 90 miles north-west from Lucknow, travelling distance.

FUTTIPORE, a town situated 19 miles south-west from the city of Agra, and within the province of that name, in 26° 6′ N. lat. and 77° 34′ E. long. The walls by which it is surrounded are of great extent. The inclosed space appears for the most part to have been always unprovided with buildings. The stone of which the walls are formed is furnished by quarries in the neighbourhood, which have also supplied the materials for building the houses, which are not numerous. The town was inclosed and fortified by the Emperor Akbar, whose favourite residence it was. It contains an extensive tomb, also built by Akbar, in which several members of the imperial family were buried: the palace which he inhabited has long been in ruins, while a small house, which is said to have been the residence of his favourite minister, is still in good preservation.

FUTURE. [TIME.]

FUZE, a short tube, made of well-seasoned beech, and fixed in the bore of a shell. It is filled with a composition, which, being fired by means of a small piece of quick-match inserted for the purpose, the shell is made to explode in consequence of the fire communicating with the powder with which it is charged. The length of a fuze is regulated by the intended range of the shell or by the intended time of its flight.

For the ingredients which enter into the composition, and for the manner of 'driving' the fuze, see Spearman's *British Gunner*.

FYZABAD, a town in the kingdom of Oude, situated on the south side of the Goggra river, in 26° 47′ N. lat. and 82° 3′ E. long., 2 miles west from Oude, the antient capital. In the reign of Shuja ud Dowlah, Fyzabad was made the capital, but the seat of government was transferred to Lucknow, in 1775, by his son and successor Azoph ud Dowlah. Shuja's palace is already in ruins. At the time just mentioned, the bankers and superior merchants accompanied the court to Lucknow, but the population is still numerous. The widow of Shuja ud Dowlah, known in history as the Bhow Begum, continued to reside in Fyzabad to the time of her death. She was possessed of great wealth, the amount of which, as is usual in the East, was much exaggerated. She wished to bequeath the whole of her property to the English government, but the offer was declined; and after providing for her other relations

and dependants, the bulk of her fortune descended to her grandson Ghazi ud Deen, king of Oude. It required a sum equal to about 680,000*l.* to provide for the payment of the various legacies and pensions bequeathed by the Begum's will, after which the king of Oude succeeded to landed property (jaghires) yielding 80,000*l.* per annum and money to the amount of 270,000*l.*, besides jewels, shawls, and cattle, the value of which was very great, but was not ascertained. Fyzabad is 78 miles east from Lucknow, travelling distance.

INDEX TO THE LETTER F.

VOLUME X.

VOLUME XI.

G.

G. This letter is derived from the Latin alphabet, in which it first appears. In the Greek alphabet its place is supplied by *zeta*. If, as seems probable, the sound of this Greek letter was the same as the consonantal sound at the beginning of the word *judge* (see Z), it may perhaps be inferred that the hissing sound now given to the letter *g* existed already in some dialect of antient Italy. The sound at any rate is familiar to the modern Italian. The sound of the letter *g* in the English language is two-fold. Before *a*, *o*, and *u*, and occasionally before *i* and *e*, it is the medial letter of the guttural order. The other sound, which it possesses only before *i* and *e*, is one of the medials of the sibilant series, and is also represented by the letter *j* as pronounced by the English. [ALPHABET, p. 379.] The sibilant sound is written in Italian by two letters, *gi*, as Giacomo, Jacob, or by *gg*, as *oggi*, to-day. The two-fold nature of the sound corresponds to the double sound of the letter *c*, which is sometimes a *k*, sometimes an *s*. [See C.]

The guttural *g* is liable to many changes in different dialects or languages.

1. *g* and *k* are convertible. Thus the Greek and Latin forms genu, γονυ; gen, γεν, as seen in gen,us, γεν,ος, gi,g(e)n,o, γι,γ(ε)ν,ομαι; gno, γνω, as seen in gno,sco, γι,γνω,σκω; severally correspond to the German and English *knie*, *knee*; *kind*, *kin*; *kenn,en*, *know*.

2. *g* and an aspirated guttural: as, Greek, χην; German, *gans*; English, *goose* and *gander*. Perhaps χαινω may be related to the German *gaffen* and English *gape*. There can be no doubt as to the connexion between the Greek χθες, the Latin *hes-ternus*, and the German *ges-tern*. The close connexion of the two sounds may also be seen in the pronunciation of the final *g* in high German like *ch*, as *Ludwig*, &c.

3. *g* and *h*. As the letter *h*, when pronounced at all, is only a weak aspirate, this interchange strictly belongs to the last head. As an additional example, we may refer to the Latin word *gallus*, which has all the appearance of being a diminutive, like *bellus*, *ullus*, *asellus*, from *benus*, *unus*, *asinus*. If this be admitted, the primitive was probably *ganus*; and we see its corresponding form in the German *hahn*, a cock.

4. *g* often disappears: First, at the beginning of a word, as in the Latin *anser*, a goose, compared with the forms given above, and in the English *enough* compared with the German *genug*. A large number of examples of this may be seen in the poetical participles of the English language, commencing with a *y*, as *yclept*, *yclad*, &c.: also in *ago* for *agone*; in all of which the fuller form began with *ge*, as is still seen in German. The loss of *g* is particularly common before *l* and *n*, as Eng. *like*, Germ. *gleich*; Lat. *nosco*, *nascor*, from *gnosco*, *gnascor*. Secondly, in the middle of words between vowels. This may be seen in French words derived from the Latin, as: *legere*, *lire*, read; *magister*, *maistre*, master; *Ligeris*, *Loire*, &c.; also in English words connected with German, as, *nagel*, *nail*; *segel*, *sail*; *regen*, *rain*, &c. In such cases the vowel is generally lengthened. Lastly, at the end of words, as, *sag-en*, *say*; *mag*, *may*; *tag*, *day*: here again the syllable is strengthened.

5. *g* and *y* are convertible: as, *yester-day*, compared with the Germ. *gestern*; *yawn* with *gähn,en*; *yellow* with *gelb*. In our own language we find related words showing this difference: *yard* and *garden*; *yate*, a dialectic variety of *gate*; *yave* for *gave* (Percy's *Reliques*, i., p. 294, note); and *yode*, a perfect of *to go* (Glossary of same).

6. *g* with *gu* and *w*. In the Latin language there co-exist the forms *tinguo*, *tingo*; *unguo*, *ungo*; *urgueo*, *urgeo*, &c. In the French language *gu* is presented to the eye, but *g* to the ear, in the following: *guerre*, *guêpe*, *guarder*, &c.; while in English we have *war*, *wasp*, *ward* or *guard*. Under this head it may be observed, first, that a final *w* in the English language often corresponds to a guttural in other Teutonic dialects, as *saw*, *raw*, *crow*, *row*, *maw*, &c.; secondly, that we often have two letters, *ow*, where the German has a guttural *g*, as *follow*, *sorrow*, *morrow*, *furrow*, *gallows*, *marrow*, *borrow*, *barrow*.

7. *g* and *b*. This is generally confined to those cases at the beginning of words, when an *r* or *l* follows, as in the Æolic forms, γλεφαρον, γληχων, γαλανος, in place of βλεφαρον, βληχων, βαλανος. Hence the Latin *glans*. So the Turks have given to Prussia the name of *Gharandaberk*, i. e. *Brandenburg*.

8. *g* and *d*: as δη-μητηρ for γη-μητηρ. Examples of this interchange may be heard from the mouth of nearly every child in its first attempts to speak, as *Dy Flot* for *Guy Fawkes*, *dood boy*, *do away*, &c. This change, as in the last case, is common before *l*; hence the Latin *dulcis* by the side of the Greek γλυκυς.

9. The guttural g and the sibilant g. It was stated in C that the hard sound of that letter in the Western languages of Europe often corresponded to a hissing sound in the Eastern. So too the hard *g* belongs to Europe, the *j* sound to Asia. Thus *reg*, a king, is in the East *rajah*.

10. The sibilant *g* and *di* or *bi* before a vowel. For examples see D and B.

11. *g* appears to attach itself to the letter *r* at the end of roots: as, *merg,o*, *sparg,o*, compared respectively with the Latin *mare* and the Greek σπειρω. This outgrowth corresponds to the addition of *d* at the end of roots ending in *n*. [See D.] The two liquids take as an addition the medial consonants of their own order, the dental *n* preferring the dental *d*, while *r* takes to it the guttural *g*.

G (in music), the fifth note or degree of the diatonic scale, answering to the *sol* of the Italians and French. It is also a name of the treble clef. [CLEF.]

GABION, a hollow cylinder of wicker-work, resembling a basket, but having no bottom. It is formed by planting slender stakes vertically in the ground, at intervals from each other on the circumference of a circle, and interweaving with them osiers or other flexible twigs.

The most usual kind of gabion is about 20 inches in diameter, and 2 feet 9 inches in height, but the stakes, whose extremities are pointed, project beyond the basket-work about 3 or 4 inches at each end. The lower ends of the stakes, by entering the ground, serve to keep the gabion in its place when set up; and as it is usual to increase the height of a row of gabions by placing along their tops a triple line of fascines, the upper ends of the stakes retain the fascines in their places by entering between the rods.

Such gabions are used during a siege in executing trenches by the process of sapping: for this purpose they are placed on end, with their sides inclining a little outwards, on that side of the line of approach which is nearest to the fortress; and, being filled with earth obtained by the excavation of the trench, they form a protection against the fire of the enemy. After the gabions are filled, the required thickness is given to the parapet of the trench by throwing the earth beyond the line.

Gabions of the same kind are sometimes used to form a revetment for the interior of the epaulement of a battery; being then placed on end in two or more horizontal rows, one above the other, and leaning against the mass of earth. Four or five gabions line each side or cheek of the embrasure at the neck or interior extremity of the latter.

What is called a sap-roller consists of a gabion placed within a larger one, so that their axes are coincident: each is about 6 feet long, but the diameter of the exterior gabion is 4 feet, and that of the other 2 feet 9 inches, and the interval between the two is filled with brushwood or any light material by which the whole may be rendered musket-proof. This is used to cover the sappers in front, while employed in excavating the approaches near the fortress, being rolled forward as the work advances.

It has been recommended to place a row of small gabions, in the form of frustums of cones, along the crest of a parapet, in order to cover the heads of the defenders: bags of earth are usually employed for this purpose: but if gabions should be preferred, their large ends must be placed upwards, so as to leave between every two at bottom a loophole for musketry.

A *gabionnade* is any lodgment consisting of a parapet hastily formed by placing on the ground a row of gabions, and filling them with earth obtained by digging a trench parallel to the line, in their rear

GABRES. [Guebres.]

GADEBUSCH, FREDERIC CONRAD, a learned German, born in 1719, in the island of Rugen. After having studied at different universities of Germany, he went, in 1750, to Livonia, where he remained till his death in 1788. He was a very laborious writer, and left several works in German, which throw considerable light on the history of the Baltic provinces of Russia. His principal works are: 'Memoir on the Historians of Livonia,' Riga, 1772; 'Livonian Bibliotheca,' Riga, 1779; 'Essays on the History and Laws of Livonia,' Riga, 1777-1785; 'Annals of Livonia, from 1030 to 1761,' 8 vols. in 8vo., Riga, 1780-1783.

GADES. [Cadiz.]

GADFLY. [Œstridæ.]

GADIDÆ, a family of fishes of which the common codfish may serve as the type. [Abdominales; Malacopterygii.]

GAEL, GAELIC. Although the language spoken by the Scottish Highlanders is familiarly known among the Lowlanders by the name of the *Erse*, or, according to the more usual pronunciation, the *Ersh*, that is, plainly, the Eirish or Irish, the people themselves are never called by that name. Among the Highlanders the name Erse is unknown, either as that of the nation or of the language. They call themselves only the *Gadhel*, also sometimes written and always pronounced *Gael*, and their language the *Gaedheilg*, pronounced *Gaeilg*, or, nearly *Gaelic*. The name *Gaelic* is also in familiar use among the Lowlanders as that of the language. Further, the only name by which the Irish are known to the Scottish Highlanders is *Gael*: the latter call themselves *Gael Albinnich*, or the Gael of Albin, and the Irish *Gael Erinnich*, or the Gael of Erin. The Irish also call themselves the *Gadhel*, or *Gael*, and their language the *Gaelic*. Finally, the Welsh call the Irish *Gwyddel*, which is evidently the same word with *Gadhel*, or *Gael*.

This is nearly all that can be stated as matter of fact in regard to the name *Gael*. The rest is all speculation and conjecture: of that, however, few words have given rise to so much. We shall not here attempt to do more than to indicate and arrange the various points as to which many volumes of philological and historical controversy have been written.

1. It has been generally assumed and admitted that the modern Gael are a portion of the *Galli*, or Gauls, of antiquity, the people who gave its former name to the country now called France, and who were principally, though by no means exclusively, known to the Greeks and Romans as the inhabitants of that region. Although however this opinion has been commonly adopted, the grounds upon which it has been taken up do not appear to be very conclusive. They are principally the similarity of the two names—some historical and traditional testimony to the fact that South Britain was originally peopled from Gaul—some traces, rather faint and disputable, of identity of institutions and customs—and what would be the strongest argument, if it were well made out, the evidences of identity of language conceived to be established by the comparison of the names of places in France, and a few other remains of the old language spoken there, with the modern Gaelic of Scotland and Ireland. But the supposition is not unattended with difficulties, and if adopted it does not clear up the question of how the Gauls got either to Scotland or to Ireland.

2. Supposing the Gael to be the *Galli* of the Roman writers, and the Galatai (Γάλαται) of the Greeks, a question arises as to whether these names are the same with the *Celtæ* or *Celti*, or *Keltai* (Κελται), sometimes spoken of by the antients as a general name for the Gauls, sometimes as the name of only a certain portion of the Gauls. [Celtæ.] And if the *Gauls* and the *Celts* were distinct names, it remains to be settled which was the general name of the nation, and which the name only of the division or tribe. Several antient writers have represented the *Celts* to be the most antient name of the nation, and the *Gauls* to be a name substituted at a comparatively late period; but it has been contended in modern times on very plausible grounds that this notion is a mistake, and that the Celts were only a section of the Gauls, which was always the generic name.

3. Then there has been a world of controversy about the origin and meaning of both *Gael* and *Celt* (antiently, it is to be remembered, pronounced Kelt); the confusion here again being increased by the difference of opinion as to whether these are different words or only different forms of the same word. Of Gael, taken by itself and assumed to be different from Celt, it cannot be said that anything has been made; all the derivations suggested are puerile. On the assumption that it is the same with Celt, it has been found perhaps somewhat less intractable; but this cannot be received as a proof that that assumption is correct. The most probable account of Celt is that which connects it with the Gaelic *Caoill*, a wood—perhaps the same with the Greek *Kalon* (Κάλον) wood—whence *Caoiltich*, a people inhabiting a woody country. This is also the origin commonly assigned to the name *Caledonii*; which is supposed to be *Caoildaoine*, literally 'wood-people,' or people of the woods. The inquiry into the meaning of the word *Gael* has been greatly embarrassed by its similarity to another word still used in the Gaelic both of Scotland and Ireland, and which curiously enough seems to have the very opposite meaning to Gael. Thus, while the Scottish Highlanders call themselves Gael, they call all the rest of the Scotch, who do not speak Gaelic, by the name of *Gaoill*, or in the singular *Gaoll*, which they understand to mean strangers or foreigners. Thus *Gaolldoch* is the country of the Scots who speak English; *Gaeldoch*, the country of the Highlanders who speak Gaelic. In the same manner *Gall* is the Irish term for a stranger, or one speaking a different language; but it is very remarkable that this fact should have been advanced by Mr. Moore in his late 'History of Ireland' (i. 3) as a proof that the Irish do not consider themselves as being of Gaulish origin, while he must have known that they at the same time call themselves *Gael*—a fact however to which he has not, as far as we can find, adverted in any part of his work. Then, after all, comes to be considered the possible connection between either Gael or Gaoll and the *Wealh* of the Anglo-Saxons, whence our modern Welsh and Wales, and which seems to be the same with the Wälsh, applied generally to foreigners by the modern Germans. Were the Cymry called Wealh by the Saxons (whence the French have made *Galles*, as we have made *Welsh*) because they were considered to be Gael or Gauls, or because they were held to be strangers, foreigners, aliens?—or is it possible that the two words which appear in the modern Gaelic and Irish in the slightly distinguishable forms of Gael and Gaoll or Gall, notwithstanding their apparently opposite significations, may after all be only different forms of the same word?

4. The last class of disputed points we shall mention are those arising out of the history of the various nations and languages which are either Gaelic, or have by some been assumed to be Gaelic. What was the real amount of the connection or distinction between the antient Gauls and Germans? In what relation to either stood the Iberians? in what the Celtiberians? in what the Aquitanians? Were the Cimbri Gauls or Germans? Were the Belgæ Gauls or Germans? Whether or in what degree is the Gaelic tongue related to what have been called the Indo-Germanic languages? Is there any connection, and to what amount, between the Gaelic and the Semitic languages? These are the principal questions that have been agitated with regard to the Gael or supposed Gael of the antient world. Their modern history has afforded fully as many more. Was Britain originally peopled by a Gallic or Germanic race? Were the Picts Gauls or Germans? Were the Caledonians Gauls or Germans? Were the more recently-settled colonists whom Cæsar found in the South of Britain of Gallic or Germanic stock, and did they speak a Gaelic or Teutonic language? What is the degree of affinity between the Welsh tongue and that spoken by the native Irish and the Highlanders of Scotland? Is it a dialect of the same tongue, or (as has lately been strenuously maintained) a language of altogether a distinct family? Is the Basque a Celtic dialect? Whence came the Irish, supposing them to be Gael from India? or Persia? or Phœnicia? or Spain? or France? or England? or Scotland? Were the Scots or Milesians of Ireland a Gallic or Germanic people? What is the origin of the present Highlanders of Scotland? Are they the progeny of a comparatively recent Irish colonization, as has of late been generally agreed, and as their own traditions have always asserted? or are they the descendants of the antient Caledonians, assumed on that supposition to be Gauls, and to have been the original population of the whole island, who were, probably a short time before the commencement of the Christian æra, driven from South to North Britain before a new immigration from the continent? All or most of these may be considered as questions still doubtful and disputed.

It would occupy much more space than we can afford to enumerate even the more important works in which these various controverted points have been discussed in our own and other languages. We shall only mention that the most recent publication which has appeared on the subject of the Gael in English is 'The Highlanders of Scotland, their Origin, History, and Antiquities,' by W. F. Skene, 2 vols. 8vo. London, 1837, being an essay to which a prize had been awarded by the Highland Society of London. Mr. Skene's views and reasonings are of very considerable ingenuity as well as novelty; but whatever may be thought of the part of it which relates to the origin of the Gael, the work is undoubtedly in other respects one of the most important contributions to early Scottish history that modern research has furnished.

GAE'TA, a strongly fortified town and a bishop's see in the province of Terra di Lavoro in the kingdom of Naples, is situated on a lofty promontory which projects into the Mediterranean, and forms one side of the gulf of the same name, the antient Sinus Formianus, which almost rivals in beauty of scenery the neighbouring Bay of Naples. The islands of Ponza, Vandotena, and Ischia are seen at a distance. Inland to the northwards, the Apennines rise above the wide unwholesome plains extending to the sea-coast: through these plains flows the Garigliano, or Liris, near the mouth of which stood the antient Minturnæ, of which few traces remain except some arches of its aqueduct. In the immediate neighbourhood of Gaeta the Formian hills are covered with vineyards, olives, oranges, and other fruit-trees, and at the foot of them, in the innermost recess of the gulf, is Mola, near the site of the antient Formiæ, which was destroyed by the Saracens in the ninth century. Cicero's Formianum was in this neighbourhood, about half-way between Mola and Gaeta, at a place called Castellone ('Antichitá Ciceroniane ed Iscrizione esistenti nella villa Formiana in Castellone di Gaeta,' by the Prince of Caposele, Naples, 1827, with plates). The monument near Mola, which is vulgarly called Torre di Cicerone, is not the tomb of the orator.

Gaeta with its suburbs has a population of about 10,000 inhabitants, exclusive of the garrison. It has sustained several sieges, the last of which was in 1806 against the French. It has a harbour, and carries on some trade by sea. Caieta, which appears to have been an old Greek colony, was not a place of great importance under the Romans: it has however some remains of antiquity, among others the circular monument called Torre di Orlando, which is the mausoleum of L. Munatius Plancus, a friend of Augustus; and another tower, called Latratina, which was once part of a temple. In the cathedral is a baptismal vase of Parian marble with highly finished rilievos, besides other remains. Gaeta is the head town of a district which extends from the Garigliano to the frontier of Rome. [TERRA DI LAVORO.]

GAFFURIUS. [GAFORIUS.]

GAFO'RIUS, FRANCHI'NUS, or FRANCHINO GAFORI, a very learned writer on music, was born of humble parents, at Lodi, in 1451. In his boyhood he was devoted to the service of the church, and among other branches of knowledge to which he applied himself with marked diligence, he studied music under a Carmelite friar named Godendach, of which science, both theoretically and practically, he became a complete master. It does not seem certain that the sacerdotal dignity was ever conferred on him, though it has been confidently stated that he entered into holy orders. He first went to Verona, publicly taught music there during some few years, and also wrote his work, *Musicæ Institutiones Collocutiones*. The reputation he thereby acquired, procured him an invitation from the Doge to visit Genoa, which he accepted, but soon after proceeded to Naples, where he met Tinctor, Garnerius, Hycart, and other celebrated musicians, and, according to the usage of the time, held public disputations with them. At Naples he also produced his *Theoricum Opus Harmonicæ Disciplinæ*. But the Turks having brought war and the plague into the Neapolitan territory, he was driven from that part of Italy, and by the persuasion of Pallavicini, bishop of Monticello, returned to Lodi, gave lectures on music, and began his *Practica Musicæ utriusque Cantus*, his greatest work, which was first printed at Milan in 1496. Of this, Sir J. Hawkins has given a copious abstract, an honour to which it was entitled, not only on account of it intrinsic merit, but because it is the first treatise on the ar that ever appeared in print. It is full of that kind of information which was called for, and proved eminently useful at the period in which it was published, quickly spreading the author's fame throughout Europe. But, touched by the pedantic spirit of the age, he invented terms that must have cost him infinite labour to compound, and which doubtless exacted no less from his readers before they could understand them. His work lying before us, we are tempted to give a specimen of the language of art adopted in the fifteenth century, as it appears in the heading of one of his chapters: *De Proportione Subquadruplasupertripartientiquarta.*

Gaforius (erroneously called Gaffurius by Hawkins, Burney, &c.) wrote other works, which were held in high estimation. It is supposed that he died in or about the year 1520.

GAGE, any apparatus for measuring the state of a phenomenon. But the term is usually restricted to some particular instruments, such as the gage of the air-pump, which points out the degree of exhaustion in the receiver, the wind-gage [ANEMOMETER], the tide-gage, &c., &c., all of which are mentioned in connexion with their several subjects.

GAHNITE, a mineral so called from the name of its discoverer, Gahn; it is sometimes also called automalite and zinciferous spinel. It occurs crystallized in regular octohedrons and varieties. Sp. gr. from 4·1 to 4·8. Hardness 8. It is of a dark bluish-green colour, nearly opaque; may be cleaved parallel to all its planes. Before the blowpipe it is unalterable alone, and nearly so with fluxes.

It occurs at Fahlun, in Sweden, and Franklin, in America; both varieties have been analyzed by Abich, with the annexed results:—

	Sweden.	America.

GAIL, JEAN BAPTISTE, born at Paris in 1753, distinguished himself in the study of Greek, and was made, in 1791, Professor of Greek Literature in the College de France. In 1794 he married Mademoiselle Sophie Garre, who afterwards became celebrated as a musical composer. Her husband has written a number of works, chiefly translations from the Greek; a Greek grammar, 1799, with a supplement, or 'Essai sur les Prépositions Grecques considérées sous le rapport Géographique,' 1821; and 'Cours de Langue Grecque, ou Extraits de differens Auteurs,' in four parts, 1797-99. He wrote also 'Observations sur les Idylles de Théocrite et les Eclogues de Virgile,' 1805; and lastly he furnished the materials for the 'Atlas contenant par ordre de temps, les Cartes rélatives à la Géographie d'Herodote, Thucydide, Xenophon, les plans de bataille,' &c., 4to. Paris; to which are added 'Observations Préliminaires,' and an Index, by Gail. Gail was made Knight of the Legion of Honour by Louis XVIII., and Knight of St. Wladimir by the Emperor Alexander.

GAILLAC. [TARN.]

GAILLARD, GABRIEL HENRI, a celebrated modern French historian, was born in 1726. After receiving a good education, he was admitted advocate at an early age, but he soon left the bar in order to devote himself entirely to literature. In 1745, when he was only 19 years old, he wrote a treatise on rhetoric for the use of young ladies. In 1757 he published the History of Mary of Burgundy, daughter of Charles the Bold and wife of the Emperor Maximilian I. This work had great success. In 17[illegible] was published his 'History of Francis I. of France.' It is the general opinion that he did full justice to this subject, though he presented it in a rather uninviting form for the generality of readers, having divided the history of that celebrated reign into separate parts, such as civil, political, military, ecclesiastical, and literary history, the private life of the king, &c. The author adopted the same plan in his 'History of Charlemagne,' 1782, in 4 vols. 4to. Besides the objection to his mode of dividing the subject-matter, it was further objected to the 'History of Charlemagne' that he had sunk the biography of his hero between two long dissertations on the first and second races of the French kings. Notwithstanding these defects, the work met with great success, and received the praises of Gibbon and of

the celebrated German historian Hegewisch, who himself wrote a history of Charlemagne in German. The best work of Gaillard is his 'History of the Rivalry between France and England,' of which the first three volumes appeared in 1771, the four following in 1774, and the four concluding volumes in 1777. This work embraces not only the political and military relations between the two countries, but also the internal history of both, so arranged as to present a constant parallelism. His 'History of the Rivalry between France and Spain,' 8 vols. in 12mo., a work highly appreciated in France, is written on the same plan. Gaillard was the author of the 'Historical Dictionary' in the 'Encyclopédie Méthodique,' 6 vols. in 4to., and many other minor works, the most valuable of which are a 'Life of Malesherbes,' his personal friend, 1805, 1 vol. 8vo.; and 'Observations on the History of France,' by Velly, Villaret, and Garnier, 4 vols. 12mo, 1806. Gaillard died in 1806, in consequence of his severe application. His moral character stood very high.

GAINSBOROUGH, an antient market-town and parish situated on the eastern bank of the Trent, in the county of Lincoln, 149 miles N. by W. from London. Gainsborough is noted as being the place where the Danes anchored at the period when the surrounding country was devastated by their sanguinary tyrant Sweyne, and where he was stabbed by an unknown hand when on the point of re-embarking. It is also the birth-place of Simon Patrick, the learned and pious bishop of Ely, who died in 1707. The town is well paved and lighted, and consists principally of one street running parallel to the river, which is here crossed by a fine stone bridge of three elliptical arches. The townhall, wherein the sessions were formerly held, is a substantial brick building, beneath which is the gaol. The living is a vicarage in the diocese of Lincoln, and in the patronage of the bishop of that see, with an annual net income of 529*l.* Gainsborough is advantageously situated both for foreign and inland trade. By means of the Trent, which falls into the Humber about 20 miles below the town, vessels of 200 tons are enabled to come up to the wharfs, and by the Readley, Chesterfield, and other canals a communication is kept up with the interior of the country. The market-day is Tuesday, and the fairs for cattle, &c. are held on Easter-Tuesday and the 20th of October. In 1831 the entire parish, including the hamlets of Morton, East Stockwith, and Walkerith, contained 7535 inhabitants. There is a charity school at which the children of the poor are taught reading, writing, and the elements of arithmetic.

GAINSBOROUGH, THOMAS, born in 1727, at Sudbury, in Suffolk, was one of the most eminent English landscape painters of the last century. His father being a person in narrow circumstances, the education which his son received was very scanty; and it is probable enough that in his boyish days he passed much less time at school than in the woods of Suffolk, where he acquired that relish for the beauties of quiet nature and that intimate acquaintance with them for which his early pictures are so peculiarly distinguished. Having almost from his childhood amused himself with sketching any object that struck his fancy, an old tree, a group of cattle, a shepherd and his dog, &c., he ventured on colouring, and had painted several landscapes before he was twelve years of age, when he was sent to London. There he was for some time with Mr. Gravelot, the engraver, and Hayman, the painter, with whom he did not remain long, but setting up as a portrait-painter, supported himself, till, at the age of nineteen, he married a young lady who had a fortune of 200*l.* per annum. On his marriage he went to Ipswich, where he resided till 1758, when he removed to Bath. Having practised portrait-painting with increasing success, he removed in 1774 to London; and having painted portraits of some of the royal family, which were much admired, he soon acquired extensive practice and proportionate emolument. But though his portraits were much valued at the time as striking likenesses, this was too frequently their only merit: they were often painted in a rough careless manner, in a style of hatching and scumbling entirely his own, producing indeed an effect at a distance, but undetermined and indistinct when viewed near. At times he would take more pains, and show what he could do. But Gainsborough, in fact, considered this loose manner as peculiarly excellent, and was desirous that his pictures in the Exhibition might be so hung as to be within reach of close inspection. With painters his fame rests on his landscapes, and what might be called fancy-pieces, such as the celebrated 'Cottage Door,' now in the collection of the Marquis of Westminster. There is however a wonderful difference between his early and his later performances. In the former every feature is copied from nature in its greatest detail, and yet without stiffness; so that they look like nature itself reflected in a convex mirror. In his latter works striking effect, great breadth, and judicious distribution of light and shade, produce a grand and even a solemn impression. Both have their admirers, as tastes differ; but though he may not deserve to be ranked as some would have him, with Vandyck, Rubens, and Claude, in portrait and in landscape, all will assent to the opinion of Sir Joshua Reynolds—'that if ever this nation should produce genius sufficient to acquire to us the honourable distinction of an English school, the name of Gainsborough will be transmitted to posterity as one of the very first of that rising name.'

Gainsborough died of a cancer in the neck, in August, 1788, in the sixty-first year of his age.

GAIUS, or CAIUS, one of the Roman classical jurists whose works entitle him to a place among the great writers on law, such as Papinian, Paulus, and Ulpian. Nothing is known of the personal history of Gaius beyond the probable fact that he wrote under Antoninus Pius and Aurelius. His works were largely used in the compilation of the 'Digest,' or 'Pandect,' which contains extracts from the writings of Gaius under the following titles:—'Res Cottidianæ sive Aureorum,' (Dig. xl. 9, 10, &c.); 'De Casibus,' (xii. 6, 63, &c.); 'Ad Edictum Ædilium Curulium,' (xxi. 1, 18, &c.); 'Liber ad Edictum Prætoris Urbani,' xl. 12, 6, &c.); 'Ad Edictum Provinciale,' (xiv. 4, 9, &c.), which consisted of thirty books at least; 'Fidei Commissorum,' (xxxii. 1, 14, &c.); 'Formula Hypothecaria,' (xx. 1, 4, &c.); 'Institutiones,' (i. 6, 1, &c.); 'De Verborum Obligationibus,' (xlvi. 1, 70). There are also extracts from several other works of Gaius in the 'Pandect.'

The 'Institutions' of Gaius were probably the earliest attempt to present a sketch of the Roman law in the form of an elementary text-book. This work continued in general use till the compilation of the 'Institutions' which bear the name of Justinian, and which were not only mainly based on the 'Institutions' of Gaius, but, like this earlier work, were divided into four books, with the same general distribution of the subject matter as that adopted by Gaius.

The 'Institutions' of Gaius appear to have been neglected after the promulgation of Justinian's compilation, and were finally lost. All that remained was the detached pieces collected in the 'Digest,' and what could be gathered from the 'Breviarium Alaricianum,' as the code of the Visigoths is sometimes called. But in 1816, Niebuhr discovered a MS. in the library of the chapter of Verona, which he ascertained to be a treatise on Roman law, and which Savigny, founding his opinion on the specimen published by Niebuhr, conjectured to be the 'Institutions' of Gaius.

This conjecture of Savigny was soon fully confirmed, though the MS. has no author's name on it. Goeschen, Bekker, and Hollweg undertook to examine and copy this MS., an edition of which appeared at Berlin in 1820, edited by Goeschen. To form some idea of the labour necessary to decipher this MS., and of the patient perseverance of the scholars who undertook this formidable task, the reader must refer to the report of Goeschen to the Academy of Berlin, November 6, 1817. The MS. consists of one hundred and twenty-seven sheets of parchment, the original writing on which was the four books of the 'Institutions' of Gaius. This original writing had on some pages been washed out, so far as was practicable, and on others scratched out; and the whole, with the exception of two sheets, had been re-written with the epistles of St. Jerome. The lines of the original and of the substituted writing run in the same direction, and often cover one another; a circumstance which considerably increased the difficulty of deciphering the text of Gaius. In addition to this, sixty-three pages had been written on three times: the first writing was the text of Gaius, which had been erased; and the second, which was a theological work, had shared the same fate, to make room for the epistles of St. Jerome.

A second examination of this MS. was made by Bluhme (*Præfatio Novæ Editionis*), and a new edition of the 'Institutions' was published by Goeschen, at Berlin, in 1824, which presents us with an exact copy of the MS. with all its deficiencies, and contains a most copious list of the abbreviations used by the copyist of Gaius.

The discovery of a work, the loss of which had so long been regretted, produced a most lively sensation among continental jurists, and called forth a great number of essays. In England it has yet attracted little attention beyond a superficial notice in the 'Edinburgh Review' (vol. xlviii., p. 385), and an occasional allusion to it elsewhere, though it is undoubtedly one of the most valuable additions that have been made in modern times to our knowledge of Roman Law. The fourth book of the 'Institutions' is particularly useful for the information which it contains on actions and the forms of procedure. The style of Gaius, like that of all the classical Roman jurists, is perspicuous and yet concise.

One of the most useful editions of Gaius is that by Klenze and Böcking (Berlin, 1029), which contains the 'Institutions' of Gaius and Justinian, so arranged as to present a parallelism, and to furnish a proof, if any were yet wanting, that the MS. of Verona is the genuine work of Gaius.

In addition to the references already made, the reader may consult an ingenious essay by Goeschen on the 'Res Quotidianæ,' of Gaius (*Zeitschrift für Geschichtliche Rechtswissenschaft*, Berlin, 1815); Hugo, 'Lehrbuch der Geschichte des Römischen Rechts;' Dupont, 'Disquisit. in Commentarium iv. Instit. Gaii,' &c., Lugd. Bat. 1822.

GALACZ. [MOLDAVIA.]

GALA'GO. [LEMURIDÆ.]

GALANGA, or GALANGAL, is usually supposed to have been introduced by the Arabs, but it was previously mentioned by Ætius. The Arabs call it *Kholingan*, which appears to be derived from the Hindu *Koolinjan*, or Sanscrit *Koolunjuna*, indicating the country whence they derived the root, as well as the people from whom they obtained their information respecting its uses. The plant which yielded this root was long unknown, and it was supposed to be that of a pepper, of an iris, of Acorus Calamus, or to be the Acorus of the antients. Kæmpferia Galanga was so called from its aromatic roots being supposed to be the true Galangal. The tubers of *Cyperus longus* were sometimes substituted, and called *English Galangal*. Two kinds, the large and the small galangal, are described; these are usually considered to be derived from the same plant at different stages of its growth, but Dr. Ainslie, in his 'Materia Indica,' insists upon the greater value of the lesser, as this is warmer and more fragrant, and therefore highly prized in India. It is a native of China, and the plant producing it is unknown. Dr. Ainslie does not prove that it is the Galanga minor of Europe.

The greater Galangal has long been known to be the produce of a Scitamineous plant, the Galanga major of Rumphius (*Herb. Amb.* 5. t. 63), which is the *Alpinia Galanga* of Wildenow, and a native of China and the Malayan Archipelago. It is fully described by Dr. Roxburgh, in his *Flora Indica*, vol. i. p. 28, ed. Wall. The roots, perennial and tuberous, like those of the ginger, were ascertained by Sir Joseph Banks and Dr. Comb to be identical with the Galanga major of the shops. This is cylindrical, often forked, thick as the thumb, reddish brown externally, marked with whitish circular rings, internally lighter coloured, of an agreeable aromatic smell, and a hot spicy taste, like a mixture of pepper and ginger, with some bitterness. The stem is perennial, or at least more durable than those of herbaceous plants; when in flower, about six or seven feet in length; its lower half invested by leafless sheaths. The leaves are two-ranked, lanceolar, from twelve to twenty-four inches long, and from four to six broad. Panicle terminal, crowned with numerous branches, each supporting from two to five pale greenish-white and somewhat fragrant flowers in April and May in Calcutta, where the seeds ripen, though rarely, in November.

Several species of this genus have roots with somewhat similar properties. Thus Alpinia alba and Chinensis are much used by the Malays and Chinese; the former has hence been called Galanga alba of Kœnig; and the latter has an aromatic root with an acrid burning flavour. The fragrant root of *A. nutans* is sometimes brought to England, according to Dr. Roxburgh, for Galanga major. Its leaves, when bruised, have a strong smell of cardamums, and the Cardamomum plant is frequently placed in this genus, but has been described under ELETTARIA.

GALANTHUS, a genus of Amaryllidaceous plants consisting of the Snowdrop and another species. The former plant is a native of subalpine woods in various parts of Europe; the second, which is the G. plicatus of botanists, inhabits the Asiatic provinces of the Russian and Turkish empires.

GALAPAGOS are a group of islands in the Pacific, about 700 miles from the continent of South America, near the equator. They lie between 1° N. lat. and 2° S. lat., and between 89° and 92° W. long., and consist of six larger and seven smaller islands. The largest is Albemarle Island, which is 60 miles in length, and about 15 broad. The highest part is 4000 feet above the sea. Charles Island, now called La Floriana, is 20 miles long from north to south, and about 15 miles wide.

There are few islands in the world whose volcanic origin is more incontestable than that of the Galapagos. They consist of enormous masses of lava, rising abruptly from a fathomless sea. Along the shores nothing but black dismal-looking heaps of broken lava meet the eye; but in the interior, valleys and plains of moderate extent occur, which are covered with shrubs and that kind of cactus which is called prickly pear. This cactus supplies with food the land tortoises, which are called the great elephant-tortoises, their feet being like those of a small elephant. These animals grow to an enormous size, and frequently weigh 300 or 400 pounds. There are also iguanas and innumerable crabs. Pigeons also abound.

The climate is not so hot as would be expected from the geographical position of the islands, which is partly to be ascribed to the elevation of their surface (the settlement on La Floriana being 1000 feet above the level of the sea), and partly to the cold current which sets along the south-south-western side of the group to the north-north-west. The dry season occurs in our summer, when most of the water-pools dry up; but at the setting-in of the rains, in November, they are again filled. Between May and December the thermometer ranges between 52° and 74°, and from January to May between 74° and 84°. Captain Hall found that it rose to 93°, but this may have been the effect of local circumstances.

These islands were long considered as sterile rocks, and were first visited towards the end of the last century by the whalers of the Pacific Ocean, especially for the elephant-tortoises, which were caught in great number, and served the crews for fresh provisions. In 1832 a settlement was formed by one Bilamil, an inhabitant of Guayaquil, who obtained a grant of the island of La Floriana from the government of Ecuador. The inhabitants cultivate bananas, sugar-cane, sweet potatoes, and Indian corn in such quantities, that they can provide with these articles the whalers, who frequently resort to the island. (Captain Basil Hall's *Extracts from a Journal*, &c.; *London Geographical Journal*, vol. vi.; Reynolds's *Voyage of the U. S. frigate Potomac*, &c.)

GALATHE'A (Zoology), GALATHEA-TRIBE, GALATHEIDÆ, a group of Crustaceans corresponding with the genus *Galathea* of Fabricius, and establishing, in the opinion of M. Milne Edwards, a passage between the Anomurous and Macrurous Crustaceans, being more particularly approximated to the *Porcellanæ*. [PORCELLANIDÆ.] Dr. Leach divided the genus established by Fabricius into four: viz. the true *Galatheæ*, *Munidea*, *Grimothea*, and *Æglea*. M. Milne Edwards thinks that three of these genera should be preserved, but agrees with M. Desmarest in coming to the conclusion that the genus *Munidea* has not sufficient characteristics to admit of its adoption in a natural classification. With regard to *Æglea*, M. Milne Edwards considers it as approximating more to the *Porcellanæ* than to the *Galatheæ*, and as occupying a place in the section of the *Anomura*.

The *Galatheidæ*, then, according to the revision of M. Milne Edwards, are thus distinguished. *Carapace* depressed and wide, but still longer than its width, terminating anteriorly by a *rostrum* more or less projecting, which covers the place of the ocular peduncles, and presents on its upper surface many furrows or wrinkles, among which, one deeper than the rest defines the posterior part of the stomachic region. *Antennæ* inserted on the same transversal line; internal antennæ but little elongated, placed under the ocular peduncles, and terminated by two small, multiarticulate, very short filaments; external antennæ with no trace of palpiform appendages at their base, but with a cylindrical peduncle and a long and slender terminal filament. *External Jaw-feet* (pates-mâchoires) always pediform, but varying a little in their conformation. *Sternal plate* (plastron sternal) widening a good deal posteriorly,

and the last thoracic ring ordinarily distinct. Anterior *feet* large and terminated by a well formed claw; those of the three following pairs of limbs rather stout, and terminated by a conical tarsus; fifth pair very slender, and folded above the others in the branchial cavity; these last do not assist the locomotion, and are terminated by a rudimentary hand. *Abdomen* nearly as wide as the thorax, and longer, vaulted above and armed on each side with a row of four or five large teeth formed by the lateral angle of the superior arch of the different rings composing it, and terminated, as in the greater part of the Macrurous Crustaceans, with a large fan-shaped lamelliform fin. The number of abdominal *false feet* varies; in the male there are five pairs, the two first of which are slender and elongated, and the three last are terminated by an oval lamina ciliated on the edge: in the female, the first abdominal ring is without appendages, but the four following segments have each a pair of false feet composed of three joints placed end to end and fringed with hairs for the attachment of the eggs.

Genera. Galathea.

Generic Character.—The whole surface of the *Carapace* covered with transverse furrows fringed with small brush-like hairs. Hepatic regions, in general, well distinguished from the branchial, and occupying with the stomachic region nearly half of the space of the Carapace. *Rostrum* projecting and spiny; *eyes* large and directed downwards; no trace of an orbit. A spine above the insertion of the external antennæ, and two others on the anterior part of the stomachic region. Basilary joint of the *internal antennæ* cylindrical and armed at its anterior extremity with many strong spines; the two following joints slender and nearly as long as the first. Peduncle of the *external antennæ* composed of three small cylindrical joints, the last of which is much smaller than the others. *External Jaw-feet* moderate, the two last joints neither foliaceous nor even enlarged. Anterior feet long and depressed. (Milne Edwards.)

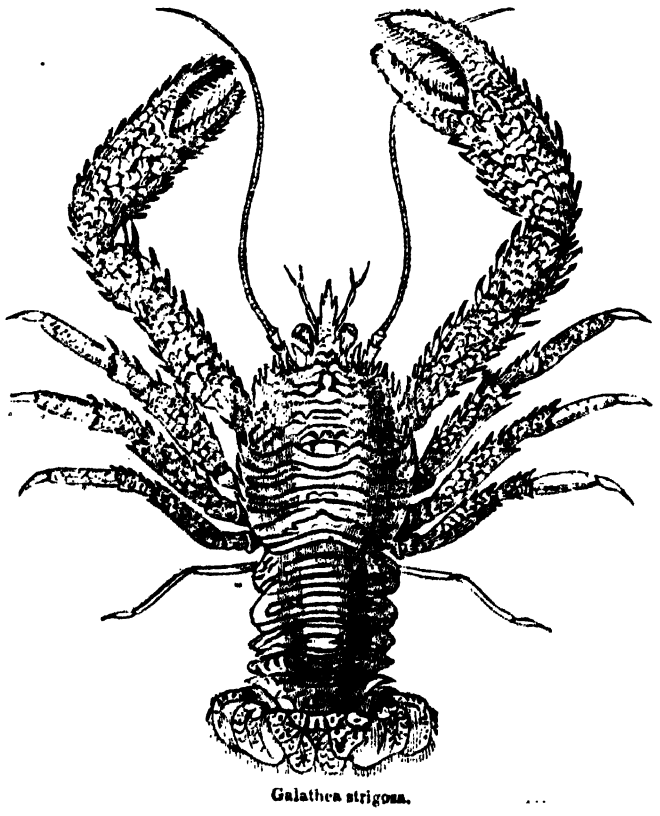
*

Species whose external jaw-feet present a row of teeth on the internal edge of their second joint.

α

Third joint of the external jaw-feet shorter than the second.

Example, *Galathea strigosa*; *Galathea spinigera*, Leach; *Cancer strigosus*, Linn. Description.—Rostrum triangular and armed with seven strong projecting spiniform teeth. Lateral edges of the carapace with strong spiniform teeth.



Galathea strigosa.

Three long spines at the anterior extremity of the first joint of the external antennæ; a great spine under the auditory tubercle, two smaller ones on the first joint of the external antennæ, and one on their second joint. External jaw-feet short, hardly overpassing the rostrum when they are extended, their third joint much shorter than the second, and armed beneath with two strong spines. Anterior feet long, depressed, and very spiny; the hand very large, edged with spines and ornamented above with small piliferous furrows resembling imbricated scales, claws short, large and with a spoon-shaped termination. Feet of the second and third pair of the same length. Abdomen furrowed transversely, but without a spine; the seventh segment a little widened and rather narrower behind than before. Colour reddish, with some blue lines on the carapace. Length about five inches *Locality*, the Mediterranean and the Ocean.

β

Third joint of the external jaw-feet much longer than the second.

Example, *Galathea squamifera*. Locality, the coasts of England and France.

* *

Species whose external jaw-feet have no dentilation on the internal edge of their second joint.

Example, *Galathea Monodon*. Locality, the coasts of Chile.

Grimothea.

Differing but little from *Galathea*, and hardly sufficiently distinct for separation. General form of both essentially the same, but the basilary joint of their internal antennæ is claviform and hardly dentated at its extremity, and the external jaw-feet are very long and have their three last joints enlarged and foliaceous. (Milne Edwards.)

Example, *Grimothea gregaria*.

M. Milne Edwards observes that the Crustacean figured by M. Guérin under the name of *Grimothée sociale* ('Voyage of La Coquille:' Crust., pl. 3. fig. 1) differs from *G. gregaria* in the form of the caudal fin, the middle lamina of which is less than the lateral ones. M. Edwards proposes therefore to name it *Grimothea Duperreii* in honour of the navigator whose voyage made the species known.

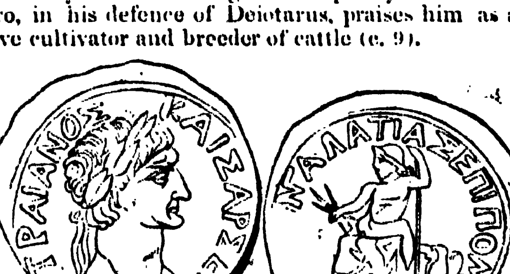
N.B. The student should bear in mind that the term *Galathea* was employed by Bruguières (who died in 1799) to distinguish a genus of Conchifers which M. Rang thinks might as well perhaps be united to *Cyrena*.

M. Desmarest is of opinion that M. Risso's genus *Calypso*, afterwards, according to M. Desmarest, named by M. Risso *Janira* (a designation allotted by Dr. Leach to a genus of *Isopoda*), approximates closely to *Galathea*.

GALATIA, a country of Asia Minor, which originally formed part of Phrygia and Cappadocia. It is difficult to determine its exact boundaries, as they differed at various times. It was bounded on the south by Phrygia and Cappadocia, on the east by Pontus, on the north by Paphlagonia, and on the west by Bithynia. It obtained the name of Galatia from the settlement of a large body of Gauls in this part of Asia. The first horde that appeared in Asia (B.C. 279) formed part of the army with which Brennus invaded Greece. In consequence of some dissensions in the army of Brennus, a considerable number of his troops, under the command of Leonorius and Lutarius, left their countrymen and marched into Thrace; thence they proceeded to Byzantium, and crossed over into Asia at the invitation of Nicomedes king of Bithynia, who was anxious to secure their assistance against his brother Ziboetas. (Livy, xxxviii. 16.) With their aid Nicomedes was successful; but his allies now became his masters, and he, as well as the other monarchs of Asia Minor to the west of Mount Taurus, was exposed for many years to the ravages of these barbarians, and obliged to purchase safety by the payment of tribute. Encouraged by the success of their countrymen, fresh hordes passed over into Asia, and their numbers became so great that Justin informs us (xxv. 2) "that all Asia swarmed with them; and that no Eastern monarchs carried on war without a mercenary army of Gauls." In conformity with this statement, we read of their assisting Ariobarzanes and Mithridates, kings of Pontus (about B.C. 266), against Ptolemy king of Egypt (Clinton's *Fasti Hellenici*, vol. iii. p. 424), and of their supporting Antiochus Hierax in his ambitious wars against his brother Seleucus Callinicus (Seleucus reigned B.C. 246-226). They are also said in the second book of Maccabees (viii. 20) to have advanced as far as Babylon, and

to have been defeated by the Jews. The first check they eceived was from Attalus I. king of Pergamus, who defeated them in a great battle (B.C. 239) and compelled them to settle permanently in that part of Asia which was afterwards called Galatia. (Livy, xxxiii. 21; Polybius, xviii. 24.) Before this time they appear to have had no fixed habitations, but to have wandered over the various provinces of Asia Minor in search of plunder, and to have had the command of the sea-coasts of Bithynia and Paphlagonia; since Pausanias states (i. 18, s. 2) that Attalus forced them to retire from the sea to the country which they inhabited in his time. Though Attalus reduced their power, they still remained independent, and gave Antiochus great assistance in his contest with the Romans. Having thus incurred the enmity of the Roman republic, Cn. Manlius the consul was sent against them with a considerable army, B.C. 189. The particulars of this war, which terminated in the complete defeat of the Galatians, are recorded in Livy (xxxviii. 12-27). From this time they were in reality subject to Rome, though allowed to retain their own native princes. In the war against Mithridates, Deiotarus, originally only a tetrarch of one of the Galatian tribes, greatly assisted the Romans, for which service he was rewarded by the grant of Pontus and Little Armenia, and the title of king by the Roman Senate. [DEIOTARUS.] He was succeeded by Amyntas, according to Strabo (b. xiii.), or by Castor according to Dio (l. xlviii.). At the death of this prince, B.C. 25, Galatia became a Roman province. After the time of Augustus, the boundaries of the province were enlarged, and Paphlagonia was added to it; but in the reign of Constantine it was again reduced to its former limits; and in the time of Theodosius the Great was subdivided into two provinces, *Galatia prima* and *Galatia secunda*, of which Ancyra was the capital of the former, and Pessinus of the latter.

Strabo (b. xii.) informs us that Galatia was inhabited by three tribes of Gauls: the Trocmi, the Tectosages, and the Tolistobogii. Pliny (*Nat. Hist.* v. 42) mentions four tribes: Trocmi, Tectosages, Voturi, and Ambitui. Mannert (*Géographie*, vol. iii., part iii., p. 43) supposes with great probability that Pliny has by mistake given us the names of two of the smaller divisions, especially as he mentions incidentally in the same chapter the name of the Tectosages. Each tribe was subdivided into four parts, and each tribe was governed by a tetrarch, who appointed a judge and an inspector of the army. The power of these twelve tetrarchs was limited by a senate of 300, who assembled at a place called Drynæmetum, and who took cognizance of all capital cases. All other offences were left to the jurisdiction of the tetrarchs and judges. This form of government continued till shortly before the time of Deiotarus. All the tribes spoke the same language, and had the same customs. Though they afterwards spoke Greek in common with the other nations of Asia Minor, yet they had not forgotten their native tongue in the time of Jerome, who informs us (*Prolegomena in Epis. ad Galatas*) that they then spoke the same language as the Treviri. They did not entirely lose their original simplicity of manners, for Cicero, in his defence of Deiotarus, praises him as an extensive cultivator and breeder of cattle (c. 9).



Coin of Galatia, Trajan. Imperial Greek.
British Museum. Actual size. Copper. Weight, 427 grains.

Galatia possessed few towns of importance, with the exception of ANCYRA, Tavium, and Pessinus. Tavium, the capital of the Trocmi, was situate in the north-east part of the province, but soon fell into obscurity. Pessinus, the capital of the Tolistobogii, north-east of the river Sangarius, was a great trading place, with a magnificent temple, sacred to the mother of the gods, who was there worshipped under the name of Agdistis. (Strabo, b. xii.) Pausanias mentions this temple, and also adds that the inhabitants of this town abstained from pork, for which custom he assigns a curious reason (vii. 17). On the river Sangarius in this province was the ancient Gordium, formerly the capital of the Phrygian monarchy, but which had become in the time of Strabo little better than a village. Livy (xxxviii. 18) describes Gordium as a small town in his time, but carrying on an extensive commerce.

Galatia was also called Gallo-Græcia, and its inhabitants Gallo-Græci, from the intermixture of the customs and languages of the Gauls and Greeks in this province.

GALATIANS, ST. PAUL'S EPISTLE TO THE, one of the canonical books of the New Testament. Its authenticity has never been doubted: it was frequently cited by the apostolical and succeeding fathers (Lardner's *Credibility of the Gosp. History*, vol. ii.), and was even admitted by Marcion to a place among the apostolical writings. The date of this epistle is much disputed, some critics supposing it to have been written as early as A.D. 48, and others as late as 58. Two journeys of St. Paul to Galatia are mentioned in the Acts; one in A.D. 50 (Acts xvi. 6); and the other in 55 (Acts xviii. 23). It must have been written shortly after one of these visits, since St. Paul complains (i. 6) 'that they were so *soon* removed from him that called them into the gospel of Christ unto another gospel.' As there is very slight evidence of his having visited Galatia a second time before he wrote this epistle, we may fix the date at A.D. 51 or 52. Hug argues in his 'Introduction' (vol. ii. p. 362, Eng. trans.), that the words, 'Ye know how through infirmity of the flesh I preached the gospel unto you *at the first* (τὸ πρότερον)' (iv. 13), prove that the apostle had visited them twice; in which case we must suppose the Epistle to have been written A.D. 56 or 57. It is stated at the conclusion to have been written from Rome, but this is evidently incorrect.

It appears that shortly after St. Paul had left Galatia, some Judaizing teachers had effected a great change in the churches of that country by teaching the Gentile converts that it was necessary for them to observe the ceremonial law, and submit to the rite of circumcision. They alleged that the other apostles taught this doctrine, and that St. Paul alone differed from them. They argued that the Galatians ought not to rely upon the authority of St. Paul, since he was not an apostle. These individuals were so successful that some of the Galatians appeared to have submitted to circumcision. To counteract these errors St. Paul wrote this epistle, in which he maintains that the authority of the other apostles could not be quoted as superior to his own, since he had received his apostleship from Christ himself, and had on this very subject 'withstood Peter to the face, because he was to be blamed.' (i. ii.) After thus vindicating his apostolical dignity, he argues in the remaining part of the epistle that the law had only been intended as a preparation for Christianity, as a 'schoolmaster to bring men unto Christ, that they might be justified by faith,' and that those who considered the observance of the Jewish law as necessary for salvation deprived themselves of the blessings of the Gospel. He concludes by exhorting them not to use the liberty which the Gospel gave them 'for an occasion to the flesh, but by love to serve one another.' On the undesigned coincidences with the 'Acts,' see Paley's *Horæ Paulinæ*, p. 135-183. (A list of commentators on this epistle is given in Watt's *Biblioth. Britannica*, and in Seiler's *Biblical Hermeneutics*, by Dr. Wright, p. 531. See Michaelis's *Introduction*, vol. iv. p. 8-22; Hug's *Introduction*, vol. ii. p. 361-366; Horne's *Introduction*, vol. iv. p. 369-372.)

GALAXAURA. [PSEUDOZOARIA.]

GALAXY. [MILKY WAY.]

GALBA, SE'RVIUS SU'LPITIUS, born under the reign of Augustus, of a patrician family, served with distinction in Germany, was afterwards proconsul, first in Africa, and afterwards in the Tarraconensis province of Spain, in which office he acquired a reputation for justice and moderation. He was still in Spain when Julius Vindex, the proconsul of Celtic Gaul, rose against Nero: Galba joined Vindex, and Otho, governor of Lusitania, followed his example. The assembled multitudes saluted Galba as emperor and Augustus, but he declared that he was only acting as the lieutenant of the senate and people of Rome, in order to put an end to the disgraceful tyranny of Nero. The Prætorian guards at Rome soon after having revolted against Nero, proclaimed Galba, and the senate acknowledged him as emperor. Galba hastened from Spain to Rome, where he

began by calling to account those favourites of Nero who had enriched themselves by proscriptions and confiscations, and by the senseless prodigality of that prince; but it was found that most of them had already dissipated their ill-gotten wealth. Galba, or rather his confidants who governed him, then proceeded against the purchasers of their property, and confiscations became again the order of the day. At the same time Galba exercised great parsimony in the administration, and endeavoured to enforce a strict discipline among the soldiers, who had been used to the prodigality and licence of the previous reign. The emperor, who was past seventy years of age, soon became the object of popular dislike and ridicule, his favourites were hated, and revolts against him broke out in various quarters, several of which were put down and punished severely. Galba thought of strengthening himself by adopting Piso Licinianus, a young patrician of considerable personal merit, as Cæsar and his successor; upon which Otho, who had expected to be the object of his choice, formed a conspiracy among the guards, who proclaimed him emperor. Galba, unable to walk, caused himself to be carried in a litter, hoping to suppress the mutiny; but at the appearance of Otho's armed partisans his followers left him, and even the litter-bearers threw the old man down, and ran away. Some of the legionaries came up and put Galba to death, after a reign of only seven months, counting from the time of Nero's death, A.D. 68. Galba was seventy-two years of age at the time of his death. He was succeeded by Otho, but only for a short time, as Vitellius superseded him, and Vespasianus soon after superseded Vitellius. (Tacitus, *Histor.* i.—iv.)

Reverses of coins of Galba.

GA'LBANUM. Though this drug is one of those which have been the longest known, the plant which yields it still remains undetermined, though it is stated by old writers to be a native of Syria. The Greek name *chálbane* (χαλβάνη) is evidently the same as the Hebrew *chelbenah*, by which the same substance is supposed to be alluded to in the Book of Exodus. Arabian authors describe it under the name *barzud*. The Persians call it *birzud*, and give *birreja* as its Hindú synonyme. That the same substance is intended, is evident from *khulyan* and *metonyon*, as stated by Dr. Royle (*Illustr. Himal. Bot.* p. 23), being given as its Greek synonymes, which are evident corruptions of *chalbane* and *metopion*, the names of this substance in Dioscorides. The plant yielding this substance is called *kinneh* and *nafeel* by Arabian and Persian authors, by whom it is described as being jointed, thorny, and fragrant. Under the first name it is noticed in the original of Avicenna, but omitted in the Latin translation. D'Herbelot (*Bibl. Orient.*) however states, that the plant yielding galbanum is called *ghiarkust* in Persia. These names are interesting only as showing that both the plant and gum-resin appear to have been familiarly known to both Arabians and Persians, and that therefore the former is probably a native of these countries, though usually stated to be only a native of Syria. But if so, it could hardly have escaped the notice of the numerous travellers who have visited that country.

The plant usually described as yielding this long-known gum-resin is Bubon Galbanum, a native of the Cape of Good Hope, which Hermann described as yielding spontaneously, by incision, a gummy, resinous juice, similar to Galbanum; but Mr. Don has observed that this plant possesses neither the smell nor the taste of Galbanum, but in these particulars agrees better with fennel; and its fruit has no resemblance whatever to that found in the gum. The fruit, commonly called seed, was early ascertained by Lobel to be that of an umbelliferous plant, broad and foliaceous, which he picked out of Galbanum, and, having sowed, obtained a plant, which he has figured under the name of *Ferula galbanifera*. This has been lost or become confounded with other species; but it is probable that it was the plant yielding Galbanum, as Mr. Don has recently obtained fruit in like manner, and something similar, which he has determined to be allied to the genus Siler; but differing in the absence of dorsal resiniferous canals, and the commissure being furnished with only two. The carpels are about nine lines in length and four broad, flat internally and somewhat converse externally. As the plant is still unknown, it is well worthy the investigation of travellers in the East, who might otherwise suppose, from the name, assigned from the seed, having been adopted in the 'London Pharmacopœia,' that the plant was as well known as its product.

Three sorts of GALBANUM are distinguished: 1, galbanum in grains or tears; 2, galbanum in masses; and 3, Persian galbanum. The two former come from Africa, especially from Æthiopia; the third sort from Persia. Galbanum in tears is most likely the spontaneous exudation from the plant; and that in masses, obtained by incisions. The first sort occurs in irregular, generally oblong grains, mostly distinct, but sometimes agglutinated together, about the size of a lentil or small pea, of a colour verging from whitish into yellowish brown, more or less diaphanous, opake, or shining with a resinous lustre. The odour is strongly balsamic, and disagreeable. The taste is resinous, sharp, bitter, and disagreeable. Specific gravity 1·212.

It is partially soluble in alcohol, and the solution, as well as the strong white smoke which is evolved when galbanum is melted in a platinum spoon, reddens litmus paper. It consists chiefly of resin, gum, volatile oil, and a trace of malic acid.

Galbanum in masses consists of irregular pieces of a yellowish or dark brown colour; the odour is stronger than that of the preceding kind, which, in its general characters, it much resembles, except that it can be powdered only during the low temperature of winter. Geiger says that when this variety is pure, it is not to be reckoned inferior to the former. Persian galbanum, being very soft and tenacious, is sent in skins or chests. It often contains many fragments of plants.

Galbanum, like other umbelliferous gum-resins, is antispasmodic, expectorant, and externally rubefacient. It is inferior in power to assafœtida, but usually associated with it in pills and plasters.

GA'LBULA (Zoology). [HALCYONIDÆ; JACAMAR.]

GA'LEA (Zoology). [ECHINIDÆ, vol. ix., p. 259.]

GALENA. [LEAD.]

GALE'NA. [ILLINOIS.]

GALE'NUS, CLAU'DIUS, one of the most celebrated and valuable of the antient medical writers, was born at Pergamum, A.D. 131. The exact time of his death is not known, but as he speaks of Pertinax and Severus as emperors, we may conclude that Suidas (v. Γαληνός) is not far from the truth in stating that he lived to the age of seventy. He was early instructed in the doctrines of the Aristotelian and Platonic philosophy, and appears also to have devoted some time to the study of the peculiar tenets of the other sects; for while yet very young, he wrote commentaries on the Dialectics of the Stoic Chrysippus.

His anatomical and medical studies were commenced under Satyrus, a celebrated anatomist; Stratonicus, a disciple of the Hippocratic school; and Æschrion, a follower of the Empirics. After the death of his father, he travelled to Alexandria, at that time the most famous school of medicine in the world. His studies were so zealously and successfully pursued, that he was publicly invited to return to his native country. At the age of 34, he settled himself in Rome, when his celebrity became so great from the success of his practice, and more especially from his great

knowledge of anatomy, that he quickly drew upon himself the jealousy of all the Roman physicians. At the solicitation of many philosophers and men of rank, he commenced a course of lectures on anatomy; but by the jealousy of his rivals he was quickly compelled to discontinue them, and eventually to leave Rome entirely.

The instruction which Galen had received in the principles of the various sects of medical philosophy, had given him an acquaintance with the peculiar errors of each, and he speaks of them all at times in the language of no measured contempt. The school which was founded by himself may justly merit the title of Eclectic, for its doctrines were a mixture of the philosophy of Plato, of the physics and logic of Aristotle, and of the practical knowledge of Hippocrates. On many occasions he expresses himself strongly on the superiority of theory to mere empiricism; but upon those matters which do not admit of being objects of experience, such as the nature of the soul, he confesses his ignorance and inability to give any plausible explanation.

But in order to form a correct estimate of the merits of this physician, it is necessary for us to mention particularly some of his contributions to medical science. Anatomy was at all times the favourite pursuit of Galen, but it does not appear that he had many opportunities of dissecting the human subject. This we may infer with certainty from the gratification he expresses at having discovered a human skeleton at Alexandria, and having been enabled to make observations on the body of a criminal which had remained without burial. His dissections were principally confined to the apes and lower animals; and it is to this circumstance that many of the errors in his description are referrible: for from the examination of these animals he attempted to infer analogically the structure of the human body. He describes the sternum as consisting of seven pieces instead of eight. He supposes the sacrum to consist of three pieces instead of five, and looks upon the coccyx as a fourth, whereas it is a distinct bone in men till twenty or twenty-five, and in women as late as forty-five.

His descriptions of the muscles appear to be more generally correct. He described for the first time two of the muscles of the jaws, and two which move the shoulder. In addition to these he discovered the popliteal muscles and the platysma myoides. He denied the muscular texture of the heart on account of the complicated nature of its functions, but he gave a good description of its transverse fibres and its general structure. The knowledge of the vascular system which Galen possessed does not appear to have been greater or more accurate than that of his predecessors. He supposed the veins to originate in the liver, and the arteries to take their rise from the heart. He likewise showed by experiment, in opposition to Erasistratus, that the arteries contained blood, and not merely the animal spirits, as that physician maintained. He had observed the structure and use of the valves of the heart, and, arguing from their evident intention, concluded that a portion of the blood passed with the animal spirits from the pulmonary artery into the pulmonary vein, and so to the left side of the heart. He was also aware of the connection between the veins and arteries by means of the capillary vessels. The existence of the ductus arteriosus and foramen ovale during the stage of fœtal life was not unknown to him, and he had also noticed the changes which they undergo after birth.

Galen understood generally the distinction between nerves of sensation and nerves of motion, but his knowledge upon this point does not appear to have been great; for he supposed that the former proceeded only from the brain, and that the latter had their origin exclusively in the spinal marrow. This opinion is the more remarkable, as he himself describes the third pair of cerebral nerves, or principal motor nerve of the eye. In his description of the cerebral nerves, he notices the olfactory, though somewhat indistinctly, the optic, the third pair, two branches of the fifth, the two divisions of the seventh pair, and some branches of the par vagum and hypoglossal nerves, but he appears to have confounded these together very much in his description. He detected the mistake of those anatomists who thought there was an entire crossing of the optic nerves, but fell himself into the error of supposing that no decussation at all takes place.

In order to form correct physiological views, it is necessary to employ many and varied experiments, and to modify them in different ways, that we may be able to satisfy the numerous conditions which every problem in physiology presents. To this mode of inquiry Galen sometimes had recourse, and it were to be wished that he had more frequently made use of it. To prove the dependence of muscular motion upon nervous influence, he divided the nerves which supply the muscles of the shoulder, and found that after the division all power of motion ceased. But he does not seem to have noticed that the nervous influence is only one of the many stimuli which call the muscles into action. As he considered the heart to be devoid of nerves, he might have avoided this error, had he not fortified himself against the truth, by assuming that its structure is not muscular. He also deprived animals of their voice by dividing the intercostal muscles, by tying the recurrent nerve, or by injuring the spinal cord. In theoretical physiology his arrangement of the vital phenomena deserves to be particularly recorded, as it forms the groundwork of all the classifications which have since been proposed. It is founded upon the essential differences observed in the functions themselves. Observing that some of them cannot be interrupted without the destruction of life, and for the most part are unconsciously performed, whilst another class may be suspended without injury, are accompanied by sensation, and subject to the power of the will, he divided the functions into three great classes. The vital functions are those whose continuance is essential to life; the animal are those which are perceived, and for the most part are subject to the will; whilst the natural are performed without consciousness or control. He then assumed certain abstract principles upon which these functions were supposed to depend. He conceived the first to have their seat in the heart, the second in the brain, and the third in the liver. Thus the pulsations of the heart are produced by the vital forces, and these are communicated to the arteries by the intervention of the *pneuma*—this is the more subtle part of the air, which is taken in by respiration, and conveyed from the lungs to the left side of the heart, and from thence to the different parts of the body. In the brain the pneuma forms the medium by which impressions from external objects are conveyed to the common sensorium. The same principle is applied to the explanation of the natural functions also. Observing that these forces are not sufficient for the explanation of the different vital phenomena, Galen had recourse to the doctrine of elements, of which, after the example of Aristotle, and before him Plato in the 'Timæus,' he admits four, and from the mixture of these deduces the secondary qualities. It may be worth while to observe how he employs this hypothesis in his treatise 'De tuendâ Valetudine' (Ed. Johan. Caii. Basil, ap. Froben. 1549), in the explanation of the phenomena of health and disease. The injurious influences to which animal bodies are liable are of two kinds: innate or necessary, and acquired. The former depend upon their original constitution. They are formed of two substances: the blood, which is the material (ὕλη); and the semen, the formative principle. These are composed of the same general elements, 'hot, cold, moist, and dry, four champions fierce,' or, to express them in their essences instead of their qualities, fire, air, water, and earth. Their differences depend upon the proportions in which these elements enter into their composition. Thus in the semen the fiery and aeriform essences predominate; in the blood, the watery and earthy; and in the blood the hot is superior to the cold, and the moist to dry. The semen again is drier than the blood, but yet upon the whole is of a moist nature: so that in the original formation of the body there is a predominance of the moist principle. After birth therefore there is a necessity for an increase of the dry principle. This is obtained not from the earth itself, but through the medium of fire. From the increasing influence of this principle, the changes which take place in the body during life are to be explained: as for instance, the softness and flexibility of the limbs in childhood compared with their rigidity in old-age. By eating and drinking we obtain a fresh supply of the dry and moist principles. By respiration and the pulsations of the heart, a due supply of the cold and hot principles is kept up. But as they cannot be obtained in a fit state for the different uses of the animal economy, organs are necessary to digest, separate, and remove the unsuitable portions.

Health consists in the perfect and harmonious admixture of these various elements. But we must assume, in addition, that the body is free from pain, and that there is no obstacle to the due performance of the functions. From this idea of health we may easily form the conception of

disease. It is that state of body in which the functions are in any way interrupted. It depends upon some disproportion in the constituent elements, or some unnatural condition of the organs. The causes of disease are divided by Galen into occasional and predisposing. The latter are supposed to depend upon some degeneration of the humours. This degeneration was called by him a putrefaction. Thus the quotidian fever is referred to putrefaction of the mucus; tertian, to that of the yellow bile; and quartan, to that of the black bile—this last humour being slow of motion, and requiring a greater time for the completion of the paroxysm. It was upon this theory of the putrefaction of the humours that the practice of physicians was founded for centuries after the death of Galen, and their remedies were directed to the expulsion of the supposed offending matter. Inflammation depends, according to Galen, upon the passage of the blood into those parts which, in their normal condition, do not contain it. If the blood be accompanied by the spirits, the inflammation is spirituous: if the blood penetrates alone, it is phlegmonous. Erysipelatous inflammation is caused by the admixture of bile; œdematous, by that of mucus; and schirrous, by the addition of black bile. The same divisions of inflammation are still retained by systematic writers, but we are content to abstain from referring them to these assumed causes.

The reputation of Galen was established upon the general reception which his theories met with; and his passion for theorizing was so great that he has left us but few good descriptions of disease. In these his principal object seems to have been to display his own talent for prognosis. From a character like this we are not to expect much information in the application of particular remedies, but the general principles which he lays down in respect to indications of treatment are worthy of notice. He directs us to draw our indications especially from the nature of the disease; but if this be undiscovered, from the influence of the seasons and the state of the atmosphere, from the constitution of the patient, his manner of living, or his strength, and in some few instances, from the accession of the disease. He is said to have occasionally performed surgical operations, but during his stay in Rome he commonly refused to do so, in compliance with the custom of the Roman physicians.

The unbounded influence which the authority of this great and learned physician exercised over the minds of his successors, unquestionably contributed to retard the progress of medicine. For while physicians were occupied in the study of his works, and in vain attempts to reconcile the phenomena of nature with the dicta of their master, they had little time and less inclination to interrogate Nature herself, and pursue the study of medicine in those fields in which alone it can be followed with success.

Galen was a most voluminous writer. Though many of his works are said to have been burnt in his house at Rome, and others in the course of time have been lost, there are still extant one hundred and thirty-seven treatises and fragments of treatises, of which eighty-two are considered undoubtedly genuine. From thirty to fifty treatises are still in MS.; and one hundred and sixty-eight are mentioned as the ascertained number of those that are lost. The writings of Galen are valuable, not only for the history of medicine, but the great variety of miscellaneous matter which they contain.

Numerous editions of his works have been published, and several Latin translations since the discovery of printing. Five Latin editions of the collected works of Galen were published before the Greek text: the first Latin edition is that by Bonardus, Venice, 1490, 2 vols., fol. His 'Historia Philosophica' was printed by Aldus in 1497, together some treatises of Aristotle and Theophrastus; and in 1525 the same printer published the first complete edition of the Greek text at Venice, in 5 vols. fol., which was edited by And. and Fr. Asulanus, and was dedicated to Clement the Seventh. The text of this edition was by no means correct; but the impressions on large paper are scarce and valuable. An edition was published at Basle, 1562, in 4 vols. folio, with prolegomena, by the naturalist Gesner. His treatises, 'De Methodo Medendi,' 'De Naturali Facultate,' 'De Sanitate Tuendâ,' were translated by our countryman Linacre, and an edition of his treatise, 'De Sanitate Tuendâ,' and of some other works, was published by Caius. More recently an edition in Greek and Latin has been published by C. G. Kühn (19 vols. 8vo., Lipsiæ, 1821-1830). Most of the writings of Galen exist also in Arabic, and some in Hebrew translations. The reputation of this great writer was for a long time as unbounded and his authority as absolute among the Arabs as among the physicians of Europe.

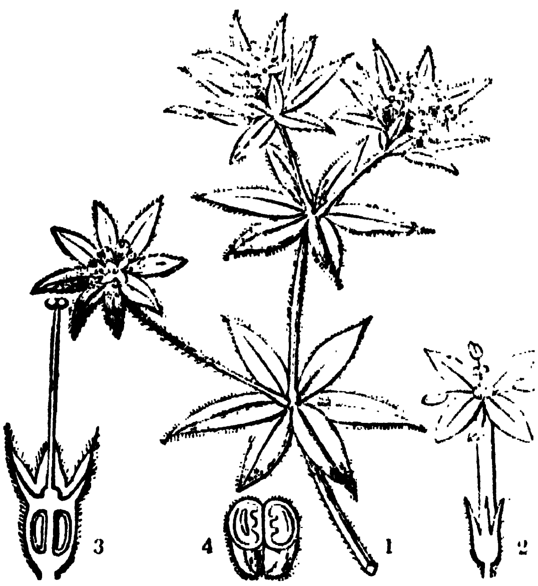
GALIA'CEÆ, a natural order of Exogenous plants called Stellatæ by Linnæus, and merged in Cinchonaceæ by the school of Jussieu. It consists of herbaceous, usually square-stemmed plants, with a scabrous surface, verticillate leaves, and monopetalous flowers with an inferior didymous fruit enclosing a couple of seeds containing an embryo lying in a great quantity of horny albumen. Some yield a dyeing substance in their roots, as the various species of Madder, but the greater part are useless weeds. One of our common British species of Galium, viz., G. verum, is astringent, and was formerly used by farmers to curdle milk.



1, Sherardia arvensis; 2, a perfect flower, magnified; 3, a vertical section of the same, without the corolla; 4, a transverse section of a ripe fruit.

GALIA'NI, FERDINANDO, was born at Chieti, in the Abruzzo, in 1728, and studied at Naples, where he first attracted attention by some humorous compositions which he published under an assumed name, to ridicule certain pedantic academicians ('Componimenti varii per la morte di Domenico Jannaccone carnefice della Gran Corte della Vicaria,' 1749). In the following year his important work, 'Della Moneta,' on the 'coin,' or 'currency,' was also published under an assumed name. In this work he established the principle, which was then far from being acknowledged, that money is a merchandize, and that its value and interest ought to be left free like other goods. He contended also that abundance of money and consequent high prices are not an evil, as was supposed by many, and that in countries where low prices prevail the people are generally most miserable. This work produced a great sensation on the Continent, and especially at Naples, where the government adopted its principles, and left the trade in bullion free. It is generally believed that Bartolommeo Intieri and the Marquis Rinuccini, two Tuscan economists of that time, furnished Galiani, who was then a young man scarcely twenty-one years of age, with their ideas on the subject, which Galiani extended and produced in a readable shape. He published a second edition of this work, 30 years after, in 1780, with additions. In the 1st book he examines the intrinsic value of the precious metals, independent of their use as currency; in the second he treats of the use of a metallic currency as a

medium of exchange; and in the third he discusses the relative value of the three metals used for coin, the conventional value of the coined currency of a country in relation to the prices of goods, and the occasional expedient adopted by some governments to raise the value of the currency, as the Romans did after the first Punic war, and as Louis XIV. did in France.

In 1759 Galiani was sent to Paris as secretary of legation, and his vivacity, wit and repartee rendered him a favourite among the fashionable and literary coteries of that capital. He remained in Paris several years, visited England and Holland, and on his return to France wrote his 'Dialogues sur le Commerce des Blés,' which was his second work on political economy. He did not publish this essay himself, but left the MS. in the hands of Diderot, who had it printed in 1670. The French economists were then divided into two parties, one of which advocated a free trade in corn, and the other was opposed to it. An edict, published in 1764, permitting the free exportation of corn, was followed by a rise of prices and a scarcity, which by some were considered as the effects of that measure, whilst others denied the inference. Galiani supported neither of the two systems absolutely: he contended that the laws concerning the corn-trade must vary according to the situation of various states, the nature and cultivation of the respective soils, the relative position of their corn districts or provinces, and also the form of their governments. In a letter to Suard, dated 1770, he explains himself more clearly on this last topic, saying, 'that under a despotic government a free exportation of corn might prove dangerous, as it might be followed by a famine, which would rouse the people against its rulers; that in a democracy the same freedom is a natural result of the political institutions; whilst in mixed and temperate governments the freedom of the corn-trade must be modified by circumstances.' Galiani censured the free-exportation edict of 1764, and he proposed instead of it certain duties on the exportation of corn, and a lesser duty on the exportation of flour, and a duty likewise on the importation of foreign corn. He notices in his work the small manufacturing states with little territory, like Geneva, and surrounded by powerful and occasionally hostile neighbours, in which he thinks well-stored granaries are as necessary as in a garrison-town; and the states with a territory unproductive in corn, such as Genoa, in which he contends that the corn-trade ought to be perfectly free.

On his return to Naples, Galiani was appointed by the king to the Board of Trade, and afterwards to the Board of Finances, and to the superintendence of the crown domains. His health, naturally weak, suffered from constant application, and he died in October, 1787, at the age of 59 years. He left in MS. a commentary or series of disquisitions on the life and character of Horace and the spirit of his poems, parts of which he showed to several of his friends, who spoke highly of the work, extracts of which are found in the *Correspondence de Galiani avec Madame d'Epinay*, Paris, 1818; in the notes to the *Traduzione d'Orazio di T. Gargallo*, Naples, 1820; in the *Vita dell' abate Ferdinando Galiani, scritta da Luigi Diodati*, Naples, 1788; and in the *Mélanges de l'abbé Suard, tirés de la Gazette littéraire d'Europe*: see also Ugoni, *della Letteratura Italiana*, vol. ii., art. 'Galiani.'

GALICIA, the Kingdom of, is the north-eastern province of the Austrian dominions, and lies between 47° 10′ and 50° 50′ N. lat., and 18° 54′ and 26° 37′ E. long. It includes the country formerly called the Buckowine, and is bounded on the north by the republic of Cracow, Poland, and Russia; on the east by Russia; on the south-east by Moldavia; on the south and south-west by Transylvania and Hungary; and on the west by Hungary, Austrian Silesia, and Prussian Silesia. Galicia derives its name from the former principality of Haliczia or Galiczia, which, together with a considerable portion of Red Russia, once formed part of Hungary, but was incorporated with Poland in the year 1374. Its antient connexion with Hungary served as a pretext to the Empress Maria Theresa, in 1772, when Poland was enfeebled by intestine divisions, to claim its restoration; a claim which the Poles were forced to concede by the treaty of the 18th September, 1773, in consequence of which that part of the republic, now termed Galicia, was surrendered to Austria, and annexed to its dominions under the name of the kingdom of Galicia and Lodomeria. Its area is variously computed; but that of the Austrian quarter-master-general's department, which states it to be 32,508 square miles, is considered the most accurate. Liesganig however, who completed his triangular survey in 1821, estimates it at 32,949 square miles. The population rose from 3,695,285 in 1816 to 4,293,488 in 1825; and from the last numbers to 4,548,334 in 1834. The present population is estimated at nearly 4,600,000.

Galicia spreads out, in its whole length on the northern side of the Carpathian mountains, into extensive plains: those mountains extend their arms deep into the kingdom, and on the west, the Beskide branch of them stretches as far as the banks of the Vistula, rising almost abruptly out of the lowlands into heights of 2000, and sometimes of 4600 feet. The most elevated summit in this quarter is the "Babia Gora," (Women's Mount), which Staszic estimates at 5410, and Hacquet at 5850 feet above the level of the sea. In the south-west, the Patra or central range of the Carpathians, with their peaked summits and desolate naked aspect, rise to still greater elevations; the great Kryvan to about 8300, and the Rohicz to 7230 feet. The branches of this range penetrate much deeper into the country than those of the Beskides. The Buckowine, now the circle o Czernovitz, is covered with offsets of the Carpathians, and is altogether a mountain region. The mountains are ful. of small lakes, which are here called Sav, Plesse, or "Eyes of the Sea;" the largest of them, which lies to the north of the Great Kryvan, is called the Fish Lake; it is at an elevation of about 4550 feet above the level of the sea, but does not exceed 1600 paces in length, or 500 feet in breadth; it has a depth of 192 feet, and forms an almost perfect oval.

The northern part of Galicia is an extensive plain, in some parts intersected by low ranges of hills; and in the western part also a dead level begins at Skavina on the right bank of the Vistula, and varying in width, extends to the banks of the San. The soil of the plains consists almost universally of loam and sand; the most remarkable accumulation of the latter is in what is called the Sand Mountain (Sandberg) near Lemberg.

The rivers of the western part of the kingdom of Galicia belong to the basin of the Vistula; and those of the eastern, to the basins of the Danube and the Dniester. The Vistula forms the western boundary next to Poland for about 180 miles, flowing north-eastwards from the spot where Austrian and Prussian Silesia and Galicia converge to a point, and quitting the kingdom at Popowiecze, a village opposite Zavichost at its northern extremity; this river increases in breadth along this frontier-line from about 120 to nearly 200 paces, and has a rapid current until below Cracow, the difference in the elevation of its bed from the point just mentioned and that city being about 200 feet. The tributaries of the Vistula, on the side of Galicia, are the Dunayec or Danayez, which flows down from the Carpathians, is navigable in the low country, receives the Poprad, also a navigable stream, and other rivers in its course, chiefly northwards, through the circles of Sandecz, Bochnia, and Tarnof, and falls into the Vistula near Novopole, opposite Opatoviec, after a course of about 105 miles. This river, like all those which flow from the Carpathians, overflows its banks in rainy seasons, does much damage and is dangerous to navigate. The Wysloka is formed at Yaslo out of the junction of the Dembowka, Ropa, and Yasielka, flows through the circles of Yaslo and Tarnof, and after a northern course of about 70 miles, joins the Vistula near the village of Ostróf, in the north of Galicia. The San or Saan, the most important tributary of the Vistula in this quarter, rises in the south-western extremity of the circle of Sambor near Sianki, a village on one of the most northerly declivities of the Carpathians, takes a north-westerly direction to Sanok and Bynof, whence it runs eastwards to the town of Przemysl, and thence flows north-westwards through a low country past Yaroslaf until it falls into the Vistula near Lapiszof. Its whole length is about 180 miles, and its chief tributaries are the Wyslek and Tanef. The Bug, which has its efflux in the Vistula also, does not become a considerable stream until it has quitted Galicia; it rises near Galigory to the east of Lemberg, flows westwards when above the latitude of that town, and before it reaches Busk turns northwards and afterwards north-westwards, and leaving Galicia below Sokal, enters Poland. The Dniester, another of the considerable rivers in this kingdom, through which it flows for a distance of about 310 miles, has its source in the Carpathians in the western part of the circle of Sambor, winds through

that circle, Brzezany, Stry, Stanislavof, and Kolomea, and having formed the boundary-line between Galicia and Russia from Czortkof to Orkop beyond Czernovitz, enters the Russian territory. Eastern Galicia has three other large rivers: the Pruth, which rises in the Carpathians within the circle of Stanislavof, flows through that circle as well as Kolomea and Czernovitz in the Buckowine, and passes over into Moldavia below Pentuluy; the Sered, which has its source near Pursuka and leaves the Buckowine below Sereth; and the Moldava, which rises in the circle of Czernovitz and soon afterwards quits the Buckowine, whence it enters Moldavia. The south-eastern districts of Galicia are also watered by the Golden Bistriza, a tributary of the Sereth. There are no canals. According to an enumeration made some years ago, the mineral springs consisted of 11 sulphuretted springs, 12 chalybeate, and 6 acidulous. The most frequented are the chalybeate waters of Krynieza, and the sulphuretted springs of Sklo, Lubien, and Konopkofski.

The climate of Galicia is colder than that of any other possession of Austria, in consequence of the proximity of the Carpathians. The summer is generally short, and the grape never ripens: the winter is very severe for six months at least, and it is not uncommon to see deep snow lying in the middle of April, or an oat-crop buried by the snow, in the vicinity of the Beskide and other Carpathian mountains. The moist and swampy plains in the northern part of the kingdom render that quarter also very chilly and raw.

The soil is of a very varied character. In the neighbourhood of the Carpathians, where sterile rocks or cold clay abound, the husbandman has difficulty in raising even sufficient barley, oats, and potatoes, for his own consumption. But towards the plains, the soil becomes richer and more productive: the most fertile parts are those perhaps about Yaroslaf, such districts in the circle of Zloczof where limestone forms the substratum, the greater portion of the circles of Stanislavof and Kolomea, and the newly cleared lands in the Buckowine. In many parts the soil is so light, that the grass, underwood, and even trees, quickly wither under the heat of the sun.

Galicia abounds in sandstone, granite, sand of a very superior grain, quartz, slate, yellow and common clay, potter's earth, yellow ochre, marble, gypsum, &c. Mountain crystals, agates, jaspers, ordinary opal, alabaster, &c., are found in several spots. The Carpathians are rich in metals, particularly iron, which is found along the whole line of the Carpathians, from the circle of Sandecz to the frontiers of the Buckowine; but the produce does not exceed more than fifteen or, at the utmost, eighteen pounds of metal in every hundred-weight of ore. Bog-iron likewise is met with in the circles of Stry and Zolkief. Gold obtained in small quantities in the circle of Sandec, and gold-dust in the vicinity of Kirlibaba. Veins of silver are found in the lead of Mount Dudul, near that place, and it is also extracted from the calamine obtained near Truska wicze. Poszorita, in the Buckowine, produces good copper ores in the proportion of three, and sometimes five pounds per hundred-weight of mica slate. Native sulphur occurs at Svoszovice, in the circle of Bochnia, and Sklo, in that of Przemysl. Coal is found near Moszyn, Kuty, and Skwarczva. The northern side of the Carpathians contains enormous masses of rock-salt, and the country is full of salt-springs, especially the Buckowine.

The population of Galicia are indolent and ignorant, oppressed by the Fröhndienste (services), which for Galicia alone amount to 31,246,464 days in the year, and the system of husbandry is lamentably defective and imperfect. Independently of the Buckowine, the land available for useful purposes is about 16,394,900 acres; but including that province the quantity converted to use is not more than about 6,211,900 acres in arable land; garden ground, 395,780; fallows, 97,970; converted into ponds, &c., 131,650; meadow-land, 1,876,940; and employed for feeding sheep, cattle, &c., 1,682,360; amounting altogether to 10,396,600 acres, to which must be added 4,998,870 of forest and woodland. The husbandry of Galicia is in a low state; the farmer's waggons are made without iron, his horses are never or seldom used at the plough, and he can scarcely afford to lay manure on his ground. The principal grain produced is wheat, rye, oats, and barley, and the yearly growth is estimated at about 7,200,000 quarters of corn, of which about 1,560,000 quarters are of rye; 2,071,000 of barley; 2,900,000 of oats; 670,000 of wheat, and 22,220 of maize. The crop of hay is said to be about 973,000 tons. Rye, buckwheat, pease and beans, potatoes and other common vegetables, succory, clover, flax and hemp, tobacco, aniseed, rape and other seed for making oil, a few hops, &c. are also grown. The supply of fruit is very scanty. The forests consist principally of pine-wood, and there are large tracts of underwood. The beech was formerly much more abundant on the Carpathians than at the present day, otherwise the Buckowine. from 'buk,' which signifies the red beech, would scarcely have been the patronymic of that province. In some parts the oak attains to a majestic growth. Tar and potashes are made in considerable quantities.

The population has increased since the year 1776, when it amounted to 2,480,885, to its present amount of nearly 4,600,000. The cholera alone in 1831 carried off 96,081 individuals, which is upwards of 2 in every 100 souls. In 1823 the number of deaths was 106,929; in 1829, 148,240; and in 1830, 155,155. Among the latter were those of 3758 persons between the ages of 80 and 100, and 220 above the age of 100. Of the inhabitants about 2,900,000 are of Polish descent, chiefly located in the Western provinces, and 1,900,000 are Ruthenes or Russniaks, a rude, uncivilized race of men, who have spread into the centre of Russia, and are also numerous on the Hungarian side of the Carpathians: they inhabit the circles of Galicia east of the San. The remaining part of the population consists of about 270,000 Moldavians in the Buckowine, 250,000 Jews, who are scattered throughout the kingdom, and a mixed race of Germans, Hungarians, &c.

The majority of the inhabitants are Roman Catholics: there are besides about 1,800,000 who conform partially to the rites of the Roman Catholic church, 270,000 Greek non-conformists, 4000 Armenians, and 5000 Protestants. The Roman Catholics are in ecclesiastical matters in charge of the Archbishop of Lemberg and the bishops of Przemysl and Tarnof. Their dioceses contain 734 benefices, 38 monasteries, 13 nunneries, and a college of Jesuits. The Armenians, though so few in number, have an archbishop at Lemberg, and compose 8 cures of souls. The Græco-Catholics, mostly Russniaks, have also their own archbishop at Lemberg, and a bishop at Przemysl, and their establishment consists of 1488 benefices, 14 monasteries, and 3 nunneries. The Greeks, wholly Moldavians, are under a Greek bishop at Czernovitz in the Buckowine, and compose 274 cures of souls: they have 3 monasteries. The Protestants are under a superintendent at Lemberg.

The number of benevolent institutions is considerable, and comprises eighteen Christian and three Jewish hospitals or asylums for the sick or diseased, a hospital of the Benevolent Brothers, six hospitals conducted by the Benevolent Sisterhood, 312 infirmaries and refuges for the indigent, and twenty-seven poorhous

The government of Galicia is on the same footing as that of the other hereditary possessions of Austria. The highe authority in civil affairs is the Board of Provincial Administration at Lemberg (*das Landes Gubernium*), to which the whole nineteen circles of the kingdom are subordinate. The court of appeal and chief criminal court are in the same town, where also are the head-quarters of the commander-in-chief for Galicia.

The scholastic establishments are very inadequate to provide for the general education of the people. The whole number scarcely amounts to 1400, among which are a university and an academy at Lemberg, three philosophical seminaries at Przemysl, Czernovitz, and Tarnopol, thirteen gymnasia, attended by about 1400 pupils, two schools for merchants' sons, mechanics, &c., at Lemberg and Brody, a normal school at Lemberg, thirty-one head national schools, 1303 parochial and twenty-two girls' schools. It has been calculated that not more than one in every eight children capable of receiving instruction attends any school.

There are seventy-two public establishments for the propagation of improved races of horses and military haras at Radantz in the Buckowine, and Olchowek in the circle of Sanok. The best native horses of the Polish breed are bred in the western circles. The increase has been considerable throughout Galicia, for in 1810, the stock was 214,962; in 1823, 407,662; and in 1830, 497,808. Large droves of horned cattle are fed, the finest being brought from Moldavia: in 1823, the stock was 499,226 oxen and bullocks, and 926,569 cows; and in 1830, 562,865 and 988,332.

Much has been done towards improving the race of sheep, and Galicia now produces some fine wools; the stock was 381,101 in 1810; 653,429 in 1823; and 812,412 in 1830. In the eastern districts especially much honey and wax are made; the red wax of the Buckowine is in great repute. The rivers and small lakes, and ponds, the last of which occupy an area of nearly 206 square miles, are well supplied with fish. The bear, wolf, fox, beaver, roebuck, stag, lynx, marmot, eagle, vulture, swan, heron, wild goose, squirrel and hare are the principal wild animals.

The mining industry of Galicia is chiefly confined to iron and salt. Silver, copper, and lead are the product of the Buckowine: of silver, the produce of Kirlibaba is about 500 marks annually, and of lead in combination with a small portion of silver, about thirty-three tons. The copper-mines of Poszorita yield about fifty tons of metal per annum. The iron-mines in the Carpathians, which comprise 271 shafts, do not yield more than about 2700 tons of metal. The mountains of Galicia abound in rock-salt. The mines of Wieliczka are of great magnitude and well known, and produce four-fifths of the whole quantity raised; the remainder is obtained chiefly from the mines of Bochnia. There has been a great decrease in the annual produce of late years; it was 53,300 tons twenty years ago, and at present it is not more than 42,500. A fine kitchen-salt is made from the saline springs in the eastern parts of the kingdom: there are twenty-two works, producing about 15,200 tons. The quantity exported is about 32,000 tons. A very small quantity of coal is raised at Myszyn, in the circle of Kolomea, and the sulphur-pits at Svoszovice produce about [illegible] tons of pure sulphur yearly. Mineral pitch is distilled into naphtha at the government works in the circles of Sambor, Kolomea, and Stanislavof, to the extent of about 70,000 gallons per annum.

The manufactures of Galicia are gradually extending, though they are still on a confined scale. The country people in general make the materials for their clothing. The spinning and weaving of flax and hemp give employment to thousands. They manufacture very coarse and durable linen, and in some parts a few fine cloths, damask and table linen, &c. The whole number of looms thus employed is about 4600. The cotton manufacture is inconsiderable. Much woollen yarn is spun, both by hand and machinery; and there are small manufactures of coarse woollens in all parts: the finer sorts are made at Biala, Lipnik, Mikulince, Plotycze, and Zalosce. There are 12 paper-mills, but their produce is of inferior quality. Ship-building is carried on principally in the circles of Przemysl and Reszof: the produce of deals, staves, &c. is considerable; and great quantities of utensils, &c. in wood are made. Brandy is manufactured on almost every large estate; the Jews in particular are considerable distillers, and have upwards of 2000 stills at work. Much tobacco and some beet-root sugar are manufactured. Leather employs many hands; but the production of iron, copper, and other metallic articles is limited. Potter's ware, earthenware, and ordinary china, glass, and flints may be added to this enumeration.

The foreign trade of Galicia is very limited, a circumstance owing to the position of the country, the want of enterprise and capital, and the difficulty of navigating the rivers. The lines of communication by land, which are the principal channels of internal intercourse, are in the hands of Jewish carriers. The exports consist of cattle, skins and hides, wool, grain, salt, timber, potashes, aniseed, horses, &c., and the imports of raw materials from Hungary, Poland, Russia, Turkey, &c., and of wines and manufactured goods and colonial produce.

Galicia contains 19 *circles*, 95 *towns*, 194 *market-towns and villages*, 6050 *villages and hamlets, and about* 660,000 *houses.*

Circles.	Area: sq. ml.	Towns.	Market-Towns and Villages.	Villages, &c.	Population. 1830.	Chief Towns.

GALICIA, a province of Spain, situated at the north-west extremity of the peninsula, is bounded on the north by the Bay of Biscay, on the west by the Atlantic Ocean, on the south by Portugal, and on the east by the Spanish provinces of Asturias and Leon. Its greatest length from north to south is about 125 miles, and its greatest breadth about 120. Its area may be reckoned at about 15,000 square miles, and its population is vaguely calculated at above one million and a half; but there are no authentic returns, as Miñano himself observes. The country is mountainous, being covered by several offsets of the Asturian chain, one of which runs westward towards Cape Finisterre, and another runs to the south-west along the right bank of the Miño, dividing the waters of that river from those of the Ulla and the Tambro, and reaches the coast of the Atlantic south of Vigo; whilst a third ridge, farther to the east, runs nearly due south, dividing the waters which flow into the Miño from those which run into the Douro, and extends into Portugal. The principal rivers are—1. The Miño, which rises in the mountains of Mondoñedo, in the north-east part of the province, flows southwards by Lugo and Orense, and receives the Sil, which comes from the mountains of Astorga; on touching the frontiers of Portugal it turns westwards, and forms the boundary between Galicia and the Portuguese province of Entre Douro e Minho, after which it passes by Tuy, and enters the Atlantic in 41° 50′ N. lat. 2. The Tambro, which rises in the mountains north of Sant Iago de Compostela, and flows south-west into the Atlantic. 3. The Ulla, which rises in the mountains in the centre of the province: and flowing westwards, enters the Atlantic south of the Tambro. 4. The Lima, which rises in the mountains south-east of Orense, and flowing south-west, enters Portugal near Lindoso. The principal products of Galicia are wine, fruits, flax, wheat, barley, maize: good pastures, which feed a vast quantity of cattle; and abundance of chesnuts, which constitute a common food of the peasantry. The forests supply plenty of wood for fuel and timber for building. The climate is generally chill and moist, but more temperate on the sea coast than in the interior. The Galicians (Gallegos, in Spanish) are a hardy, industrious, and docile people, but not cleanly either in their persons or dwellings.

In their habits they resemble their neighbours the Portuguese, rather than the rest of the Spaniards. They speak a dialect which has considerable resemblance to the Portuguese language. Many of them visit Portugal, and numbers may be seen in the streets of Lisbon and Porto employed as porters and water-carriers; and they have an established reputation for honesty. The principal manufacture of the country is linen, which is made in great quantity and of very good quality, and chiefly in private families; besides supplying their domestic wants, it is exported to other provinces.

The population of Galicia is almost entirely agricultural; landed property is much subdivided, and the great majority of the people do not live in towns and villages, as in most other provinces of Spain, but in detached dwellings on their lands and fields. The parishes contain each a certain number of lugares, and each lugar consists of a certain number of houses, not at a great distance from each other. There are but few towns or large villages: the principal towns, which are at the same time heads of districts, are as follows:—1. La Coruña [CORUNA], which is the residence of the captain-general: 2. St. Iago de Compostela [COMPOSTELA], where is the high court of justice for the whole province; 3. Betanzos, with 5000 inhabitants, on the river of the same name, in a fine country and mild climate, has a few manufactories, and carries on some trade in wine and pickled sardines, which are fished all along this coast; 4. Mondoñedo, with 6000 inhabitants, and a bishop's see, has a royal college, and a seminary for clerical students; 5. Lugo the antient Lucus Augusti, a Roman colony, has now 7200 inhabitants, is a bishop's see, has some fine old buildings, and some remains of Roman walls. It lies on the left bank of the Miño, nearly in the centre of the province, and on the high road from Coruña to Madrid: its climate is among the coldest in Galicia. 6. Orense, with 4000 inhabitants, a bishop's see, a fine bridge on the Miño, and hot mineral waters, is situated in a district abounding with good wine. 7. Tuy, a frontier town on the side of Portugal, situated on the right bank of the Miño, has 6000 inhabitants, is a bishop's see, has a fine cathedral, and is in a fertile district. The other principal towns are: 8. Vigo, on the fine Bay of the same name, forming one of the largest and safest natural harbours in Spain. Vigo carries on a considerable trade with America, exporting wine, sardines, linen cloth and stockings, and other articles of native industry. It has 5700 inhabitants, and is defended by two castles. 9. FERROL.

Upon the whole Galicia is one of the most important provinces of Spain, and not one of the least industrious; its large population, being chiefly of a rural character, is much under the influence of the parochial clergy.

The antient name of the country was Gallæcia: it was partly conquered by Decimus Junius Brutus (Livy's *Epitome*, 56) and afterwards entirely subjugated by Augustus, when it became a part of the Tarraconensis province. It was afterwards conquered by the Visigoths; at a later period the Moors invaded it, but it was soon reconquered by the Christian princes of Asturias, to whose kingdom it was annexed. (Miñano, *Diccionario Geografico de España.*)

GALICTIS. [GRISON.]

GALILEE. [PALESTINE.]

GALILEI, VINCENTIO, a noble Florentine, and father of the illustrious Galileo Galilei, was born in the early half of the sixteenth century, and studied music under Zarlino, though he did not hesitate to attack the opinions of his master, in a *Discorso intorno all' Opere del Zarlino*, and afterwards in his great work, the *Dialogo della Musica antica e moderna*, a folio volume, printed at Florence in 1581. This work, which displays vast erudition and laborious research, has afforded much assistance to the musical historians of later days: but the author occasionally betrays a hardiness in assertion, of which his more philosophic son was never guilty. He was an exquisite performer on the lute, an instrument, he tells us, that was better manufactured in England than in any other part of Europe. He was a rigid Aristoxenian, and his prejudices in favour of the antients were strong; nevertheless his *Dialogo* is well worth the notice of the curious inquirer into musical history.

GALILE'I, GALILE'O, who is most commonly known under the latter, which was his Christian name, was the son of Vincentio Galilei. He was born at Pisa, in Tuscany, on the 15th of February, 1564.

Having acquired, during his boyhood, and under adverse circumstances, the rudiments of classical and polite literature, he was placed by his father at the University of Pisa in his 19th year. Galilei was designed for the medical profession, but that genius for experiment and demonstration, of which he exhibited the symptoms in his earlier youth, having found a more ample scope in the university under the kind auspices of Guido Ubaldi, with whom he had become acquainted through his first essay on the Hydrostatic Balance, he determined to renounce the study of medicine and pursue geometry and experimental philosophy. This resolution, to which his father reluctantly agreed, was highly approved by those who had witnessed his extraordinary talents, and was perseveringly followed up by him through the rest of his life.

His first important discovery was the isochronism of the vibrations of a simple pendulum sustained by a fixed point. This property is not rigorously true where the arcs of oscillation are considerable and unequal, nor does Galilei ever seem to have adopted any contrivance similar to a fly-wheel, by which these arcs may be rendered equal. His knowledge too of the force of gravity, of the decomposition of forces, and of atmospheric resistance, was too imperfect to conduct him to any valuable improvement of the instrument, and hence the fair claims of his successor, Huyghens, so well supported by his treatise 'De Horologio Oscillatorio,' cannot with any justice be transferred to Galilei, whose merits are sufficiently abundant and conspicuous to need no borrowed attributes. This equality or near equality of the time of vibrations Galilei recognised by counting the corresponding number of his own pulsations, and having thus perceived that the pendulum oscillated more slowly or rapidly according to its less or greater length, he immediately applied it to the medical purpose of discovering the state of the pulse; and the practice was adopted by many Italian physicians for a considerable time.

Through the good offices of Ubaldi, who admired his talents and foresaw their future development, Galilei became introduced to the grand-duke Ferdinand I. de' Medici, who appointed him mathematical lecturer at Pisa (1589), though at an inconsiderable salary. Here he commenced a series of experiments on motion, which however were not published until long after, and then only a scanty portion. This circumstance is probably not much to be regretted, since his inferences on the relation of velocity to space were incorrect at first; but he had learned enough from his experimental course to perceive that most of the scholastic assumed laws of motion were untenable.

The mind of Galilei becoming thus unfettered from the chain of authority, he resolved to examine the rival systems of astronomy—the Ptolemaic, with its cumbrous machinery of cycles and epicycles, eccentrics and primum mobile, and the Copernican, which, from its simplicity and gradually-discovered accordance with phænomena, was silently gaining proselytes amongst the ablest observers and mathematicians. He soon discovered and proved the futile nature of the objections then usually made against it, which were founded on a complete ignorance of the laws of mechanics, or on some misapplied quotations from Aristotle, the Bible, and the Fathers: and having also observed, that many who had at first believed the former system, had changed in favour of the latter, while none of those attached to the latter changed to the Ptolemaic hypothesis—that the former required almost daily some new emendation, some additional crystalline sphere, to accommodate itself to the varying aspects of the celestial phænomena—that the appearance and disappearance of new stars contradicted the pretended incorruptibility of the heavenly bodies, together with other reflections which he has collected in his dialogues,—he became a convert to the Copernican system, and, in his old age, its most conspicuous martyr. So strong however were the religious prejudices on the subject of the quiescence of the earth, that Galilei thought it prudent to continue to lecture on the hypothesis of Ptolemy, until time should afford a favourable opportunity to destroy the visionary fabric by incontestable facts.

One of the false doctrines which he first combated was that bodies of unequal weights would fall through the same altitude in unequal times: thus, if one body were ten times as heavy as another, it should fall through 100 yards while the lighter had only fallen through ten. But though the experiment was performed from the leaning tower at Pisa, and both bodies reached the ground at almost the same instant (the small difference, as Galilei rightly observed,

being attributable to the unequal resistances of the air), the witnesses of this experiment were not convinced, so inveterately were they prejudiced in favour of the doctrines in which they had been taught to place implicit belief.

Instead of making converts by his experiments, Galilei discovered that he had made many secret and some open enemies; he therefore left Pisa and removed to the university of Padua (1592), where he was appointed to a professor's chair for the limited period of six years. Here he invented an imperfect species of thermometer, depending on the expansion of the air which remained after a portion was expelled by heat from a narrow glass tube, which was then inverted and immersed in water. His correspondence with Kepler commenced about the same period, and continued with the greatest mutual friendship and regard until his death. A treatise on the Sphere, after the Ptolemaic system, which is attributed to Galilei, appeared about the same time. (Afterwards published at Rome, 1655.)

On his re-appointment to the professorship at Padua his salary was doubled, his fame increased, and his lectures were crowded: but these flattering events were over-balanced by a disagreeable intermittent disease to which he then first became subject, and which pursued him for the remainder of his life. A new star, almost as brilliant as that which directed Tycho Brahe's mind to the study of astronomy, having appeared in 1604, in the constellation of Ophiuchus, he made it the subject of his lectures, which it may be presumed were less explanatory of its cause, than intended as an attack upon the Ptolemaic system. The conjecture now most generally adopted relative to these remarkable phænomena is, that luminosity is not essential to the central body or sun of a planetary system, consequently the star may be quite opaque or partially luminous, and therefore would be either absolutely invisible or only seen when the luminous portion was in the line joining the earth and star: this explanation is sufficient for those which appear and disappear with regularity; in other cases this transitory phænomenon may merely indicate an epoch of change in the cosmogony of the peculiar system of the star.

Astronomy did not however engross all the attention of Galilei. He read and admired Gilbert's work, 'On the Nature of Bodies,' and adopted his views on the subject of terrestrial gravity, and constructed magnets after his example; about the same time he attacked with some bitterness one Capra, who ascribed to himself the invention of a species of compass which Galilei had made; and he wrote also on practical methods for the measurement of heights and distances. Shortly afterwards he states in a letter, that 'he intended hereafter to write three books on the system of the universe; three books on local motion; three books of mechanics; also on sound, speech, light, the tides, continuous quantity, animal motion, and castrametation; many of which, it is supposed, were destroyed by his relatives after his death, at the instance of the family confessor.

The year 1609 was signalized by the construction of the Galilæan telescope, which consisted of a plano-convex object-glass, and a plano-concave eye-glass, and thus he laid the foundation of the brilliant discoveries in the solar system, which have rendered that science the most perfect of which the objects are the most remote. It is true that Jansen, a Dutch optician, and some others previous to him, had constructed microscopes, and perhaps imperfect telescopes, but they cannot claim the invention of the astronomical telescope, their articles having been more intended for toys and puerile amusement than any valuable practical purpose; and as they had no notion of applying them to the heavenly bodies, it is obvious that their random constructions would be totally inapplicable to such a purpose. However the long-mooted question of the invention of this noble instrument of science may be decided, its application by Galilei to astronomy, for the first time, is indisputable. His first telescope was presented to the Doge of Venice, by whom the professorship at Padua was confirmed to him for life, with the greatest salary which had ever been there given to the mathematical professor, viz., about 1000 florins.

Galilei, impatient to obtain ocular evidence of what he called the 'structure of the universe,' soon provided himself with a second instrument, and on directing it towards the moon, this luminary became immediately stripped of the character of geometrical perfection, absurdly attributed to all the celestial bodies by the schoolmen, according to whom they were all perfectly round, self-luminous, and uncorrupted by any terrestrial tarnish.

The more obscure parts of the lunar surface, which they imagined had arisen from some earthly taint consequent on the proximity of the moon, being now rendered distinctly visible, taught Galilei that the surface of the moon was irregular and uneven, having mountains and valleys of much greater extent, in proportion, than those on our globe; the faint light on the darkened portion of the moon's surface he recognised to be the reflection of the sun's rays from the earth; the luminous isolated points near her inner border, and the jagged outline of that border, showed the great inequalities on her surface, since the mountain-tops would be illuminated by the sun, while the sides and base would lie in obscurity, in consequence of the convexity of the surface. In pursuing these observations, he found that the moon turns towards the earth the same face constantly, so that nearly a hemisphere of her surface can never be visible to us. From this remarkable fact he does not appear to have drawn the inevitable consequence, that the time of her rotation round her own axis, and the time of a revolution round the earth, must be exactly equal. Lagrange afterwards suggested that this effect was primitively caused by the determination of the lunar figure, in which the heavier part being originally accumulated towards the attracting primary, the moon, in its revolution, would always have a tendency to fall towards the heavier side so determined. Galilei subsequently observed the librations of the moon, by which small portions of her more distant hemisphere are alternately brought in view; but he was not in a situation to give a satisfactory explanation of the cause, from the imperfection of theoretical astronomy. The idea which was suggested from the appearance of oceans and continents, mountains and valleys, on the moon, that she might be habitable, overwhelmed the schoolmen with horror, and struck the religious with alarm.

On examining the nebulæ, and particularly the Milky Way, with his glass, he perceived that they were composed of myriads of stars, or, in the language of Milton, 'powdered with stars.' It may be remarked in passing, that Milton visited Galilei, and entertained the highest opinion of his philosophy, to which he makes several beautiful allusions in his 'Paradise Lost.'

The planet Jupiter furnished matter for still greater wonder. Galilei perceived three very small stars eastward of the planet, and close to its disc; two of them, on a subsequent observation, had distinctly changed position to the westward: he soon perceived that they were satellites; and shortly afterwards he discovered the fourth. The strength which this discovery gave to the Copernican system, from the analogy with our moon, however gratifying to Galilei in a speculative point of view, did not prevent his ever-active mind from perceiving its great practical importance in the question of determining longitudes at sea; but it was reserved for a future age to bring this and other methods to a degree of perfection then impracticable. The theory of astronomy and the construction of chronometers were, at that time, in a most imperfect state; and though Galilei offered his services to Spain, then a great maritime power, it is doubtful whether he would not have had cause for regret if the wished-for arrangement had taken place. The manner in which he was assailed after this discovery must have caused him amusement rather than chagrin: some would not look through his glass to be convinced; one Horky asserted that he had used the telescope, and that he saw nothing of the kind; one thought it odd that nature should give satellites to Jupiter for no purpose but to immortalize the Medici family (for Galilei had denominated them Medicean stars, in honour of his patron). Some time after, his opponents found out five satellites for Jupiter instead of four: while one had the impudence to say that he actually saw nine satellites. (1610.)

On examining Saturn with the telescope he perceived his ring, or rather rings (as Sir W. Herschel has since shown), but viewing it in perspective, he took the lateral portions for two small stars, which induced him to announce in transposed letters the following sentence —

'Altissimum Planetam tergeminum observavi.'
(The most distant planet I have observed to be threefold.)

Huyghens was the first who corrected this error; though it is remarkable that the occasional disappearance of the supposed lateral planets, which arose from the relative

change of the position of the ring, which so much astonished Galilei, had not suggested to him the correct nature of the phænomenon: we must however remember the great imperfections of the first-constructed telescopes.

His next discovery he also concealed in the same enigmatical manner; the transposed letters signify, in their proper order—

'Cynthiæ figuras æmulatur mater amorum;'
(Venus rivals the moon's phases;)

alluding to the crescent form of this planet when in or near conjunction. His discovery of spots on the sun's disc, which were evidently attached to that luminary, was a severe blow to the imaginary perfection of the schoolmen.

The Jesuits had always entertained a cordial hatred for Galilei, as he had joined the party by whom they had been expelled from Padua; the progress of his discoveries was therefore reported to the Inquisition at Rome, as dangerous to religion, and he was openly denounced from the pulpit by Caccini, a friar. In his own justification he wrote letters, one to his pupil Castelli, and another to the archduchess Christina, in which he repudiates any attack upon religion, and states that the object of the Scriptures was to teach men the way of salvation, and not to instruct them in astronomy, for the acquiring of which they were endowed with sufficient natural faculties. Nevertheless the Inquisition was implacable, and ordered Caccini to draw up depositions against Galilei; but his appearance in person at Rome in 1615, and his able defence of his conduct, for a moment silenced his persecutors.

In March, 1616, the pope (Paul V.) granted Galilei an audience, and assured him of his personal safety, but positively required him not to teach the Copernican doctrine of the motion of the earth: Galilei complied, and left Rome in disgust. He had soon occasion to turn his attention again to Astronomy, for in 1618 there appeared no less than three comets, on which occurrence Galilei advised his friends not to conceive too hastily that comets are like planets, moving through the immensity of space, but that they may be atmospheric: his reasons for this, though ingenious, are fallacious, as are those which he afterwards gave for t causes which produce tides, which he attributes to the unequal velocities of different parts of the sea by reason of the combination of the rotatory and progressive motions of the earth, which at some points conspire together and at others are opposed. Wallis afterwards seems to have adopted the same opinion, which could never have been entertained had either of them reflected on the complete independence of the rotatory and progressive motions of bodies. The motion of the whole solar system too would, on their supposition, have affected the tides; but Dynamics had as yet no existence, and Galilei often frankly confesses that he is more a philosopher than a mathematician. He afterwards went to Rome, and was received with great kindness by the next pope (Urban VIII.): his enemies were silenced for awhile, and he was sent home to Tuscany loaded with favours and presents: and though his patron, Cosmo II. de' Medici, was dead, his successor, Ferdinand II., showed him strong marks of esteem and attachment.

In 1630 he finished, and in 1632 completed his celebrated work, 'Dialogue on the Ptolemaic and Copernican Systems,' which he dedicated to Ferdinand II. By giving the work this form, his object seems to have been to evade his promise not to teach the Copernican doctrines. Three fictitious persons conduct the dialogue: Salviati, a Copernican; Sagredo, a banterer on the same side; and Simplicio, a Ptolemaist, who gets much the worst both by jokes and argument. The pope, who had been personally friendly with Galilei, fancied that he was the person held up to ridicule in the last character, as some arguments which he had used had been put into Simplicio's mouth; he was therefore mortally offended, and the Inquisition resolved not to allow the attempted evasion of Galilei's solemn promise. Galilei was accordingly summoned to Rome, though he was 70 years of age and overwhelmed with infirmities; he had however all the protection and comforts which the Grand Duke could confer on him, being kept at the Tuscan ambassador's house, and this spirited man (Nicolini) even wished to maintain him at his own expense when he perceived a penurious disposition in Ferdinand's minister.

After some months' residence in Rome he was again summoned before the Inquisition, and on the 20th of June appeared before the assembled inquisitors in the Convent of Minerva. The whole of his sentence is too long to be transcribed here, but a portion of it is too curious to be omitted.

'By the desire of his Holiness and of the most eminent Lords Cardinals of this supreme and universal Inquisition, the two propositions, of the stability of the sun and motion of the earth, were *qualified* by the Theological Qualifiers as follows:—

1st. The proposition that the sun is the centre of the world and immoveable from its place, is absurd, philosophically false, and formally *heretical*; because it is expressly contrary to Holy Scripture.

2ndly. The proposition that the earth is not the centre of the world, nor immoveable, but that it moves, and also with a diurnal motion, is absurd, philosophically false, and theologically considered at least *erroneous* in faith.'

After a long and declamatory exposé, from one passage in which it has been suspected that Galilei was put to the torture, it concludes thus—

'We decree that the book of the Dialogues of Galileo Galilei be prohibited by edict; we condemn you to the prison of this office during pleasure; we order you, for the next three weeks to recite once a week the seven penitential psalms, &c. &c.'

To obtain so mild a sentence Galilei was obliged to abjure, on the Gospels, his belief in the Copernican doctrine. We quote a part of his abjuration:

With a sincere heart and unfeigned faith I abjure, curse, and detest the said errors and heresies (viz. that the earth moves, &c.); I swear that I will never in future say or assert anything, verbally or in writing, which may give rise to a similar suspicion against me. . . .

'I Galileo Galilei have abjured as above with my own hand.'

Rising from his knees after this solemnity, he whispered to a friend, 'E pur se muove:' 'It moves, for all that.'

This sentence and abjuration having been generally promulgated, the disciples of Galilei found it necessary to act with prudence, but their esteem for their master was not diminished by this compulsory abjuration

Afflictions followed quickly the old age of Galilei. In April, 1634, he lost a beloved daughter who was his only stay. He was allowed to return to Arce breathed her last, but he was still kept in strict confinement. After two years spent in this unhappy condition his confinement became more rigorous through some new suspicions entertained by the pope, so that after having been allowed to remove to Florence for the benefit of his declining health he was ordered to return to Arcetri. In 1636 he became totally blind, about which time he finished his 'Dialogues on Motion,' which were remarkable enough for the time for any other man, though not perhaps commensurate with the high ideas associated with the name of Galilei; and though he believed this work could not annoy the holy office, yet the terror was so great and universal that he could not get it published until some years after, when it was undertaken at Amsterdam.

Amongst the most celebrated pupils of Galilei are Viviani and Torricelli, the former of whom in particular bore a strong attachment for his master. While Torricelli was arranging a continuation for the 'Dialogues on Motion,' Galilei was suddenly taken ill with a palpitation of the heart, and, having lingered two months, he died on the 8th January, 1642.

He appears to have been of a sprightly temperament, easily crossed and easily reconciled; his kindness to his relatives, which distinguished him from his childhood to old age, and which went frequently to such an extent as to embarrass himself, forms a noble trait in his domestic character; he was somewhat attached to the bottle and was considered a good judge of wine; he contrived to have his son Vincentio legitimized, but afterwards had the misfortune to find his hopes in this lad rather disappointed. Galilei was also acknowledged to have an excellent taste for music, painting, and poetry, and the style of his 'Dialogues' is still much praised by his countrymen.

His works have been collected in 13 vols. 8vo., Milan, 1811; there have been also several other collections of the same, and they have been published in separate tracts.

Viviani, his disciple, wrote his life and left a legacy to raise a monument to his memory. Newton was born one year after Galilei's death.

One of the best-written biographies of Galilei that has yet appeared is by Mr. Drinkwater.

GALINUS. The reference to this word is a typographical error. It should have been GALIACEÆ, which see.

GALIPE'A, a genus of Rutaceous shrubby or arborescent plants, inhabiting the warmer parts of South America. Their leaves are often simple, occasionally 3-4-5-leafleted, not divided at the edge, covered with pellucid or glandular dots. The flowers are small, white or pink, often fragrant, in axillary, extra-axillary or terminal, racemes, corymbs, or panicles. The most remarkable species is the Galipea or Bonplandia trifoliata, which has also been called Cusparia febrifuga, and Galipea Cusparia, a plant yielding Angostura bark, a medicine employed as a febrifuge and in dysentery. It is found in the neighbourhood of Angostura on the Spanish Main.

GALIPEA. (Materia Medica.) The genuine Angostura or cusparia bark is obtained from a species of this genus, but whether from the G. cusparia, as stated by Humboldt, or by a distinct species, G. officinalis, as asserted by Dr. Hancock, is not determined. Angostura bark is obtained both from the stem and branches; the specimens from the stem are flat, from 2 to 3 lines thick, while those from the branches are often quilled, and from ½ to 1 line thick. The pieces are sometimes from 6 to 15 inches, but more frequently only from 2 to 6 inches long, and from ½ to 2 inches broad. Some specimens have the surface covered with a thick, fungus-like, whitish-yellow or clay-coloured crust, which may be more or less easily scraped off, and beneath which is a yellowish-red smooth bark, often exhibiting small cracks. Other specimens have this covering much thinner and closely adhering to the bark. The internal surface is generally smooth, of a tawny or reddish-yellow colour.

The bark is easily broken, and the recent fracture is of a brownish-red colour, smooth, with a resiny shining surface. The shining appearance is best seen when a transverse section is made with a sharp knife. The smell is disagreeable: the taste pleasantly bitter, warm, aromatic, and causing a flow of saliva. The powder has the colour of rhubarb. The infusion is of an orange-yellow colour; the decoction a clear light brown.

Brandes thought that he had discovered an alkaloid, which he proposed to call Angosturin, but it has not been detected by subsequent chemists. This bark contains neither gallic acid nor tannin. According to the analysis of Fischer it consists of—

Volatile oil (of an acrid nature)	0·3
Bitter hard resin	1·7
Balsamic soft resin	1·9
Elastic resin	0·2
Bitter matter (Angosturin bitter)	3·7
Gum	5·7
Woody fibre	89·1
	102·6

So minute an account of this substance would not be necessary, were not the true Angostura bark liable to be confounded with the false, which possesses such poisonous properties that very fatal consequences have resulted from the substitution of the one for the other. It is probable that the false is the bark of some species of South American strychnos, as it contains strychnia as well as brucia [BRUCIA], two most potent alkaloids. The idea that this spurious bark is obtained from the Brucea ferruginea is entirely unfounded, as that tree grows in Abyssinia, and the false Angostura bark comes mixed with the genuine, and not as an isolated or distinct commercial article.

False Angostura bark was first observed in 1804 by Dr. Rambuch, of Hamburg, by poisonous effects following the use of a decoction of the bark; and similar consequences having been observed at Vienna, the Austrian government ordered all the Angostura bark in the empire, genuine as well as false, to be burnt, and interdicted its future importation. The Russian and Würtemberg authorities made known the danger, and published the marks of distinction, which are sufficiently characterized, and to prevent accidents, may be here enumerated.

Genuine.	*Spurious.*
Pieces 2 to 4 inches long; from ½ to 2 inches broad; from ¼ to ¾ of a line thick.	Pieces of greater breadth than length; thickness never less than a line, often two lines.
Epidermis having on it a number of different lichens (often as many as 40 species), and a yellow membranous crust.	Epidermis generally clear (but sometimes undergoing a peculiar transformation), and seldom having any, or not more than two lichens (Opegrapha Pelletieri, and Pyrenula nitida).
The incrustation spongy and insipid, and not changing colour by the action of nitric acid.	The crust has the general properties of the bark, and assumes a deep green by the action of nitric acid. It contains a resinous colouring principle, Strychnochromin.
Crust easily removed by the nail.	Crust not easily removed.
Inner surface yellow, and separable into layers.	Inner surface brown, or even black, not separable into layers.
Texture not close, weight light, easily broken, fracture even, shining, and resinous. Cuts transversely without difficulty.	Texture compact, heavy, not easily broken, fracture even, but not shining or resinous, exhibiting two layers. Very difficult to cut.
Placed in water it soon imbibes it, and becomes soft.	Scarcely softens in water.
Smell strong and disagreeable.	No smell.
Taste an aromatic and enduring bitter, but not at all disgustingly bitter.	Taste in the highest degree disgustingly bitter: very durable, and not at all aromatic or astringent.

Re-agents produce the following effects on a cold infusion of each:—

Colour of infusion of genuine, orange yellow. *Colour of infusion of spurious, light yellow.*

Cold Infusion.	Tincture of Galls.	Bi-chloride of mercury.	Sulphuric Acid.	Proto-sulphate of iron.	Perchloride of iron.	Carbonate of potass.
Genuine Angostura.	Yellowish precipitate.	Copious precipitate.	Very turbid.	Whitish-grey precipitate.	Yellowish brown precipitate.	Dark red colouring, with slight precipitate.
Spurious Angostura.	White precipitate.	Renders turbid only.	No action.	Green colour, slightly turbid.	Yellowish green colour.	Greenish colouring, with dirty yellow precipitate

Spurious Angostura bark, in the dose of eight grains, killed a dog in two hours; ten grains killed a young dog in a few minutes. A very small glassful of an infusion endangered the life of an adult, while a dose of the decoction destroyed a child with acute suffering. Æther and laudanum seem to act as antidotes. The dread of similar casualties from the employment of the spurious instead of the genuine Angostura bark, has prevented the use of the latter to that

extent which it merits. In the treatment of the bilious diarrhœa, frequent in damp autumns in this country, after proper evacuants, it is of the most decided utility. In common English cholera likewise, and slighter cases of Asiatic cholera, it is the most beneficial agent which can be resorted to. It is best given in the form of infusion, and may either be administered alone, or with the addition of dilute nitric acid and tincture of opium, which last may be discontinued after a few doses. (Abercrombie, *On Diseases of the Stomach, &c.*)

GALL, ST., THE CANTON OF, one of the cantons of the Swiss Confederation, situated at the north-east extremity of Switzerland, is bounded on the north by the canton of Thurgau and the lake of Constance; east by the Austrian province of the Vorarlberg; south by the cantons of Grisons and Glarus, and west by those of Schwyz and Zürich. Its area is reckoned at 780 square miles, and its population, which has been rapidly increasing for the last twenty years, amounted in 1831 to 165,740 inhabitants, of whom 62,500 were Protestants and the remainder were Catholics. St. Gall is a new canton, which was formed at the beginning of the present century by the union of the territories of the Abbot of St. Gall with the free town of St. Gall, and several districts formerly subject to the old cantons, namely, the Rheinthal, Sargans, Werdenberg, Utznach, Gaster, and Sax, and the town of Rapperschwyl. By the agglomeration of so many various districts which happened to be situated all round the old canton of Appenzell, that canton is now enclosed on every side by the territory of St. Gall. (APPENZELL.) The spoken language of St. Gall is a dialect of the German, resembling the Swabian.

The canton of St. Gall is in great part a mountainous country, being intersected by various offsets of the Alps, the highest of which are continuations of the great chain which bounds on the north the valley of the Upper Rhine in the Grisons country, and which on entering the territory of St. Gall at the summit called Scheibe (9000 feet) divides into three branches, one running north along the frontiers of Glarus as far as the south bank of the lake of Wallenstadt, another eastwards between St. Gall and the Grisons, forming the summit called Galanda (8800 feet high) and the third extending north-east into the canton of St. Gall, between the rivers Tamina and Seez. North of the lake of Wallenstadt is another chain running in a north-west direction, which divides the basin of the Linth from that of the Thur, and contains several summits between 6000 and 7000 feet high. North of the Thur and between it and the lake of Constance is another extensive group of mountains, known by the name of Alpstein, which cover nearly the whole of Appenzell, and extend also into the adjacent districts of St. Gall. The general slope of the surface is towards the north and north-west, the streams running in those directions. The principal rivers are: 1. the Rhine, which coming from the Grisons touches the canton of St. Gall near Pfäffers, and flowing northwards forms its eastern boundary for a length of about fifty miles, dividing it first from the Grisons, and afterwards from the Vorarlberg, until it enters the lake of Constance below Rheineck. Its principal affluent in the canton of St. Gall is the Tamina, a rapid Alpine stream which rises in the Scheibe, crosses the south part of the canton, passes by Pfäffers, and enters the Rhine below Ragaz. 2. The Seez, which rises also in the south part of the canton, runs first north-east and then north-west, and enters the lake of Wallenstadt. 3. The Thur, which rises in the central part of the canton near Wildhaus, Zuingli's birth-place, runs northwards through part of the fine district of Toggenburg, passes by Lichtensteg, receives the Necker on its right bank, and after a course of about forty miles enters the canton of Thurgau near Bischofszell. 4. The Sitter, which coming from the canton of Appenzell, passes near the town of St. Gall and enters Thurgau, where it joins the Thur. 5. The Goldach, which rises also in Appenzell, and runs into the lake of Constance. The north and north-west districts of the canton towards the borders of Thurgau are mostly level, as well as the banks of the Linth, between the lakes of Wallenstadt and Zürich, where an extensive marsh has been drained by means of the canal of the Linth.

The agricultural produce of the canton consists chiefly of wine, fruits in great abundance, especially apples and cherries, some corn, Indian corn, potatoes, and pastures. There are considerable forests in the southern part of the canton, and much wood is exported. The domestic animals are oxen, sheep, goats, pigs, and horses; the rivers and lakes abound with fish and water-fowl. There are rich iron-mines at Gunzenberg; and coals and turf are found in several districts. Manufactures constitute an important branch of industry. Ever since the thirteenth century the town of St. Gall was known for its linen manufactories, which now have been replaced by those of cotton goods and especially muslins. In 1828, 124,000 pieces of muslins and other cotton goods were manufactured in the canton. The women are also employed in embroidery, for learning which there is a gratuitous school for poor girls. The tanneries have fallen off of late years, the people now preferring to export raw hides. About 3000 bullocks' hides and 2000 goats' skins are exported annually. The town of St. Gall is a place of great trade, especially with Germany and Italy, and contains some wealthy merchants, manufacturers, and bankers or bill-brokers.

The canton is divided into fifteen districts, namely: St. Gall, Tablat, Rorschach on the banks of the lake of Constance, Unter Rheinthal, Ober Rheinthal, Werdenberg, Sargans, Gaster, See Bezirk on the banks of the lake of Zürich, Ober Toggenburg, Unter Toggenburg, Alt Toggenburg, Neu Toggenburg, Wyl, Gossau. The finest districts are the Rheinthal, Rorschach, St. Gall, Wyl, the greater part of the Toggenburg, and the See Bezirk; the remaining or southern districts are mountainous.

St. Gall, the capital of the canton, once a free imperial city, and afterwards an ally of the old Swiss cantons, is situated in a pleasant valley, is well built, well supplied with water, and contains above 400 houses within the walls, and 8900 inhabitants, of whom 1230 are Catholics. The principal buildings are, the old Abbey Church, one of the finest in Switzerland, with handsome paintings: the former convent, now a gymnasium; the Casino or assembly-room, the town-house, several hospitals and asylums, and the public granaries. The old Abbey library has above 1000 MSS., many of them valuable; several of the classics which were considered as lost, were discovered in the middle ages in this library by Poggio Bracciolini and other philologists. St. Gall is one of the most commercial towns of Switzerland; but its inhabitants are likewise fond of the sciences and literature, as appears from the existence of numerous societies, private libraries, collections of natural history, and other similar establishments within the town. The environs are embellished with numerous country-houses and promenades. St. Gall is forty miles east of Zürich, and forty-five miles north of Coire in the Grisons. Rappertswyl is prettily situated on a peninsula projecting into the lake of Zürich, with a bridge 4500 feet long, which crosses over to the south bank of the lake; it has some manufactories and about 1500 inhabitants. Altstätten in the upper Rheinthal, in the midst of a fertile country, is a place of some trade, with about 6000 inhabitants, including its commercial territory. Rheinek in the lower Rheinthal, on the left bank of the Rhine, which separates it from the Austrian territory has about 1400 inhabitants: the red wine made in the neighbourhood is among the best in Switzerland.

The government of St. Gall is a democracy. The members of the Great Council or Legislature are chosen in their respective districts by all the citizens above twenty-one years of age, except those who are supported by the public charities, bankrupts, and those whose immoral conduct is attested by legal proof. The members are elected for two years. The Great Council appoints from among its body the members of the Little Council or Executive for four years. It also appoints those of the Criminal Court and of the Court of Appeal. The citizens of each district appoint every year their own amman or prefect, and other local authorities. All the laws emanating from the Great Council are subject to the sanction of the electors of the various communes, if they choose to exercise their right within forty-five days after the passing of the law: that period being expired without any objection made by the majority of the communes, the law becomes in force. All absent electors are considered as voting in favour of the law. The constitution of St. Gall is one of the most democratic among the representative cantons of Switzerland: it approaches nearly to that of the landsgemeinde or pure democracies of the little cantons. This constitution dates from 1831, when, being laid before the communal assemblies for their sanction, the number of citizens having the right of voting being 32,980, it was negatived by 11,097, and approved of by 9,253, to which latter number was added that of 12,630, who were absent, and

who were considered, according to a clause in the project of the constitution itself, among the ayes.

The revenues of the state derived from the income-tax, licenses for shops, public-houses, and sporting, stamp-duties, tolls, monopoly of salt, post-office, and national domains, amounted in 1835 to 305,597 florins, and the expenditure of the same year was 274,054 florins. Each of the two religious communions in the canton administer their own affairs. The Catholics have a Board of Administration; the property of their church is 1,627,776 florins, and they have four convents of monks and ten nunneries. They were formerly under the diocese of the bishop of Coire and St. Gall; but in 1833, on the death of the last bishop, the Catholics of St. Gall refused to acknowledge his successor, appointed by the pope; the Grisons likewise demanded the separation of their diocese from that of St. Gall; and after much discussion, the pope, in 1836, decreed the dissolution of the double bishoprick, and appointed an apostolic vicar to superintend the ecclesiastical affairs of St. Gall and Appenzell. The abbot of St. Gall has long since lost all his domains and revenues, and the convent has been suppressed. A pension was offered to the last abbot, Pancratius, in 1814, which he refused, and claimed the restoration of his former rights. Having endeavoured in vain to interest the Allied powers in his favour, he retired to the convent of Müri, in the canton of Lucerne. (Lereshe, *Dictionnaire Géographique Statistique de la Suisse*; Walsh, *Voyage en Suisse*; Franscini: Dandolo.)

GALL, DR. FRANZ JOSEPH, the founder of the system of phrenology, was born at Tiefenbrunn, in Suabia, on the 9th of March, 1757. He seems at a very early age to have evinced habits of accurate observation, for it is said that, when a boy at school, he often amused himself with remarking the differences of character and talent among those educated alike, among his brothers and sisters, and his playmates and schoolfellows. He saw, too, that these characters seldom changed—that education rarely altered the good or bad temper of a child, or gave the talent which he exhibited in one subject a direction towards another. He observed that the boys who were his most formidable competitors were all distinguishable by a peculiar expression of countenance, the result of unusual protrusion of the eye-ball, which seemed to him a certain sign of talent. On his removal to another school he still found himself invariably beaten by his 'bull-eyed' companions, as he called them, and making the same observations as before, he found all his playmates still distinguished for some peculiar talent or temper. He next went to the university of Vienna to pursue his studies for the medical profession, and at once began to search for prominent eyes among his fellow-students; all that he met with were, as he found, well known for their attainments in classics, or languages generally, or for powers of recitation; in short, for talent in language; and hence the sign of a prominent eye, which he had first thought indicated talent generally, he became convinced marked a facility for acquiring a knowledge in words, which was the principal study in the schools of his boyhood. This coincidence of a peculiar talent with an external physiognomic sign, led him to suspect that there might be found some other mark for each talent, and remembering that at school there were a number of boys who had a singular facility in finding birds' nests, and recollecting where they had been placed, while others, and especially himself, would forget the spot in a day or two, he began to search among his fellow-students for all who indicated a similar knowledge and memory of places, that he might see in what feature that would be indicated, and he soon thought he found them all marked by a peculiar form of the eye-brow. He now felt convinced that by accurate observation of the shape of the head in different persons, he should find a mark for every kind of talent, and he lost no opportunity of examining the forms of the head in poets, painters, mechanics, musicians, and all distinguished in art or science. He found external signs in each class that separated them from the rest, and he thought he could now clearly discern the character of each by their cranial formation before he inquired into their pursuits or reputation. He had observed that persons remarkable for determination of character had one part of their heads unusually large, and he was therefore led to seek whether there were not signs of the moral affections similar to those which he believed he had discovered to indicate the intellectual powers. After some time he found that these affections also might be ascertained by discerning how far one portion of the head surpassed the others in size. His mind was so completely engrossed with the pursuit of facts to support his belief that he should find a complete key to the human character, that his academic career was marked by no particular success, though his talents might certainly have secured it.

To further his pursuit, he now resorted to the works of the most esteemed metaphysicians of antient and modern days, but here he found little besides unsatisfactory theories, and contradictions of each other, and certainly nothing that at all favoured the view which he had been led to take of the human mind. He therefore gave them up, and resorted again to the observation of nature alone, and he now extended his field. Being on terms of intimacy with Dr. Nord, physician to a lunatic asylum in Vienna, he carefully examined all the insane there, observing the peculiar character of the insanity in each, and the corresponding forms of their heads: he frequented prisons and courts of justice, and made notes of the crimes and appearance of all the prisoners. In short, wherever there was any person made remarkable by good or bad qualities, by ignorance, or by talent, Dr. Gall lost no opportunity of making him a subject of his study. With the same views he was constant in his study of the heads and characters of both wild and domesticated animals. He had always felt sure, that the form of the skull in itself alone could stand in no relation to the intellect or disposition, but it was not till late in his pursuit that he resorted to anatomy to confirm his views. Having obtained his diploma, he made it his care, as far as possible, to ask for leave to examine the brains of all whose characters and heads he had studied during life, and soon found that, as a general rule, the exterior of the skull corresponds in form with the brain contained within it.

At length, after unremitting exertion, and constant study for upwards of twenty years, Dr. Gall delivered his first course of lectures, in 1796, at his house in Vienna. Supported by a vast accumulation of facts, he endeavoured to prove that the brain was the organ on which all external manifestations of the mind depended; that different portions of the brain were devoted to particular intellectual faculties or moral affections; that, *cæteris paribus*, these were developed in a degree proportioned to the size of the part on which they depended; and that, the external surface of the skull corresponding in form with the surface of the brain, the character of each individual was clearly discernible by an examination of his head.

A doctrine so new, and so subversive of all that had been previously taught in psychology, produced no little excitement. To some the number of simple facts, the apparently clear and necessary deductions from them, and the ease with which the new system seemed to lead to the knowledge of a science hitherto so obscure, were sufficient to secure at once their assent, while others said that Gall, beginning with a theory, had found at will facts to support it; that a plurality of powers in the same organ was too absurd to be imagined, and that the doctrine, leading on the one hand to fatalism, on the other to materialism, would, if received, be subversive of all the bonds of society, and opposed to the truths of religion. It was argued with all the ardour with which new doctrines are so generally assailed and defended, but Gall took little part in these disputes, and still continued to lecture and collect more facts.

He gained disciples daily, and in 1800 Dr. Spurzheim became his pupil. In 1804 this gentleman was associated with him in the study of his science, and to this fortunate event phrenology probably owes much of its present clearness and popularity. Spurzheim possessed a mind peculiarly adapted for generalizing facts, of which the science at that time almost entirely consisted, and besides being most ardent and industrious in the pursuit of additional support for the doctrines, he had a suavity of manner and a brilliancy of conversation which prepossessed all in favour both of himself and his science. It is from him indeed that nearly all the knowledge of phrenology at present current in England has been derived; for till his arrival here in 1814, and the publication of his 'Physiognomical System' in 1815, nothing was known of the science except from a small translation of a German treatise in 1807, and some very unfavourable notices of it in periodicals. Since that time too the smaller size and more popular style of his books have made them far more generally known than those of his preceptor, and a large majority of the phrenologists of this country are entirely of the school of Spurzheim.

Soon after their association, Drs. Gall and Spurzheim

commenced a tour through the principal towns in Germany and Switzerland, diffusing their doctrines, and collecting everywhere with the most assiduous industry fresh evidence in their favour. In 1807 they arrived at Paris, which became at once the field of their principal labours, and of the most vehement discussion. Amongst many, it attracted the attention of Napoleon, probably from the extensive practical benefits which it was urged would flow from it. At first he is said to have spoken in no measured terms of the savans of his country, for 'suffering themselves to be taught chemistry by an Englishman (Sir H. Davy), and anatomy by a German.' He afterwards however expressed his disbelief in it, and hence the reason (say the most ardent supporters of the doctrine), why in 1809 the commission appointed by the Institute on the Memoir presented by Gall and Spurzheim, in March 1808, returned a report highly unfavourable to the science and its author. Undaunted however by this severe check to their rising popularity, they continued to study and to teach both by lectures and by voluminous publications till 1813, when a dispute arising, partly as to the degree of credit which each merited for the condition at which the science had then arrived, partly from private motives, they separated. Dr. Gall remained in Paris; Dr. Spurzheim soon after proceeded to England, where he continued for several years lecturing in London and the principal towns of the kingdom, and whence he ultimately proceeded to America.

Dr. Gall continued in Paris till his death, which occurred on the 22nd of August, 1828.—He had suffered for nearly two years previously from enlargement of the heart, which prevented him, except at intervals, from pursuing his lectures, and at length produced a slight attack of paralysis, from which he never recovered. At the post-mortem examination his skull was found to be of at least twice the usual thickness and there was a small tumour in the cerebellum: a fact of some interest, from that being the portion of the brain in which he had placed the organ of amativeness, a propensity which had always been very strongly marked in him.

Whatever may be the merits of the phrenological system, Dr, Gall must always be looked upon as one of the most remarkable men of his age. The leading features of his mind were originality and independence of thought; a habit of close observation, and the most invincible perseverance and industry. Nothing perhaps but a character like this in its founder, and the very popular and fascinating manners of his chief supporter, could have upheld the doctrine against the strong tide of rational opposition and of ridicule with which it was assailed. Whether the system be received or not, it will be granted, that both in the collection of psychological facts which they had formed, and have published, and by the valuable contributions which they have made to the study of the structure of the brain, to which their later labours had been particularly directed, they have conferred very great benefits on medical science. The character of Dr. Gall's writings is singularly vivid and powerful; his descriptions, though slight, are accurate and striking, but his works are too voluminous to be acceptable to the majority of readers, and have therefore, in this country, been almost entirely superseded by those of Dr. Spurzheim, to which however, in substantial value, they are far superior. They comprise 'Philosophisch-Medicinische Untersuchungen über Natur und Kunst im Kranken, und Gesunden Zustande des Menschen,' 8vo. Leipzig, 1800; 'Anatomie et Physiologie du Système Nerveux en général, et du Cerveau en particulier: Mémoire presenté a l'Institut, Mars, 1808;' and under the same title his great work in 4 vols. 4to., and atlas folio, published in Paris, from 1810 to 1819, of which the 1st and half the 2nd volume were written in conjunction with Dr. Spurzheim; and 'Sur l'Origine des qualités morales et des Facultés intellectuelles de l'Homme,' 6 vols. 8vo., Paris, 1825. An English translation of them has lately been published in America by Nahum Capin, and another of the 4to. work is said to be in progress in England.

GALL. [Bile.]

GALL STONES. [Calculus.]

GALLATES. [Gallic Acid.]

GALLEON (*galoion* in French, *galen* in Spanish) was the name given to very large ships, with three or four decks, which the court of Spain used to send at fixed periods to the coasts of Mexico and Peru, to receive on board the gold and silver bullion extracted from the mines, and bring it to Spain. Commodore Anson intercepted, and captured after a short engagement, one of these galleons on its way from Acapulco to Manilla, [Anson.]

GALLERY, in its most extended sense, is used synonymously with corridor. [Corridor.] In England however it is understood to be either a long narrow passage-way, or an open space, generally longer than wide, raised above the floor of a building, and usually supported on columns. Such galleries are met with (among other places) in English churches, in some courts of justice, and in theatres. The long external wooden passage-ways, formed something like a balcony, such as are occasionally seen in old inns, are called galleries. The antients also had their galleries in their basilicæ [Basilica] and in their agoræ. [Forum.] The crypto-porticus was a gallery. The term gallery is also applied to a long room, or a series of rooms containing pictures, as the gallery of the Louvre at Paris.

GALLERY, in military mining, is a subterranean trench, or passage, leading to the place where the powder is deposited for the purpose of producing an explosion.

Of the galleries which appertain to a fortress, the principal one, denominated the magistral gallery, surrounds the place under its covered-way; and the entrances to it are in the counterscarp of the ditch. A second gallery, designated the envelope, is formed under the foot of the glacis, so as either wholly or partially to circumscribe the works; and galleries of communication under the glacis lead to it from the former gallery. Small galleries, sometimes called listeners, are also carried towards the country, from the envelope; in order, as the name implies, that the defenders in them may discover, by the sound, where the enemy's miner is at work.

The galleries of a fortress are at least six feet high and four feet wide, and are lined and vaulted with brick work: they are, or should be, so disposed as to ensure complete drainage: and means must be provided to afford them proper ventilation. At the places where they intersect one another are formed enlargements in which tools may be deposited, and the miners, with their barrows, be enabled to pass each other: verticle grooves are also cut down the sides of a gallery for the reception of the ends of timbers which may serve to barricade it; and at the places where the galleries of communication fall into the envelope are placed strong doors, with loop-holes through them, for musketry, in order to arrest the progress of an enemy, should he force an entrance into the latter.

The most proper place for the magistral gallery does not appear to be precisely determined. Some engineers form it close to the counterscarp, so that the wall of the latter serves for one side of the gallery; by this disposition considerable expense is saved, and complete ventilation may be easily obtained by means of loopholes opening into the ditch. But as, in this situation, the enemy, having penetrated into the gallery, might direct a fire through the loopholes, and might easily form a passage into the ditch by destroying the counterscarp wall, others prefer that it should be executed under the banquette of the covered-way.

A continuous gallery surrounding the place under the foot of the glacis is objectionable on account of the certainty that, in some part of its length, it will be met and destroyed by the working parties of the besiegers: it is therefore preferable that at the extremities of the galleries of communication before mentioned there should be executed short portions only of an envelope gallery; from which portions the listeners may be carried towards the front. The galleries leading from the magistral to the envelope are nearly parallel to, but they ought not to be immediately under, the ridges and gutters of the glacis, lest those lines should serve the enemy as indications of the positions of the galleries, and enable him easily to find them; and as a man working under ground may be heard at a distance of ninety feet from him, it follows that the listening galleries ought not to be more than twice that distance from each other, lest the enemy's miner should pass between them unperceived.

The roofs of galleries may be from fifteen to twenty feet below the level of the natural ground.

The galleries executed by the besiegers are usually carried out from a shaft sunk vertically in the ground; and they are either parallel or inclined to the horizon, according to circumstances. When the soil is loose the sides and roof are lined with planks, which are retained in their places by rectangular frames of timber placed at intervals from each other across the gallery; and it is recommended that the frames should be perpendicular to the direction of the length of the gallery, even when the latter is inclined to the horizon.

The galleries of the besiegers are usually four feet six inches high, and three feet wide; and when their length exceeds 150 feet, the air in them being unfit for respiration, it becomes necessary to ventilate them by bellows or otherwise. [MINE, MILITARY.]

GALLEY (*galère* in French, *galèra* in Italian and Spanish), a large-sized vessel propelled by oars and sails, which was much in use in the Mediterranean until the end of the eighteenth century. It carried two masts with lateen sails, was long and narrow, and drew but little water; it was therefore calculated for coast navigation, and for making the shore in shallow water; and by means of its oars it had a great advantage, in the dead calms so frequent in the Mediterranean, over sailing vessels, an advantage in which it has been effectually superseded by the introduction of the steam-boat. Even long before that invention the use of galleys as a naval force had been given up by France, their construction rendering them unfit for long navigation, and for encountering the waves of the ocean. The Knights of Malta, Naples, the Pope, and other Italian states, were the last to continue the use of galleys for the purpose of coping with the Barbary privateers, whose vessels, although of a similar description, were generally smaller and unable to resist the large and well-disciplined galleys of the Christian powers. The largest galleys were 166 feet long and about 32 wide, with 52 oars. The rowers, who were generally convicts or Turkish prisoners, with chains to their feet, sat on benches on the deck. The ship carried a 24-pounder and two 8-pounders. (See a description and plate of a large-sized galley in the *Dictionnaire de Marine*, article *Galère* in the *Encyclopédie Méthodique*.)

The galleys appear to have been an imitation of the antient triremes, and they retained the antient names for several parts of the rigging, such as 'antenna,' &c. The felucca is a kind of small galley. [FELUCCA.] The Venetians had a sort of large galleys, with a very lofty poop, called 'Galeazza.'

GALLEY SLAVES (*galériens* in French, *galeotti* in Italian), is the name given to criminals condemned to hard labour, who formerly used to be employed as rowers on board the galleys, but now are employed chiefly in the docks and military harbours of France, Spain, and Italy, where they exhibit an assemblage of misery, filth, and vice which is a reproach to the criminal legislation of those countries. [BAGNIO.]

GALLIA. [FRANCE.]

GALLIARD (*Gagliarda*, Ital.), a lively dance in three-crotchet time, which had its origin in Rome, but has fallen into disuse.

GALLIC ACID was the last discovery of Scheele. It exists in most astringent vegetables, but principally in the gall-nut, and hence its name. In this it is mixed with ellagic acid, and with tannic acid, or the tanning principle. Many processes have been proposed for obtaining gallic acid: the simplest is that of reducing galls to coarse powder, and digesting them in about four times their weight of water for several days. The strained solution, when exposed to the air, deposits the gallic acid in small crystals in a short time, and continues to do so for a considerable period. A large portion of the acid exists ready formed in the gall-nut, and by some substance which appears to act as a kind of ferment a further portion of the acid is also formed by the action of the air. It has indeed been supposed that the tannic acid is by oxidation converted into the gallic, and from this source more of the gallic acid may probably be formed. The crystals are sometimes perfect though small, and of a brown colour; they are rendered perfectly colourless by digesting and dissolving in hot water with animal charcoal, which has been treated with hydrochloric acid to dissolve its phosphate of lime; when the colourless solution is sufficiently evaporated, slender prismatic colourless crystals are obtained, the primary form of which is an oblique rhombic prism. The taste of gallic acid is slightly sour and astringent: the solution reddens litmus paper. When exposed to a temperature of above 250° the crystals lose their water and effloresce. Gallic acid is soluble in about 100 times its weight of cold water, and very soluble when it is boiling; it dissolves also in alcohol and in æther.

Gallic acid combines with bases to form salts, which are termed *gallates*; these will be considered, when important, under their respective bases; we merely add that on protosulphate of iron it has scarcely any action, but with the persulphate of iron it produces a deep blue-black precipitate, which is the principal colouring matter of writing-ink. The gallates of ammonia, potash, and soda are soluble in water; but most of the metallic gallates, strictly speaking, are insoluble: gallic acid in the form of tincture of galls is much employed as a chemical *re-agent*; but part of its effect is owing to the presence of tannic acid, which is well known to precipitate solutions of albumen and gelatin, which gallic acid, when pure, does not.

Anhydrous gallic acid, according to Pelouze, is composed of

Three equivalents of	Hydrogen	. . .	3
Seven „	Carbon	. . .	42
Five „	Oxygen	. . .	40
	Equivalent		85

In the crystalline state it contains water, and is composed of

One equivalent of	Anhydrous Gallic Acid .	85
One „	Water	9
	Equivalent	94

When gallic acid is heated it is, as already noticed, rendered anhydrous, but at higher temperatures it is converted into PYROGALLIC ACID and MELOGALLIC ACID. At a red heat it is decomposed and totally dissipated.

GALLI'COLÆ, a family of Hymenopterous insects of the section Pupivora. Distinguishing characters:—posterior wings having but one nervure; anterior wings with two brachial cells, a radial cell of a triangular form; two or three cubital cells, of which the second (where there are three) is very small, and third large and bounded by the apical margin of the wing; antennæ of equal thickness from the base to the apex (or with the latter portion slightly thickened) and consisting of from thirteen to fifteen joints. The males with one joint more to the antennæ than the females. Palpi long; the maxillary usually four-jointed, and the labial three. Ovipositor lodged in a groove on the underside of the body.

Latreille enumerates but three genera belonging to this family. Those which have the antennæ filiform, the abdomen much compressed, the radial cell of the wing long and narrow, the two brachials very distinct, and the two first cubitals small, constitute the genus *Ibalia*.

The species of the next genus (*Figites*) have the abdomen thickened and rounded above, the antennæ gradually thickened towards the apex, but one brachial cell, the radial very distant from the apex of the wing, and the second cubital wanting.

In the genus *Cynips* the abdomen is similar to the last, but the antennæ are filiform; there are three cubital cells to the wing, the first of which is large: the radial is elongated, and there is but one complete cell at the base of the wing. [GALLS.]

GALLIE'NUS, PUBLIUS LICINIUS, son of the emperor Valerianus, was made Cæsar and colleague to his father A.D. 253. He defeated in a great battle, near Milan, the Alemanni and other northern tribes which had made an irruption into North Italy, and gave evidence of his personal bravery and abilities. He was also well informed in literature, and was both an orator and a poet. When Valerianus was taken prisoner by the Persians, A.D. 260, Gallienus took the reins of government, and was acknowledged as Augustus. He appears to have given himself up to debauchery and the company of profligate persons, neglecting the interests of the empire, and taking no steps to effect the release of his father from his hard captivity, in which he died. The barbarians attacked the Empire on every side, revolts broke out in various provinces, where several commanders assumed the title of emperor, whilst Gallienus was loitering at Rome with his favourites and mistresses. Yet now and then he seemed to awaken from his torpor, at the news of the advance of the invaders, and putting himself at the head of the legions, he defeated Ingenus, who had usurped the imperial title in Illyricum. But he disgraced his victory by horrible cruelties. [BYZANTIUM.] Meantime Probus, Aurelianus, and other able commanders, were strenuously supporting the honour of the Roman arms in the East, where Odenatus, prince of Palmyra, acted as a useful ally of the Romans against the Persians. Usurpers arose in Egypt, in the Gauls, in Thrace, in almost every province of the Empire, from which circumstance this period has been styled the reign of the thirty tyrants. At last Aureolus, a man of obscure birth, some say

a Dacian shepherd originally, but a brave soldier, was proclaimed emperor by the troops in Illyricum, entered Italy, took possession of Milan, and even marched against Rome while Gallienus was absent. Gallienus returned quickly, repulsed Aureolus, and defeated him in a great battle near the Adda, after which the usurper shut himself up in Milan, where he was besieged by Gallienus, but during the siege the emperor was murdered by some conspirators, A.D. 268. He was succeeded by Claudius II. Trebellius Pollio has written a history of the reign of Gallienus. [AUGUSTA HISTORIA.] See also Zonaras, Aurelius Victor, and Eutropius.

Coin of Gallienus.

British Museum. Actual size. Copper gilt. Weight, 223 grains.

GALLI'NÆ, Gallinaceous Birds, the fifth order of the class *Aves*, according to Linnæus, who thus characterizes it: *Bill* (a reaping sickle, *Harpa colligens*) convex: the upper mandible arched over the lower; *Nostrils* overarched by a cartilaginous membrane. *Feet* formed for running, the toes rough below. *Body* sebaceous, muscular, delicate (*purum*). *Food*, grain collected on the earth and macerated in the crop (*ingluvies*). *Nest* artless and placed on the ground; eggs numerous; food pointed out to the young by their parent. Polygamous. Analogous to the order *Pecora*, in the class *Mammalia*. [RASORES.]

GALLINSECTA (Latreille), COCCIDÆ (Leach), a family of insects placed by Latreille and others at the end of the Homoptera. These insects apparently have but one joint to the tarsi, and this is furnished with a single claw. The males are destitute of rostrum, and have two wings, which when closed are laid horizontally on the body: the apex of the abdomen is furnished with two setæ. The females are apterous, and provided with a rostrum. The antennæ are generally filiform or setaceous.

The insects belonging to this family live upon trees or plants of various kinds: they are of small size, and in the larva state have the appearance of oval or round scales, which are closely attached to the plant or bark of the tree they inhabit, and exhibit no distinct external organs. At certain seasons, when about to undergo their transformation, they become fixed to the plant, and assume the pupa state within the skin of the larva. The pupa of the males have their two anterior legs directed forwards, and the remaining four backwards; whereas in the females the whole six are directed backwards. When the males have assumed the winged or imago state, they are said to issue from the posterior extremity of their cocoon.

In the spring time the body of the female becomes greatly enlarged, and approaches more or less to a spherical form. In some the skin is smooth, and in others transverse incisions or vestiges of segments are visible. It is in this state that the female receives the embraces of the male, after which she deposits her eggs, which are extremely numerous. In some the eggs are deposited by the insect beneath her own body, after which she dies, and the body hardens and forms a scale-like covering, which serves to protect the eggs until the following season, when they hatch. The females of other species cover their eggs with a white cotton-like substance, which answers the same end.

Upwards of thirty species of the family Coccidæ, or Gallinsecta, are enumerated in Mr. Stephen's Catalogue of British Insects; several of these however have undoubtedly been introduced with the plants they inhabit, and to which they are peculiar.

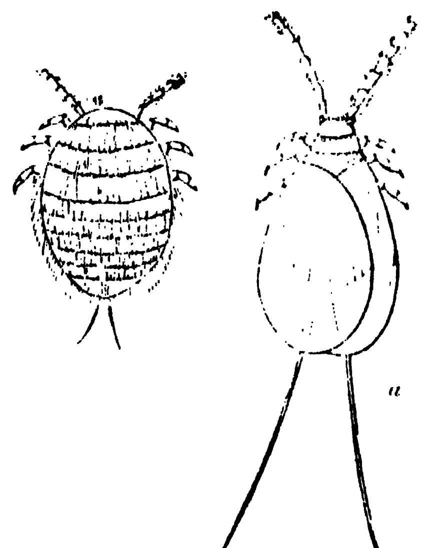
Many of the exotic Cocci have long been celebrated for the beautiful dyes they yield. The Coccus Cacti of Linnæus may be mentioned as an instance. The female of this species is of a deep brown colour, covered with a white powder, and exhibits transverse incisions on the abdomen. The male is of a deep red colour, and has white wings.

This insect, which when properly prepared yields the dye called cochineal, is a native of Mexico, and feeds upon a particular kind of Indian fig, which is cultivated for the express purpose of rearing it. [COCHINEAL.]

Coccus Ilicis, an insect found abundantly upon a small species of evergreen oak (*Quercus coccifera*), common in the south of France, and many other parts, has been employed to impart a blood red or crimson dye to cloth from the earliest ages. (*Introduction to Entomology*, by Kirby and Spence, vol. i., p. 319.)

Coccus Polonicus is another species which is used in dyeing, and imparts a red colour. It is now chiefly employed by the Turks for dyeing wool, silk, and hair, and for staining the nails of women's fingers. (Kirby and Spence, vol. i., p. 320.)

But we are not only indebted to the Coccus tribe for the dyes they yield: the substance called Lac is also procured from one of these insects (the *Coccus Lacca*). This species inhabits India, where it is found on various trees in great abundance. 'When the females of this Coccus have fixed themselves to a part of the branch of the trees on which they feed (*Ficus religiosa* and *Indica, Butea frondosa*, and *Rhamnus Jujuba*), a pellucid and glutinous substance begins to exude from the margins of the body, and in the end covers the whole insect with a cell of this substance, which when hardened by exposure to the air becomes lac. So numerous are these insects, and so closely crowded together, that they often entirely cover a branch; and the groups take different shapes, as squares, hexagons, &c., according to the space left round the insect which first began to form its cell. Under these cells the females deposit their eggs, which after a certain period are hatched, and the young ones eat their way out.' (Kirby and Spence, vol. iv., p. 142.)



Coccus Cacti, magnified.

a, the male. *b*, the female.

GALLI'NULA. [RALLIDÆ.]

GALLIOT, a strong-built flat-bottomed vessel of a peculiar construction, used as a bomb-ship to fire against forts or batteries on the coast. The largest are of the burthen of 400 or 500 tons, and above 100 feet in length. See account and plate of the same in the *Dictionnaire de Marine*, in the *Encyclopédie Méthodique*, art. 'Galiotte.' Galliot is also a kind of small galley or large felucca, used chiefly in the Mediterranean, especially by the Barbary corsairs. [GALLEY.] The Dutch, Swedes, and other northern nations have a sort of merchant-ship which they call Galliot, heavy and clumsily built, but strong of timber, rounded both fore and aft, and of the burthen of from 200 to 300 tons.

GALLI'POLI, the antient Callipolis, in the Chersonesus of Thrace, a town of European Turkey, situated at the entrance of the Hellespont, now called the Straits of Gallipoli, on the side of the Propontis. It lies nearly opposite to Lampsaki, the antient Lampsacus, on the Asiatic side of the channel, which is here about two

miles in breadth. Gallipoli occupies a considerable space, but is not peopled in proportion to its extent. It has an extensive bazaar, with domes covered with lead, and the shops are tolerably supplied. This town is interesting as being the first place in Europe where the Turks acquired dominion. Tournefort gives an account of its history, and of the legends of the Osmanlis in relation to their early conquest. The town now contains 'a mixed population of Turks, Greeks, Armenians, and Jews, somewhat exceeding 20,000, which some travellers have swelled to 60,000. Its trade consists in corn, wine, and oil. In the vicinity of the town are some fertile patches of land cultivated by Greeks, but beyond them you get into a desert.' (Macfarlane's *Constantinople in* 1828.) Excellent water-melons grow in the neighbourhood of Gallipoli. Consuls or vice-consuls of several European powers reside in this place.

GALLIPOLI. [OTRANTO, TERRA DI.]

GALLON, an old English measure of capacity. The Latin of the middle ages is *galo, galona, jalo, lagena*, &c. Dr. Bernard thinks the latter is the original. Ducange cites an old assize of David of Scotland, in which it is said the *lagena* should contain twelve pounds of water, namely, four of sea water, four of still water, and four of running water. But that various gallons were used is evident from statutes of Henry III. and later kings, in which it is enacted that ale, wine, and corn shall be measured by the same gallon, containing eight troy pounds of dry wheat from the middle of the ear. These statutes produced no effect, and distinct gallons for wine, ale and beer, and corn and dry goods, continued in use until the act of 5 Geo. IV., cap. 74, which came into operation May 1, 1825.

By statutes of 1689 and 1697, the wine gallon was declared to contain 231 cubic inches. But in 1688, by an experiment at which Flamsteed, Halley, and others (among whom was Ward, author of the 'Young Mathematicians' Guide,' who relates the circumstance) were present, it was very distinctly proved that the sealed gallon at Guildhall (which was the *usual* standard) contained only 224 cubic inches. 'However,' says Ward, 'for several reasons it was at that time thought convenient to continue the former supposed content of 231 cubic inches.' The fact was, that the Guildhall gallon was an incorrect copy of the old Exchequer standard, placed in a more accessible locality. Previously to this, Dr. Bernard had stated his full conviction, from the measurements of predecessors whom he cites, that the said gallon contained 223·549 cubic inches; the agreement of these two experiments leaves no doubt as to their accuracy. By the act of the 5th of queen Anne, the wine gallon of 231 inches was made the standard; and a gallon was accordingly constructed for the Exchequer, which the Committee of the House of Commons, in 1758, found to contain $231\frac{1}{10}$ cubic inches. The account of the experiment in 1688 was preserved, and is cited by the Committee.

The ale gallon was measured in 1700 or thereabouts, and found to contain 282 cubic inches. Ward imagines that this gallon was meant to bear the same relation to a pound avoirdupois which the wine gallon did to a pound troy; and 231 is to 282, very nearly as 5760 to 7000, the latter being the proportions of the two pounds. But if the wine gallon were only 224 cubic inches, then the ale gallon should have been $272\frac{1}{4}$; or, as we shall see, the corn gallon much more nearly coincides with the hypothesis.

The corn gallon was thought, in the middle of the last century, to contain exactly $272\frac{1}{4}$ cubic inches. Dr. Bernard, on the same authorities, states it to have been determined at 266 cubic inches; and the statute of 1697, which declares that a round corn-bushel must be 8 inches deep, and $18\frac{1}{2}$ inches wide, had in fact fixed the gallon at $268\frac{6}{10}$ cubic inches.

The imperial gallon, as settled by the act of Geo. IV., is to contain 10 pounds avoirdupois of distilled water, of which it is declared that 252·458 grains fill a cubic inch: consequently, the imperial gallon contains 277·274 cubic inches; being very nearly a mean between the old ale and (previously to 1697) corn gallon. According to the parliamentary standards, then, we have

Old wine gallon, 231 cubic inches.
Old corn gallon, 268·6 do.
New imperial gallon, 277·274 do.
Old ale gallon, 282 do.

GALLOWAY (called by the Latin writers of the middle ages Gallovidia, from the Irish who once inhabited it) is an extensive district in the south-west of Scotland, comprising the shire of Wigtown and stewartry of Kirkcudbright, together with part of the shires of Ayr and Lanark. It is bounded by the sea, the firth of Solway, and the river Nith, and is divided into Upper and Lower Galloway. It appears to have been independent until after the overthrow of the Picts, when the Scottish monarchs assumed a feudal superiority over the lords of Galloway. The lordship subsequently descended to the family of Douglas, with whom it remained till 1455, when, in consequence of the rebellion of James, earl of Douglas, the estates became forfeited to the crown. The extensive line of coast is so conveniently indented with lochs, bays, and navigable rivers, that were it not for the scarcity of coal it would be one of the most eligible situations in the island, in point of natural advantages, for a trading or manufacturing district. At the south-western extremity is the well-known promontory called the Mull of Galloway, where there are some excellent quarries of whinstone, freestone, and slate. The general appearance of the district is rugged and mountainous, producing little else than pasturage for sheep and cattle, which are bred in large numbers, principally for the supply of the English market. The small horses known by the name of Galloways are also bred here. [WIGTOWN; KIRKCUDBRIGHT; &c.] (Camden's *Britannia; Statistical Acct. of Scotland; Beauties of Scotland;* &c.)

GALLS are the result of a morbid action excited in the leaf-buds of several species of the genus Quercus, or oak, occasioned by an insect, Cynips Quercus, depositing its ova in the bud. Such buds, instead of elongating and becoming branches, undergo a peculiar transformation, and enlarge into a globular figure, so as to constitute a fit nidus for the future larva.

The galls of commerce are chiefly those which occur on the Quercus infectoria (Ollivier). They vary in size, from that of a pea to that of a nutmeg. The surface has irregular elevations or lines, with the interspaces generally smooth. The colour is white or yellow in one variety; green, grey, or black in another. The white variety, which is the largest, often has a hole in the substance of the shell, by which the larva has escaped. This kind is the least powerful and least esteemed. The best galls come from Aleppo and Smyrna, but are often mixed with those from Syria and Cyprus. In 100 parts of Aleppo galls Sir H. Davy found gallic acid, 6·2; tannin, 26; gum and insoluble tannin, 2·4; lime and other salts, 2·4; woody fibre, 63. Braconnot also found ellagic acid. Galls are devoid of smell, but have a disagreeably bitter taste, with a powerfully astringent action. The whole of their soluble matter is yielded to forty times their weight of boiling water; æther dissolves about half their weight, alcohol considerably more.

The infusion possesses all the valuable properties of the gall, as does an alcoholic tincture; but decoction is an objectionable preparation. For internal use the infusion is preferable to the powder, which, like all substances containing much woody fibre, irritates the stomach. Galls may be employed in powder to form an ointment, which with opium and camphor is of great service in painful hæmorrhoids. As a tonic in intermittent fever, and as an astringent in hæmorrhagic or other discharges, galls are occasionally employed. But the most extensive use is made of them in the arts, and as a chemical test.

GALLUS (Zoology). [PHASIANIDÆ; POULTRY.]

GALUPPI, BALDASSARE, a composer of great reputation in his day, very commonly known by the name of Buranello, from having been born in the island of Burano, near Venice. He was a disciple of the famous Lotti, and his first opera was produced at Venice in 1722. In the middle of the last century Galuppi's works were highly esteemed, and some of his compositions would now, if properly arranged, find abundant admirers among the lovers of good dramatic music.

GALVA'NI, ALOYSIUS (Lewis), was descended from a respectable family of Bologna, which had produced several distinguished men of letters. He was born in that town in 1737, and in consequence of a religious turn of mind which he strongly displayed during his childhood, was at first designed for holy orders and to take the monastic vows. He afterwards changed his intentions while studying at the university of Bologna, and married the daughter of his tutor Galeazzi, who was a professor at that university, and with whom he had for some time lived on terms of close intimacy. His degree of M.D. was con-

ferred in 1762, and his fame had so far increased that he received the appointment of Lecturer on Medicine at the Institute of his native town. In the 'Memoirs' of this body we find contributions on various medical subjects by Galvani. He also published separately 'Observations on the Urinary Organs,' and 'On the Organs of Hearing in Birds;' but an accidental circumstance, of which he availed himself with acuteness and much judgment, introduced him to a novel subject, the announcement of which at that time excited deep attention throughout Europe, and gave birth to a new and fruitful branch of Physics, which yet retains in all countries the name of its first observer.

During his temporary absence from his house, his wife, who was about to prepare some soup from frogs, having taken off their skins, laid them on a table in the studio near the conductor of an electrical machine which had been recently charged. She was much surprised, upon touching them with the scalpel (which must have received a spark from the machine), to observe the muscles of the frogs strongly convulsed: she acquainted him with the facts upon his return; Galvani repeated the experiment, and found that it was necessary to pass a spark or communicate electricity through the metallic substance with which the frogs were touched. After having varied the experiment in several ways, he was led to conclude that there existed an Animal Electricity both in nerves and muscles, and some future experiments appearing favourable to that erroneous inference, he seems to have clung to that opinion during the remainder of his life, notwithstanding the experiments of Volta and others, which showed at least that the moisture on the surface of the frog acted as a conductor.

The following circumstance was that on which Galvani most relied for the accuracy of his opinion. Having seen the effects of the direct electricity of the machine on the muscles of frogs, and that by exposing only the spine, legs, and connecting nerves to the electrical action a very small charge was sufficient to produce the convulsive motions: he imagined that the atmospheric electricity, though of feeble tension, might be sufficient to produce like results. He therefore suspended some frogs thus prepared by metallic hooks to iron railings, when he observed that the convulsed motions depended on the position of the frog relative to the metals. The same phenomenon led Volta to an opposite conclusion, and a war of opinion for some time divided philosophers; into this dispute it will not be necessary now to enter. Ultimately Volta triumphed over Galvani, but failed to convince him.

The work in which Galvani developed his views relative to this new class of phenomena was published in 1791, under the title 'Aloysii Galvani de viribus Electricitatis in Motu Musculari Commentarius,' in which he infers that the bodies of animals possess a peculiar kind of electricity, by which motion is communicated by nerve to muscle, and in these experiments he regarded the metals acting only as conductors between these substances, which he thought accounted for the observed contractions of the muscle, in the same manner that the dissimilar electricities on the interior and exterior surfaces of a Leyden jar reunite with explosion through a metallic conductor. If the reader is desirous to make an experiment of this kind, let him separate the head and upper parts of the body of a frog, remove the skin from the legs, clear out the abdomen, separate the spine below the origin of the sciatic nerves, that they alone may form the connection with the legs; then envelop the spine and nerves with tinfoil, and placing the legs on silver, complete the circuit by making the two metals touch: the convulsive motions will be instantly produced.

Philosophers in other countries hastened to repeat and vary these experiments. Fowler found that when the circuit was completed by the eye, the contact of the metals produced the sensation of a flash of light; and Robinson remarked the acid taste when the tongue was used between the metals, to which he also attributed the peculiar taste of porter when drank from a pewter vessel. It may be added that Sulzer, as early as 1767, described the influence upon taste caused by the contact of different metals with each other and with the tongue; results of this kind were pursued with more eagerness than nature seemed willing to gratify, and the influence of Galvanism on the senses of smelling and hearing, which Cavallo thought he had observed, have not been verified, or rather, have been disproved.

The interesting researches of Galvani having acquired such extensive notoriety (See *Phil. Trans.* 1793), introduced him to the pleasures and the troubles of an extensive correspondence. In 1797 Galvani made a voyage along the shores of the Adriatic for the purpose of confirming his notions on animal electricity by experiments on the Gymnotus, from which he concluded that the brain contributed to produce the observed effects. His wife, who had proved herself a sensible and an affectionate woman, died soon after his return, a loss which he seems to have felt very severely. His afflictions were increased during the French occupation of Italy; he was expelled from the offices which he held, because he refused the prescribed oaths, when Bologna formed a part of the Cisalpine Republic. His pecuniary circumstances at this time, as well as his health, were in a very low state, and shortly after his restoration to his former offices he died, in 1798.

In two years after the death of Galvani, his nephew Aldini produced convulsive motions of the kind above noticed in the body of a convict who was hanged at Newgate.

GALVANISM. This department of electricity takes its name from Galvani; but its infant progress was due in a much greater degree to his contemporary Volta, by whom piles were first constructed for increasing the intensity of the electricity produced by a single pair of plates. The production of electricity in this case arises from the action of the acid in the cell between two plates of dissimilar metals, that which is the more oxidable giving out positive electricity, as explained under ELECTRO-DYNAMICS. The forms in which the piles have been constructed are various, and the number of plates is adapted either to the quantity or intensity of electricity which may be desired. When quantity with a feeble tension is requisite, a single pair of plates, such as zinc and copper, with extensive surfaces, separated by very dilute acid, will answer; but with a system of pairs of plates, where the copper of the first pair *conducts* its electricity to the zinc of the second, and so on, the quantity and intensity are increased with the number of the plates. In some constructions, as Ritter's dry piles, the plates are simply laid on each other, those of each pair being separated by moistened paper; in others the plates lie parallel in a trough of baked wood, by which means the cells are easily filled and emptied. In the *couronne des tasses* of Volta the plates are placed circularly or in a bowl shape; while in Hare's Calorimotor there is merely one zinc plate and one copper twisted into a great number of coils, which form increases the intensity, as may be seen from the article ELECTRO-DYNAMICS. This construction has been much employed by Pepys, Faraday, and others.

The electricity thus produced is of the same nature as that given by the common machine; the only difference being that the mode of producing galvanism is continuous, that is, when in any way discharged it is immediately reproduced by the oxidation of the zinc; and hence many galvanic phenomena have been successfully imitated by a series of sparks of ordinary electricity. When the positive and negative wires are made strictly to communicate by metallic conductors, the combination of the opposite electricities causes all phenomena analogous to those produced by the ordinary machine to cease, but gives birth to the electro-dynamic and electro-magnetic phenomena. [ELECTRO-MAGNETISM.] But when the wires from the opposite poles of the battery are only brought sufficiently near that the current may pass through an interposed substance, or when the circuit is completed by imperfect conductors, the physical changes which the interposed substances undergo constitute the phenomena of galvanism. It may be observed that the relative conductibility of substances for Voltaic electricity is nearly the same as for common, but the alterations produced by the former in the temperature and internal nature of the substances through which the current is admitted interfere in some degree with that order of conductibility.

The deflagration of metals is effected by beating them into thin leaves, which are then interposed between the extremities of the positive and negative wires of the battery, brought within a quarter of an inch of each other: they will then burn with a beautiful light, but which is of different colours in different metals. Thus—zinc gives a white light with a reddish border; copper, a bluish white light, and throws out red sparks; lead, a purple light; gold leaf, a beautiful white light tinged with blue.

But if the interposed substances, instead of being laminæ, be of small irregular forms, or wire-shaped, their temperature rises rapidly as the electric current permeates them. Steel

burns, iron wire dissolves in globules, while charcoal produces a light of such dazzling brilliancy as to fatigue the eye, a property which has been happily seized by employing it in the solar microscope; yet this heat and light are independent of the ambient medium, no oxygen is consumed, and the attenuation of the air rather adds to than diminishes the light. As for the apparent diminution of this intense light when the charcoal is immersed in water, it is attributable to the imperfect conductibility of the latter medium: a thermometer placed in water, in which the wires are immersed, will rise even to the boiling point. Mr. Children has given a list of the order of facility in which substances thus acquire a red heat, and has succeeded in fusing the oxides of molybdenum, tungsten, uranium, &c., but found ruby, sapphire, silex, quartz, &c., more intractable. It is obvious that, in the estimation of such an order, we must take an account of the mass heated, and of the extent of its surface which is liable to cool by contact, radiation, or both; and lastly, of the loss of conductibility due to the increase of temperature of the substance interposed. Æther, alcohol, &c., may be inflamed, and gunpowder exploded, by making the discharge through charcoal points.

Sir Humphry Davy avoided the increase of temperature in the wires through which the current was discharged by taking them of a length sufficient to discharge the number of pairs of plates employed in the pile, and thus found that the length of wire in this case is inversely proportional to the number of double plates. The diminution of conductibility due to increase of temperature he exhibited by a platinum wire made red-hot by the galvanic current; for when he raised one part of it to a white heat by means of a blowpipe, the heat in the other parts of the wire became immediately reduced. The order of heating in metals, beginning from that most susceptible, which he has given, is as follows: —iron, palladium, platinum, tin, zinc, gold, copper, silver.

The decomposition of water by the battery is effected by bringing the points of the positive and negative wires very near each other under water, inverted glasses being placed over them to collect the gases which are evolved. If the wires be not oxidable, then oxygen gas will be formed at the extremity of the positive wire, and hydrogen at the negative, in the same proportions in which they constitute that liquid; but if oxidable, then the positive wire will be covered with an oxide, while the negative wire still produces hydrogen gas. In general oxygen and chlorine are found at the positive pole, and the other gases at the negative; but we are not to suppose that oxygen only is disengaged by one wire, and hydrogen only by the other; for the particles of water in contact with the ends of either wire are strictly decomposed into their constituent gases, but the oxygen formed at the negative wire is transferred to the positive, and the hydrogen at the positive is transferred to the negative.

The chemical analysts were at first somewhat puzzled at finding foreign products, when producing decomposition by galvanism; soda, which was sometimes found, was due to the decomposition of small portions of the glass in which the experiments were made, and muriatic gas to vegetable substances employed occasionally, as wet cotton-thread, when the liquid was contained in separate vessels having only this mutual communication.

When neutral salts were held in solution and exposed in the same manner to the galvanic action, their alkaline bases were found at the negative wire, and the acid at the positive: thus zeolite was decomposed into soda and lime; common salt into solution of soda and sulphuric acid; while the metallic solutions gave their crystals and oxides to the positive pole, and transferred the acids to the negative. Davy made the remarkable discovery that this transfer took place without any combination being effected with the parts of the medium traversed, even when the latter had a great affinity for the elements which passed through it. He arranged three cups, in the first of which was a solution of litmus (a well-known chemical test), in the second a similar solution, and in the third sulphate of soda. The positive wire was immersed in the first cup, the negative in the third; and the intermediate was connected with the two extreme cups by a moistened thread, so as to complete the circuit: the result was, that the solution of litmus in the positive cup became red, indicating the transfer of the acid from the third cup, while the similar solution in the intermediate cup underwent no change, clearly showing that the acid in its transfer did not combine with the solution through which it passed. Similarly, upon reversing the poles, a green was produced in the first cup, while the middle still remained unaffected. But he soon recognised that there was an exception to this, namely, when the transmitted substance and the medium combine so as to form an insoluble compound; for when it has thus acquired a greater specific gravity than the medium, it is necessarily drawn out of the line of transference; and if by mechanical means it should be preserved in it, the transfer will go on as before.

It may be observed generally, with respect to chemical decompositions effected by galvanism, that it is quantity rather than intensity which is requisite, and that the metals, alkalies, and earthy bases are transferred to the negative pole; the acids, oxides, and chlorides to the positive. By the successive labours of Davy, Wollaston, Brande, Gay-Lussac, Berzelius, &c., different substances which had before been supposed simple, as soda, potash, lime, barytes, strontytes, magnesia, zircon, &c., were analyzed by this powerful instrument; and though silex, alumina, &c., offered great resistance to its application, and the metallic bases were with difficulty restrained from again combining with oxygen, still in the majority of cases the analysis has been successful. The same method was applied by Brande to fluids containing albumen, when albumen and alkali were found at the negative pole, albumen and acid at the positive; he also found that though it remained fluid with a weak battery, when a stronger one was employed it was separated in a coagulated form.

Experiments of the same nature have been recently made by Mr. Golding Bird, whose results do not agree with those obtained by Brande. He used for his battery the Voltaic form, a 'Couronne de Tasse,' of thirty small plates, excited only by a weak solution of salt, and first operated on liquid albumen in a state of non-combination. Putting serum of blood into a glass vessel, and having introduced the wires of the battery, a cloudy deposition took place near the positive wire without adhering to it. The experiment being next made with two vessels connected by moistened cotton, coagulation took place in the positive vessel, while none occurred in the negative; after a time the contents of the former had an acid taste, and of the latter a caustic alkaline flavour: when all in the positive vessel was coagulated by the galvanic action, he found there hydrochloric acid mixed with chlorine, and the alkali in the negative vessel. He has given also an explanation of the causes of the difference in Brande's results.

An interesting class of experiments are due to Mr. Crosse on the employment of electricity, in a state of high tension, to form mineral and other substances. There is a cavern near Broomfield, of which the vault is covered with arragonite and carbonate of lime and fine crystals. The water which drips from this vault holds in solution ten grains of carbonate of lime and a little sulphate of the same to each pint. A glass filled with this water was submitted to the action of a battery consisting of 200 pairs of plates, and at the expiration of ten days the negative pole was found to have formed rhomboidal crystals of carbonate of lime, accompanied by some gas-bubbles, and in less than a month after the wire was covered with regular and irregular crystals, whence it follows that the bi-carbonate was decomposed into carbonate and carbonic acid gas. He also let the water drop on a piece of brick subjected to a current from 100 five-inch plates, the brick being supported by a funnel which conducted the water into a vessel below: after four or five months the brick near the negative pole of the battery was covered with carbonate of lime, while near the positive pole were disposed prismatic crystals of arragonite: and the same experiment being repeated with fluosilicic acid, regular hexahedral pyramids similar in all respects to quartz were obtained: those which were left in a dry place acquired sufficient hardness to scratch glass; the others had not that power, and gradually lost their transparency. In his varied experiments of this nature he has succeeded in forming, by means of the galvanic battery, the following minerals:—carbonate of lime; arragonite; quartz; protoxide of copper; arseniate of copper, and its blue and green carbonates; phosphate of copper; carbonate of lead; chalcedony, &c., upon which Becquerel remarks, in the last-published volume of his 'Experimental Electricity,' 'Nearly all these substances we have obtained these dozen years with the *simple* electro-chemical apparatus.'

Experiments on the increase of the chemical power of the galvanic apparatus, compared with the increase of the number of plates, have been made by Davy, Gay-Lussac, and Thénard; but they disagree. We shall therefore now pass on to a brief notice of the physiological effects produced by galvanism, from which we must exclude any account of the animalculæ observed by Mr. Crosse in the solutions employed in his recent experiments, pending the further progress of those highly interesting researches, and in the absence of any similar result in the experiments which Mr. Faraday has made with the same object.

In the life of Galvani there is an account of the convulsive motions to which denuded frogs are subject when the nerve and muscle form part of the galvanic circuit. In order that an individual may receive a shock from a battery, it is advisable to moisten the hand, because the dry cuticle is a bad conductor of electricity: then, on touching one of the wires of the battery with a metallic rod, the shock will be received and felt in the wrists, arms, or shoulders, according to the intensity of the current; or a continued sensation, resembling the piercing of a very fine needle, will be perceived by dipping the finger in a dish containing a little water in which the wires of the battery are inserted in the same line with the finger. In both cases, if the nerves are denuded by a cut, the sensation is painful, and the pain will remain some time before it subsides. In some experiments of this kind Humboldt brought on an inflammation by applying the current to a cut. Volta has asserted that the negative wire communicates the greater pain.

A flash of light is perceived by covering the bulb of the eye with tinfoil and forming a metallic communication thence with the mouth, for instance, with a silver spoon; also Berzelius found an acid taste on dipping the tongue into a zinc vessel containing water, which was placed on a silver stand, by touching the silver with his hand so as to complete the circuit. When the negative current is communicated to the taste, it is caustic and alkaline.

When the battery is applied to a nerve of a person recently dead, and the circuit is completed, several violent motions ensue, dependent on the relative position of the nerve and muscle: thus, when the wire communicates with the phrenic nerve, the muscles of respiration are set in motion; when from the ulnar nerve to the spinal marrow is included in the circuit, the fingers are set in quick motion, and so on. Fishes are still more susceptible of this electric action than animals, and strong convulsive motions will be exhibited by a live flounder placed on a zinc dish and having a piece of copper or silver on its back, as soon as the two metals come in contact: similar effects take place with leeches, worms, and amphibious animals.

It was thought by Volta that the involuntary muscles, such as the heart, could not be thus excited, but experiment has decided against him.

When the secretion was suspended by cutting the eighth pair of nerves, Dr. Philip and several French anatomists have restored it by establishing a galvanic current through the divided part of the nerves next the stomach.

Intermittent currents have been employed in the experiments of Masson, Peltier, and Delarive. To effect this, M. Masson used a toothed wheel rotating by a cord round it; its axis, supporter, and itself being all metallic: a communication is formed between this wheel and a battery in the form of a helix: the object of the teeth of the wheel is occasionally to suspend the action of the current by making the connecting rod of too great a length; hence, when the wheel is made to revolve, the galvanic current acts and is suspended alternately. By a series of intermitted discharges produced in this manner, M. Masson had the cruel pleasure of killing a cat.

P. Santi Linari drew the electric spark from the gymnotus in the following manner:—he took a glass tube of the shape of a capital U, which he partly filled with mercury; at each end was fixed an iron wire through a wooden button, and which reached very near the mercury. The apparatus being fixed with mastic on varnished wood, the end of the wires were made to touch short platina wires terminated by laminæ of the same metal, intended to make a good communication with the different parts of the electrical fish. When the circuit was formed, a spark visible even in the daylight appeared at the place where the conductors were interrupted. This experiment he has repeated in different forms. (*Biblioth. Univ. de Génève.*)

M. Delarive has lately noticed a remarkable difference of effects in the action of Voltaic and of magneto-electric currents. When the wires of the latter were used for decompositions, but in the form of thin leaves or laminæ, there was but little disengagement of gas, and the more the lamina was plunged, the less was the gas evolved, which was not the case in the common form of the wire: this does not occur in Voltaic electricity; the same experimentalist has sought the quantity of electricity necessary to decompose a given quantity of water, and his result is that the product of the time multiplied by the intensity of the current is constant.

Journal*; *Annales de Chimie*; *Journal de Physique*, 64; Puffendorf, *Annalen.*; Becquerel, *Traité Experimental*; Pouillet, *Physique*; *Reports of the British Association*, &c.)

GALVANISM, in its action on the human system, resembles electricity, yet it is distinguished by certain peculiarities. In its application it can be rendered more continuous and uniform, and may, like electricity, be administered either in shocks, or in a regular flow of galvanic influence through the body. It possesses more power over the chemical actions of the body than electricity, and promotes more completely those processes of decomposition and recomposition which take place in the living frame, as well as the functions of organic life, than common electricity. But the chief distinction consists in the difference of action of the two poles. Each pole excites peculiar phenomena in the organs to which it is applied. This difference is less perceptible when mere shocks are administered, than when a continuous stream of galvanic influence is transmitted from one point to another of the body. The positive pole more particularly influences the muscular and vascular system, while the negative pole more especially affects the nervous system. At the positive pole there is felt the shock, strong movements, a feeling of concentration and contraction, increased warmth and mobility of the part, with gradual diminution of the secretion and sensibility. At the negative pole the pain and sensibility are stronger and more acute, the organ expands, is more irritable, while the muscular action and mobility are lessened. The difference of their action on the secreting powers is best seen by applying the respective poles to a surface which has been recently deprived of its cuticle, such as where a blister has been. The positive pole changes the serous secretion into that of lymph, which at last becomes thready; the part dries and is inflamed. The negative pole causes an abundant secretion of a dark coloured, highly acrid fluid, which excoriates the skin over which it flows: the part also experiences an enduring irritation. Atonic swellings are rendered harder, should they not become inflamed by the positive pole, while frequently by the negative pole they are dispersed and resolved. Notwithstanding the possession of such powerful properties, galvanism has not produced so valuable results in medicine as might have been anticipated. This comparative failure is no doubt to be attributed to errors in the mode of applying it. As the diseases in which it has been recommended are those already enumerated under electricity [ELECTRICITY, MEDICAL USES OF], it is not necessary to repeat them here. It may be proper however to remark, that it was urgently recommended during the prevalence of the Asiatic cholera, but the results were not satisfactory. Like many other powerful agents, it was not used till a very late stage in the complaint, when recovery was almost impossible. It is also to be doubted whether galvanism be at all applicable to cholera, since it appears that the continued application of it causes death, by inducing inflammation of the lungs, in cases of animals where the eighth pair of nerves have been divided, more speedily than where the same nerves have been divided in animals to which the galvanic power was not applied as a substitute for the nervous. Inflammation is the invariable consequence of the application of the positive pole; while the negative pole would cause a flow of acrid secretion which could not benefit the patient. The identity of electricity, whether common or galvanic, with the nervous power, is much to be questioned. (See controversy between Dr. W. Philip, Dr. Williams, and others, in *Medical Gazette*, vol. xvii.)

GALVANO'METER, or MULTIPLIER, is an instrument constructed for the purpose of detecting the presence of feeble electro-chemical currents. The nerves and muscles

of newly killed frogs were at first used; but the discovery of electro-magnetism has furnished a more delicate and measurable criterion: the instrument founded on this principle has been successively improved in the hands of Schweigger, Cumming, Nobili, and Melloni, to a most remarkable degree of delicacy.

The principle of the construction depends on the property possessed by electrical currents of acting on magnetised needles; for if the conducting wire be placed on the magnetic meridian above or below the needle, the latter will suffer a deviation to the right or left according to the direction of the current.

The action of terrestrial magnetism tending to restore the needle, after its derangement by the current, to its original position, is almost entirely corrected by employing two similar needles supported parallel to each other by a light piece of straw or other substance, and placed with the poles of one in an inverse position to those of the other. This apparatus being suspended by a fine silk thread, is placed in a wooden box of the form of a parallelopiped of small width, round which the conducting wire is passed in a great number of coils, which are kept from communicating by being doubly wrapped in silk or other non-conducting substance; the number of coils in some such instruments has been more than 500, by which the effect produced on the needle by a single current is multiplied twice as many times, since the opposite sides of each coil double the action of either side; and the terrestrial polarity of the needle being counteracted in the manner above mentioned, this simple instrument acquires a very great sensibility.

Modifications of the above construction have been made by Person, Peltier, and others, and a moveable index has been attached, particularly when weak thermo-electric currents are to be examined. Four needles have been used by some instead of two, but the principle of the construction in all cases is the same as that which has been described.

On the construction of electroscopes and galvanometers, the reader may consult *Annales de Physique*, t. xvi., p. 91, by Bohnenberger; t. xxii., p. 358, by Oersted; t. xxxiii., p. 62, by Colladon; t. xxxviii., p. 225, by Nobili; t. xlviii., p. 113, by Nobili and Melloni. Also *Biblioth. Univ.*, t. xxxviii., p. 79, by Nobili; *Phil. Trans.* 1823, by Pepys; also *Annals of Philosophy*, 1824, &c.

GALWAY, a maritime county of the province of Connaught, in Ireland; bounded on the north by the county of Mayo; on the north-east by the county of Roscommon, from which it is separated for the most part by the river Suck; on the east by parts of the counties of Westmeath, King's County and Tipperary, from which it it separated by the river Shannon; on the south by the county of Clare, and on the west by the Atlantic Ocean. It extends from 52° 57′ to 53° 42′ N. lat., and from 7° 53′ to 10° 15′ W. long., being about 164 English miles in length from east to west, and 52 in breadth from north to south. The extent of coast, which is very irregular, has been estimated at 400 miles; and the Shannon and Suck, both navigable rivers, nearly surround the rest of the county. The area, according to the Ordnance Survey, consists of—cultivated land, 955,713 acres; unprofitable bog and mountain, 476,957 acres; water, 77,922 acres; or 2360 statute square miles. The population, exclusively of the county of the town of Galway, was, in 1831, 381,564.

Physical Character, Rivers, Coast, &c.—With the exception of a spur of the Slieve Boughta mountains, running from the Clare boundary on the south-east towards Loughrea, and a similar extension of the Burrin range [CLARE] on the south-west of the same district, the whole of that part of Galway which lies east of Loch Corrib, being nearly of the same extent with the county of Tipperary, is comparatively flat, and although to a great extent encumbered with bog, is pretty generally improved and productive. A low table-land running north and south separates this part of Galway into two nearly equal districts, the waters of one of which run eastward into the Suck and Shannon, and those of the other westward into the head of Galway Bay and Loch Corrib. The district of the Suck is most encumbered with bogs; nevertheless it contains much well-improved land, particularly in the neighbourhood of Ahascragh and Ballinasloe. The district bordering on the Shannon also contains a large portion of bog on that side next the river, but has a good share of cultivation and improvement towards the interior. The district extending eastward from the head of Galway Bay is the richest part of the county. The country east of Loch Corrib is more diversified with hill and dale, and is generally in a good state of improvement. The centre of this eastern district of Galway is a bare flat tract, not equal in fertility to any of the other portions.

The whole district west of Lochs Corrib and Mask is known by the general name of Connamara, and has latterly attracted much attention by its capabilities of improvement, as well as by the uncommon wildness and beauty of its scenery. The bay of Galway bounds it on the south, the Atlantic on the west, and a deep inlet of the sea, called the Killery harbour, separates it on the north from the mountainous district of Murrick, in Mayo. From the head of Loch Corrib on the east to Achris Head on the west, this district extends 40 English miles; and from the head of Killery harbour on the north, to the shore of the bay of Galway on the south, 30 miles. The most prominent object is a group of conical mountains called the Twelve Pins, (probably Bins, synonymous with the Scotch Ben), of Bunnabola, rising abruptly from a table-land of moderate elevation which stretches south and west from their bases to the sea, and forms the chief habitable portion of the district. Round their bases are numerous lakes, of which the chief are Loch Ina, under the eastern front of the group; the upper and lower lakes of Ballinahinch skirting them on the south, and Lochs Kylemore and Foe lying between their northern declivities and the opposite range, which rises along the southern shore of the Killery. The average height of these mountains is about 2000 feet; some rise to 2400 feet, and as the table-land from which they rise is only of moderate elevation, their appearance is very striking. Northward and eastward from the Twelve Pins a range of equal altitude, but not of so picturesque a character, covers an area of about 200 square miles, between the head of Killery harbour and the western shore of Loch Mask. About midway between these waters lies the lake of Loughnascoy, north of which, to the boundary of Mayo, the country is entirely uninhabited. The chief elevations of this group, on the west, are Shanafola, at the head of Loch Corrib; Ben Leva, the declivities of which form the isthmus between Lochs Corrib and Mask; and the range of Maam Trasna overhanging the western shore of the latter lake. On the north the range of Furmnamore extends along the Mayo boundary, and on the west and south Maam Turk and Mameam rise over Loch Ina opposite to the eastern part of the group of Bennabola. Although this entire tract of country is generally known by the name of Connamara, it is properly divided into three districts: the portion last described, between the head of the Killery and Loch Corrib, being termed Joyce Country; that lying south of the Pins and range of Shanafola and Mameam being Iar-Connaught, or Western Connaught; and the remainder, extending westward from the Pins to the Atlantic, constituting Connamara Proper. The islands off the coast of Galway are very numerous; the chief are the three south islands of Arran, lying about midway between the coasts of Iar-Connaught and Clare, in the opening of the bay of Galway, and the islands of Innisturk, Innisboffin, and Innishark, extending, in like manner, across the offing of Killery harbour, between the coasts of Connamara and Murrisk.

On the southern side of the bay of Galway the coast is not favourable for the construction of harbours. From Burrinquay, in the county of Clare, to Kinvarra, at the head of the bay, there is no place of shelter for craft except at Killaney in Arran, and Durus on the mainland, opposite the town of Galway. The creeks of Ballynacourty and Rhenville are good harbours for vessels of a small class at the head of the bay, and the harbour of Galway has lately been much improved. Westward however from Galway, and round the entire coast of Iar-Connaught and Connamara to the boundary of Mayo, there is a succession of harbours for vessels of the largest class, unequalled perhaps on any similar extent of coast in Europe. The first of these noble roadsteads next Galway is Costello bay, at the mouth of the celebrated fishing stream the Costello, where a small pier was erected in 1822 for the accommodation of fishing-boats and merchant vessels. This harbour admits large ships, and is defended by a martello tower. Casheen bay, Greatman's bay, and Kilkerran bay occur immediately west from the Costello, being separated from one another by narrow peninsulas. The last-mentioned bay contains one hundred miles of shore, and is capable of receiving the largest vessels. A pier, five hundred feet in length, with a return of one hundred, was constructed

here in 1822; but as there is no road of any kind to the shore, it has been of comparatively little service. An extensive peninsula (ten miles by seven), interspersed with lakes, but destitute of roads of any kind, separates Kilkerran bay from the bay of Birterbuy, which runs inland about five miles, being only half a mile wide at the entrance, and from two to three miles wide within; it has deep water and fine ground, and might be easily fortified, so as to form a most desirable station for ships of war. On the western side of the entrance to Birterbuy bay is the opening of Roundstone harbour, a safe and capacious inlet, with clean good ground, and two to five fathoms' water. Roundstone harbour has been much spoken of as the terminus of a western Irish railway. At the head of the harbour, where the waters of the lakes of Ballinahinch and Loch Ina discharge themselves, is an excellent salmon fishery. A considerable village has sprung up within the last ten years at Roundstone, and as a road runs hither from the main line of communication between Galway and Clifden, there is a prospect of it becoming a place of some trade, especially as it is the nearest point for the shipment of the fine green marble of Ballinahinch. From Birterbuy the coast stretches, with occasional anchorages, to Slyne Head, the most western point of Galway; off Slyne Head lie a number of islands with navigable sounds between them, which remained unnoticed in the maps till Mr. Nimmo's coast survey, made for the late Commissioners of Irish fisheries: had the existence of these sounds been known, it is believed that many shipwrecks might have been prevented. Between Slyne Head and Achris Head occur the bays of Mannin and Ardbear, or Clifden; the former possessing one good anchorage, but exposed, and the latter an excellent harbour with safe anchorage in six to eight fathoms' water. At the head of this harbour a considerable town has grown up since 1822, at which time it consisted only of one slated house and a few thatched cabins. The commencement of a pier here by the proprietor, Mr. D'Arcy, assisted by Government in 1821, seems to have been the first step towards raising the place above the wilds which still surround it. So successful have the efforts of the proprietor been, that Clifden, in 1826, contained about one hundred good houses, roofed with Bangor slates, and about thirty country shops, the sales of which were estimated to contribute upwards of 3000*l*. per annum in direct taxes to the Government; and the consumption of taxable commodities is now stated to have increased to double the amount. In 1821 the population was 290; in 1831 it was 1257.

There is now a regular market in Clifden for corn, where, ten years ago, all the corn required was brought in barrels from Galway. A brewery, distillery, and milling concerns contribute principally to the demand; but there is also a regular export of corn and butter to Liverpool. As early as 1825 there were seven cargoes imported direct into Clifden for the use of the country; and there is now a regular import from America. North of Clifden harbour is Cleggan, an excellent roadstead, with a pier built in 1822, to which a branch of the new coast-road has been extended. Between Cleggan bay and the point of Renvyle, which forms the southern boundary of the entrance to the Killeries, is the harbour of Ballynakill, well sheltered by the island of Truchelaum, and capable of receiving vessels of the largest class. Rounding the point of Renvyle there is an open bay, from the head of which two inlets run eastward between steep mountains. These are the Great and Little Killeries; the latter an arm of the sea, about twelve miles in length, by a quarter to three-quarters of a mile in width, having, for a great part of its length, ten to twelve fathoms of water and clean ground. An island at the mouth completely protects it from the sea, but from being overhung on each side by steep and lofty mountains it is exposed to squalls, and not safe for sailing boats. The scenery of the Great Killery is much admired, and considered to approach nearest to the Norwegian *fiords* of any in these islands. On the whole there is no part of this district more than four miles from existing means of navigation. The harbours fit for vessels of any burthen are upwards of twenty in number; it contains twenty-five navigable lakes of a mile or more in length, and hundreds of smaller size. Loch Corrib and Loch Mask alone have upwards of seventy miles of navigable coast; and all these waters abound with fish. The sea-shore affords a constant supply of red and black seaweed, which can be used either as manure, or in the manufacture of kelp, of which latter article upwards of fifteen thousand pounds' worth has been manufactured in one season. Banks of calcareous sand and beds of limestone are of frequent occurrence, and there is an inexhaustible supply of peat fuel and of water-power. Yet, notwithstanding these capabilities, if the neighbourhoods of Clifden and Roundstone be excepted, the population still continues poor and thinly scattered along the coast, leaving the interior almost wholly waste. The population of this district is at present under 65,000, and the entire rental about 50,000*l*. per annum; although it is estimated to contain 350,000 Irish, or 615,000 English acres.

The rivers of Galway, being either feeders of the Suck and Shannon, or descending by short courses from the western district to the sea, are in general small. The river of Clare-Galway, which rises near Dunmore, in the north-east of the county, and passes near Tuam, has a course, from its source to its termination in Loch Corrib, of about 50 English miles. South of Tuam it expands into a periodical lake or turlogh: the waters generally rise in September or October, and do not subside until May, after which a coarse grass springs up, which is generally grazed as a common by the tenants of the adjoining land. Similar turloghs mark the surface of the country throughout the entire district bordering on the county of Clare; a phenomenon which is probably owing to the porous nature of the limestone rock which forms the substratum, which, being saturated with the autumnal rains, ceases during the winter to absorb the surface waters. Here, as elsewhere, on the verge of the great limestone tract which extends throughout the central district of Ireland, it is frequently perforated by subterranean cavities, which occasion the disappearance of numerous streams, and in some instances absorb considerable rivers. Thus, the river of Shruel, on the northern border of this part of the county, dips underground near Moycastle, and emerges before it terminates in Loch Corrib. The entire waters of Loch Mask also pass more than two miles by subterraneous channels under the isthmus of Cong into Loch Corrib. A considerable stream, which rises near Loughrea, after a south-western course of ten miles, during which it dips underground for half a mile, disappears in a turlogh about five miles from Gort; and two other streams in the more immediate neighbourhood of Gort sink and emerge frequently, and finally disappear without any visible outlet. The lakes of Loughrea and Gort are fine sheets of water; the latter has well-wooded banks and a very picturesque vicinity.

An extension of the Grand Canal connects Ballinasloe with the line to Dublin at Shannon Harbour. It has been proposed to carry on this line by Tuam to Galway, and to extend a branch from it to Loughrea. It has also been proposed to open a water communication northwards from Galway through the heart of Connaught by joining Lochs Corrib and Mask with the navigable lakes of Mayo. [CONNAUGHT.]

Prior to 1813, the only roads west of Galway were a narrow coast-road to Costello bay and a central road by Oughterard to Ballinahinch. These were led over rocks and bogs in so unskilful a manner as to be scarcely passable for any sort of carriage, and the only other means of communication through the district were narrow bridle-roads scarcely passable for horsemen in summer, and quite impracticable in winter. On the coast, in particular, there was nothing beyond the Costello better than a footpath. By the improvements begun in 1822 and still in progress under the Government, a complete line of carriage round the whole district has been effected. A coast-road has been formed which touches the heads of all the chief inlets from Costello bay to the Killery, where it joins an inland line leading through the heart of Joyce Country to the head of Loch Corrib, and thence across the central plain of Iar Connaught to the southern coast-road at Costello bay. These works and the expenditure of public money on piers and fishing harbours on the coast, have considerably promoted the general prosperity of the country; and the favourable statements of the various scientific men engaged in them have attracted so much attention to Connamara that there is a probability of its ultimately becoming the scene of extended mercantile and agricultural speculations.

Climate.—The climate is mild, and snow rarely lies in the western district. Cattle in this part of the county are never housed. The summers are wet, and the coast is exposed to very heavy storms from the Atlantic. According to the population returns for 1821, there were living in the

county of Galway at that time 21 females and 11 males severally over 100 years of age.

Geological Character.—The eastern district of Galway has not been geologically described, but, with the exception of a portion of the sandstone and clay-slate formation of the Slieve Boughta range, which it includes, and of the range of the Slieve Dert hills on the borders of Roscommon, it is understood to consist almost wholly of the same flœtz limestone tract which extends over the central plain of Ireland. The formation of the primitive district west of Lochs Corrib and Mask is better known. From Galway westward the whole coast to Slyne Head is a sheet of syenite, covered for the most part with a thin coating of bog, and containing many shallow lakes. This granite field forms a table-land of an average elevation of about 100 feet, and extends northward to the longitudinal valley which skirts the southern bases of the Twelve Pins, where it is succeeded by gneiss and mica slate, with beds of hornblende and granular limestone running east and west from Loch Corrib to Clifden. The group of Bennabola consists of a schistose quartz of a greyish brown colour, large sheets of which are exposed on the precipitous sides of all the chief eminences. On their northern bases the limestone, which shows along their southern side, disappears; and the mica slate and hornblende rise beyond Kylemore and the passes of Maam Turk into the southern mountains of Joyce Country: these are succeeded, more northward, by a transition tract of greenstone and grauwacke slate, covered by old red sandstone and conglomerate, constituting the entire country between the head of Killery harbour and Loch Mask, and extending beyond the bounds of Galway into the mountain-ranges of southern Mayo. To the westward of the Pins, the country, with the exception of the hill of Renvyle, which is a mass of quartz, consists principally of mica slate traversed by beds of granular limestone, and in some places by veins of granite. To the east the range of mountains rising from the northern edges of the granite tract terminate in the hill of Glen over Oughterard. All the formations of the district enter into the structure of this hill. On the west it is composed of quartz, and on the north of mica slate: granite and syenite constitute its eastern and southern faces, and the centre is penetrated by beds of hornblende and granular limestone with a capping of greenstone; which last rock also constitutes the mass of Ben Leva, and enters largely into the formation of the range of Maam Trasna. The line of demarcation between this primitive district and the flœtz limestone field of the eastern division of the county, pretty nearly coincides with the high road from Galway to Oughterard, north of which it enters the bed of Loch Mask, which it traverses and is again observable running northward and westward into the south of Mayo.

The mountains of the primitive district are highly metalliferous. The neighbourhood of Oughterard is rich in copper and lead; and abundant indications of the same ores have been found throughout the group of Bennabola. Fine green marble is quarried at Ballinahinch at the southern base of the same mountains, and the black and variegated marbles of Anglihan and Merlin Park near the town of Galway are of a superior quality. In the eastern district ironstone has been found at Woodford, Gort, and Lawrencetown: the works at the first place were carried on extensively at one time; but the supply of wood for smelting having been exhausted, they have been long since given up. Manganese is of frequent occurrence in the district about Gort, particularly in the neighbouring mountain of Slieve-an-oir (or 'the Gold Mountain') on the Clare boundary. Potters' clay and yellow ochre occur in the country about Athenry. A fine grit, fit for millstones, is raised near Dunmore; and the Slieva Boughta mountains above Loughrea afford an excellent stone for polishing marbles.

Agriculture.—The richest soil in this county occurs in a tract extending from Gort through Loughrea to Portumna, Eyre Court, and Ballinasloe. The wheat produced in the southern portion of this tract is of a superior quality; and the numerous demesnes lands occurring throughout it are among the most fattening pastures in Ireland. The remainder of the eastern district is more an oat and barley country, the best of which extends northward from Tuam to Dunmore and Shruel. On the lighter soils great numbers of sheep are fed, principally for the supply of the Leinster graziers, who purchase them for fattening, at the fairs of Ballinasloe. Throughout this district marl is of frequent occurrence. The only tract of cultivated ground of any considerable extent west of Galway is that which extends along the verge of the limestone plain to Oughterard. The improvements about Clifden, Ballinahinch, and Renvyle extend but a short way into the surrounding waste. Throughout the entire county of Galway, with the exception of demesnes, the dry-stone wall is the prevailing fence.

Large quantities of bog have from time to time been reclaimed. Experiments are now in progress on the bog of Critt, part of the estate of Lord Clonbrook, by which it appears that an outlay of about 14*l*. per acre is sufficient for the complete reclaiming of ordinary bog-lands in Galway.

Some resident proprietors have adopted the system of green crops, and conduct their farming on the Scotch and English plan; but these are very rare exceptions. An estimate of the amount and distribution of agricultural produce may be formed from the following table of the sales of grain for the year 1835 at each of the under-named towns. In order to afford an estimate of the increase or decrease of such sales in each, the total amount so sold within the ten years preceding is added:—

	For year 1835.			Total for 10 years preceding 1835.

Total for County	17,148	4,228	32,875	203,704	41,281	271,098

The produce in live-stock of Galway cannot be so accurately estimated, as Ballinasloe, the great fair for cattle within this county, is frequented by sellers from all the western parts of Ireland. At the October fair here, as many as 20,000 head of black cattle and 90,000 sheep have been sold within the week: the average value of cattle annually brought to sale has been estimated at 400,000*l*.

Fisheries.—The fisheries of the coast yield a very considerable produce. About sixty-three thousand long thousands (or eighty-five millions) of herrings appear to have been disposed of to country dealers and resident curers in Galway in the year 1836; which, at 10*s*. the long thousand, would yield the fishermen alone 31,500*l*. In the same year the total number of fishermen employed on the Galway coast was 8539, manning 1 decked vessel, 116 half-decked ditto, 479 open sail-boats, and 1376 row-boats. Besides the herring fishery, there is an excellent take of cod, ling, whiting, and turbot, from December to March; and of gurnet, mackerel, bream, and pollock, from May to August, together with a copious supply of oysters, lobsters, and crabs. The sun-fish deep-sea fishery peculiar to this coast deserves special mention. The sun-fish or basking-shark has its name from only appearing about sunrise and sunset, at which times it is distinguishable by its tail and back-fins protruding from the water. It is killed with the harpoon like a whale; and as the average bulk is thirty feet in length, and six tons in weight, it requires five or six men for three hours or more to kill a single fish. The oil yielded by the liver of an average-sized sun-fish is worth about 50*l*. To carry on this fishery with advantage, the boats should be decked vessels of from 40 to 80 tons, well-found, and capable of remaining at sea in all ordinary weathers; but, as there are none such in use among the fishermen of the coast, the pursuit of this profitable branch of industry has almost entirely ceased.*

* The manufacture of Kelp was formerly another source of considerable profit to the inhabitants of the shores: but owing to the decline in the price of barilla, it is not now so much attended to; and the use of the seaweed as manure is likely to prove more generally beneficial. The manufacture of coarse woollen hosiery also brings a return of about 10,000*l*. per annum into Connamara; and coarse linens and friezes are made to a large extent for home consumption.

The general condition of the people of Galway is somewhat better than that of the inhabitants of most other parts of Connaught, which probably arises from the residence of so many of the landed proprietors on their estates: 6*d.* to 8*d.* per day for 120 days in the year is the average rate of agricultural wages and employment. The manners of the people west of lochs Corrib and Mask are very primitive; and some of the clans still inhabiting the mountainous tract north of Oughterard and the Twelve Pins are remarkable for great stature and personal strength. The Irish language is very generally spoken.

Political Divisions.—Galway is divided into seventeen baronies, of which three are situated west of lochs Corrib and Mask: viz., Ross, nearly co-extensive with the district of Joyce Country, which contains but two small villages; Ballinahinch, nearly co-extensive with the district of Connamara, containing the town of Clifden (population, in 1831, 1257), and Moycullen, corresponding with the district of Iar-Connaught, which contains the village of Oughterard, with a population of 527. East of lochs Corrib and Mask the district bordering on Mayo is occupied by the baronies of Clare, containing the town of Headforth (population 1441), and part of the town of Tuam (total population 6883) [TUAM]; Dunmore, containing the town of Dunmore (population 847), and part of Tuam; and Tyaquin, containing no hamlet with more than 60 inhabitants: the district bordering on Roscommon is occupied by the baronies of Ballymoe and Killian, containing only hamlets; Kilconnell, containing the towns of Ahascragh (population 851) and Aughrim (population 587); and Clonmacnoon, containing part of the town of Ballinasloe, total population 4615: the district bordering on the Shannon has the baronies of Longford, containing the towns of Eyre Court (population 1789) and Portumna (population 1122); and Leitrim, containing only the village of Leitrim, of 280 inhabitants: the district extending from the centre of the county to the head of Galway bay and to the Clare boundary has the baronies of Athenry, containing the town of Athenry (population 1309); Loughrea, containing the town of Loughrea (population 6289); Dunkellin, containing the town of Oranmore (population 673); and Kiltartan, containing the towns of Gort (population 3627) and Kinvarra (population 824); the islands of Arran constitute a barony and parish in themselves.

Galway county is represented in the Imperial Parliament by four members, viz. two for the county, and two for the county of the town of Galway. The county constituency in 1836 was 3057.

Civil History.—The Anglo-Norman family of De Burgho and their followers, in the beginning of the thirteenth century, fixed themselves chiefly about Athenry and Galway, and maintained the administration of English law until the middle of the next century, when the assassination of William earl of Ulster [BELFAST] led to a revolt of the entire Connaught branch of the De Burgho family. The De Burghos of Galway, having assumed the Irish name of Mac William Eighter, to distinguish them from the Mac Williams Oughter, another branch of the same family, fell into the lawless practices of the neighbouring clans, and remained in all respects like native Irish till the reign of Elizabeth. English law was again introduced by the reduction of this county to shire-ground by Sir Henry Sidney in 1585; but the Irish mode of life continued to prevail until after the rebellion of 1641, and the war of the revolution of 1688, both of which events affected the property and population of this county to a great extent. The present proprietary are for the greater part of English descent; but the great mass of the population are the descendants of old Irish. The family of Joyce, which still forms the chief population of the barony of Ross, and are quite Irish both in language and manners, are said to be descendants of English adventurers, who settled here in the reign of Edward I.

Galway is very rich in antiquities. There are round towers at Ballygaddy, Kilbannon, Kilmacduagh Meelick, Murrough, and Ardrahan. Cromlechs and stone circles are of frequent occurrence. The antiquities of the episcopal seats of Tuam, Clonfert, and Kilmacduagh are contained within this county. Of the numerous remains of religious houses throughout Galway, the ruined abbey of Knockmoy is the most interesting. It was founded in the year 1189 by Cathal O'Connor, surnamed Crove-dearg, or 'of the red hand,' in consequence of a victory obtained by him over the English under Almeric St. Laurence. Above the tomb of the founder are some fresco paintings of great interest, as exhibiting the costume of the antient Irish: the Phrygian cap represented as worn by some of the figures will attract the attention of the antiquary. Abbey Knockmoy is also interesting for its architecture, which indicates a considerable advancement in the arts among its founders. The raths or earthern fortresses of the old Irish, and castles of the early Anglo-Norman lords, are also very numerous.

For the present state of education in this district see TUAM.

The county expenses are defrayed by grand jury assessment. The amount so levied in the year 1835 was 43,938*l.* 8*s.* 7*d.*

The constabulary force employed in Galway in the year 1835 consisted of 12 chief constables, 122 constables, 540 sub-constables, and 15 horse police, the total expense of which force was 23,553*l.* 19*s.* 8*d.* In 1835 the police force for this county consisted of one stipendiary magistrate, 13 chief constables, 135 constables, 582 sub-constables, and 19 horse; the total expense of this establishment was 26,565*l.* 6*s.* 9*d.*, of which 12,480*l.* 16*s.* 6*d.* was defrayed by the county.

The district lunatic asylum for Galway and the other counties is at Ballinasloe: it was opened in 1833, and accomodates 150 patients. (*Statistical Survey of the County of Galway*, Dublin, 1824; *Reports of Commissioners of Irish Bogs*; *Reports of Commissioners of Irish Fisheries*; Inglis's *Ireland*; *Letters from the Irish Highlands*, &c.)

GALWAY, County of the Town of, was erected into a separate county by charter of 8th James I. With the exception of the site of the county gaol and court-house, the county of the town embraces a tract of 23,000 acres, and includes the parish of St. Nicholas, and parts of the parishes of Rahoon and Oranmore. This district is divided into nearly equal parts by the river, which here discharges the waters of Loch Corrib into the sea. The town of Galway is built on both sides of, and on two islands in, this river; the main town is situated wholly on the eastern side. Galway is 102 Irish or 130 English miles from Dublin.

There does not appear to have been any trace of a town here till the year 1124, when a fortress was erected on this site, probably by the O'Flaherties, dynasts of Iar Connaught, which was destroyed by Conor, king of Munster, in 1132; and, having been rebuilt, was a second time demolished by Furlough O'Brien, his successor, in 1149. On the invasion of the English in 1180, Galway was again put in a state of defence by the O'Flaherties, from whom Richard De Burgho took it in 1232; and in 1270 the walling and fortification of the town were undertaken by the con-

querors. About this time the ancestors of many of the present leading families of Galway settled here, and from the entry of customs on the Pipe roll, it appears that the place at this time had already become a considerable depôt of foreign merchandize.

The power of the new settlers being confirmed by their victory at Athenry over the Irish, who had risen in aid of Edward Bruce on his invasion in 1315, the town, notwithstanding some interruption caused by the defection of the De Burghos in 1333, continued to prosper; and various subsequent grants of murage attest the importance which was attached to its preservation by the English government.

Although involved in frequent disputes with Limerick, arising out of the rivalry of trade, Galway continued to increase in mercantile prosperity till the middle of the seventeenth century. On the breaking out of the rebellion in 1641, the Earl of Clanricarde, after some opposition, occupied the town for the king. The concourse of persons taking refuge here from the troubles which succeeded produced a plague, which, between July and April, 1649, carried off 3700 of the inhabitants. On the final success of the Parliamentarians in 1652, Galway, after enduring a blockade of some months, submitted to Sir Charles Coote. On the breaking out of the war of the revolution in 1688, the inhabitants declared for James II., and continued attached to his cause until the defeat of the Irish at Aughrim enabled General Ginckle to come before the town with a force of 1400 men, to whom the place surrendered on honourable terms on 26th July, 1691. From this period down to the present time Galway has continued distinguished for its attachment to the established government, which was markedly evinced by the loyal services of the inhabitants during the rebellion of 1798.

The walls, which formerly contained an area of about twenty-two acres, have been almost entirely pulled down since 1779, and the town has now extended on all sides to a considerable distance beyond its former limits. Some of the antique residences still remain, which are generally square castellated buildings, with an interior court-yard and arched gateway opening on the street, in the Spanish taste. The whole of the old part of Galway, indeed, partakes of the appearance of a Spanish town, the result most probably of the extensive trade and intercourse maintained between it and the coast of Spain. The house of James Lynch Fitzstephen, who was mayor in 1493, and whose determined execution of the law upon his own son has given much interest to his memory, still stands in Lombard-street, commonly called 'dead man's lane,' in allusion to the event above referred to. The west bridge, built about 1442, connects the town with Ballymana island and the opposite suburbs.

The corporation of Galway consists of a mayor, two sheriffs, free burgesses unlimited, recorder, and town-clerk. The corporate authorities have exclusive criminal jurisdiction within the town, and a civil jurisdiction to any amount for debts contracted within the same limits. The borough quarter-sessions are held four times a year, and petty sessions two days in each week. The earliest charter extant is of 19th Richard II.; but this and other subsequent charters were reformed by the new rules of 25th Charles II., and by the present governing charter of 29th of the same reign. [CORPORATIONS OF IRELAND, p. 49.] The revenue of the corporation arises wholly from the tolls of the town, which in the year 1836 were let for 1260*l.* per annum.

This corporation has the patronage of a singular ecclesiastical body called the Royal College of Galway, which originated in a desire of the inhabitants to free themselves from the diocesan jurisdiction of the Irish archbishops of Tuam. This was carried into effect by a release executed in 1484 by Donat O'Murray, the then archbishop, which was subsequently confirmed by Pope Innocent VIII., and ratified by charter of 5th Edward IV.; erecting the church of St. Nicholas into a collegiate body, consisting of a warden and eight vicars choral, whose presentation and election lie wholly with the corporation. By the 15th section of 11 Geo. IV., c. 7, this privilege is now confined to the Protestant members of that body. The wardenship of Galway extends over the parishes of St. Nicholas, Rahoon, Oranmore, Clare-Galway, Moycullen, Kilcommon, Ballynacourty, and Shruel, and contains a total population of 68,145. Galway is represented in the Imperial Parliament by two members. The constituency in 1836 was 2064.

The port and harbour are under the control of commissioners acting under 1 and 2 William IV., c. 54. The harbour dues are at present let for 1260*l.* per annum; and on security of this revenue the commissioners have borrowed from the Board of Public Works a sum of 17,000*l.* for various improvements on the harbour now in progress. The mayor of Galway is *ex officio* admiral of the coasts of Galway bay as far as the isles of Arran.

The borough gaol erected in 1810 is situated on the upper of the three islands which the river here forms; and adjoining it is the county gaol, connected by a bridge, built in 1831, with the county court-house, a handsome cut stone building erected in 1815, with a portico of four Doric columns. The gaol is built on the semicircular model, and is kept in an excellent state of discipline. The borough court-house or Tholsel, erected during the civil wars of 1641, is a respectable edifice: the under part forms an extensive piazza.

Opposite the Tholsel, in the middle of the only plot of ground within the limits of the old walls, stands the collegiate and parish church of St. Nicholas, founded in 1320, by much the most imposing building in this county, if the lately-erected Roman Catholic cathedral of Tuam be excepted. It is of a cruciform shape, and extends in length 152 feet by 126 feet in breadth, including the side aisles; the height to the vault-nave is 42 feet 10 inches. From the intersection of the circles rises the tower, to which the steeple was added in 1633. In the interior are various monuments of interest still retaining many traces of sumptuous embellishment. The style of the building is the pointed Gothic. A sum of 1385*l.* has been recently granted by the Ecclesiastical Commissioners for its repair. The disposition of the streets within the circuit of the antient walls is very irregular; but in the newly-built portion of the town, particularly in the direction of the county court-house, uniformity and airiness have been more consulted. The custom-house, built in 1807, is a plain building. There are two barracks with accommodation for about 500 men.

This portion of the town is built on a gently-rising eminence stretching down to the river on the west, and to the sea on the south: on the latter side a creek of the bay forms a natural harbour, which is the site of the docks now in progress. These docks will occupy about nine acres, with water for vessels of 500 tons. The spit of land which separates this basin from the river is quayed for a distance of 1300 feet, and terminates in a return pier. There are also two small docks on the river side of the town, which constituted the quays for merchant vessels during the old period of its continental trade. A small open space adjoining is still called Spanish Parade.

On the western side of the river is the extensive suburb of Claddagh, which was a very filthy village until 1803, when Captain Hurdis, of the navy, at that time stationed on the coast, persuaded the fishermen by whom it is exclusively occupied to set apart a portion of their earnings for the paving and cleansing of their streets; and the Claddagh is now in this respect superior to many parts of the town itself. The inhabitants will not permit strangers to reside among them. The laws of their fishery and most of their internal regulations are under the control of a functionary whom they call their mayor, and elect annually. They all speak the Irish language, and the women still retain more of the Irish costume than is observed in any equally accessible district. In 1820 the number of their open sailing-boats was stated to be 250. In 1836 they are stated at 105, employing 500 men, with 80 row-boats employing 320 men. The entire population of this suburb, which is on the increase, is estimated at about 6000.

Although by the act of 2 Geo. II., c. 13, s. 19, the corporation are specially empowered to levy a tax for the lighting of the town, as well as the inhabitants generally by 9 Geo. IV., c. 82, neither of these acts has yet been put in force. Gas-works are however at present in progress of erection. The paving of the streets has been greatly neglected; and at night they have hitherto been left unprotected by any police. The fuel chiefly used is turf, which is brought in large quantities from the neighbouring coasts of Iar-Connaught and Connamara. The average price of coal is about 20*s.* per ton; but this is an article, the price of which fluctuates with the weather, and sometimes rises to a guinea and a half per ton.

The chief manufacture of Galway is flour, which, owing to a fall of fourteen feet in the waters of Loch Corrib, between that lake and the sea, has been carried to a very considerable extent. In 1820 there were twenty-three flour-mills, six oat-mills, two malt-mills, and three fulling-mills, driven by this water-power. The quantity of wheat ground and dressed at this time was estimated at 12,000 tons per annum, and the trade has since increased. There are a bleach mill and green on one of the islands, and an extensive paper-mill and several breweries and distilleries in the town.

The export of wheat, oats, and flour has, it is stated, trebled within the fifteen years preceding 1834. The exports from 1st September, 1833, to 5th July, 1834, consisted of 6018 tons of wheat, chiefly to Liverpool; 7212 tons of oats, chiefly to London; 1554 tons of flour; 406 tons of barley; and 50 tons of oatmeal. Besides this there is an export of kelp, marble, wool, and provisions. The imports consist of timber, wine, coal, salt, hemp, tallow, and iron. The following table exhibits the progress of trade during the last ten years:—

Year ending 5th Jan.	Custom Receipts in Port of Galway.			Vessels Inwards.		Vessels Outwards.	
	£.	s.	d.	No.	Tonnage.	No.	Tonnage.
1824	13,951	8	2	73	6,856	127	11,932
1825	17,308	2	5	156	13,169	150	11,536
1826	23,324	9	5	157	12,866	156	13,297
1827	29,913	7	8	140	12,992	140	10,132
1828	35,784	10	0	132	12,451	133	11,346
1829	40,109	18	6	129	14,251	153	14,562
1830	48,564	6	4	148	13,830	150	12,861
1831	36,260	8	3	132	14,006	107	10,936
1832	35,183	1	4	110	9,991	136	13,297
1833	27,755	4	8	112	11,577	136	14,398

In 1835 the customs had increased to 31,133*l.* 2*s.* 5*d.*: the vessels inward numbered 135, of an aggregate burthen of 12,915 tons; vessels outward 145, with a tonnage of 15,531. In the same year the excise duties for this district amounted to 50,154*l.* 12*s.* 5*d.*

Table of Population.

Date.	How ascertained.	No. of Houses.	No. of Families.	Families chiefly employed in Agriculture.	Families chiefly employed in Trade, Manufactures, and Handicraft.	Families not included in preceding classes.	Males.	Females.	Total.
1813	. . . . . .	3,353	..	..	..	..	..	..	24,684
1821	Under Act 55 Geo. III. c. 120.	3,957	6,238	..	..	..	13,346	14,429	27,775
1831	Under Act 1 Wm. IV. c. 19.	4,606	6,258	2,642	1,307	2,309	15,487	17,633	33,120

The number of young persons receiving instruction in the wardenship of Galway in 1834 was 2827, of whom 1763 were males and 1064 females. The majority receive their instruction from the Roman Catholic religious orders, who are more numerous in Galway than in any other part of the British empire. There are monasteries of the Dominican, Franciscan, and Augustin orders for men, with an equal number of nunneries of the same orders, together with a Patrician monastery, in which is a school, in connection with the National Board of Education, of 799 boys; two convents for nuns of the Presentation order, in one of which there is a school, also in connexion with the same Board, for 529 girls; and a Magdalen asylum. Two of the other schools within the wardenship are in connexion with the National Board.

There are four newspapers published in Galway, to which 39,810 stamps were issued in the year 1835. There are two subscription news-rooms and a library; but in 1834 there was no regular bookseller's shop in the town.

The expenses of the county of the town are defrayed by grand jury assessments, which, for the year 1835, amounted to 5,701*l.* 8*s.* 3*d.* The constabulary force in the same year consisted of one chief constable and twenty men, the expense of maintaining which amounted to 854*l.* 19*s.* 5*d.*, of which 413*l.* 19*s.* 7*d.* was chargeable against the county of the town. (Hardiman's *History of Galway*, Dublin, 1820; *Statistical Survey of Galway;* Inglis's *Ireland in* 1834; *Parliamentary Returns, &c.*)

GAMA, VASCO DE, the first European navigator who found his way to India by doubling the Cape of Good Hope, was born at the small seaport town of Sines in Portugal. The date of his birth, and the circumstances of his early life, are not mentioned. It appears that he was in the household of Emanuel king of Portugal, and having devoted himself to navigation and discovery, was appointed to the command of an expedition which was to seek its way to the Indian Ocean by sailing round the southern extremity of Africa. The notion of this passage was by no means a new one, and when it was taken up by the Portuguese sovereign its practicability had been pretty well established. In 1487 Pedro de Covilham set out for India by way of the Mediterranean, the isthmus of Suez, and the Red Sea, and he was accompanied as far as Egypt by Alfonso de Payva, who then left him to go in search of 'Prester John,' a great Christian king, who, after being sought for in various countries, was now reported to be living in a high state of civilization in the eastern parts of Africa. [ABYSSINIA.] Before their departure from Portugal, Calsadilla bishop of Viseu gave these travellers a map of Africa, in which that continent was correctly described as being bounded on the south by a navigable sea. This map, or the materials for it, had probably been procured from the trading Moors of North Africa, to whom the Portuguese had long before been indebted for much information concerning that continent.

Payva added little to geographical knowledge; but Covilham crossed the Indian Ocean, visited Goa, Calicut, and other places on the coast of Hindostan, acquired an exalted notion of the trade and wealth of those parts, and on his return towards the Red Sea he obtained from Arabian mariners some information concerning the eastern coast of Africa as far as Sofala on the Mozambique Channel. Soon after his return he visited Abyssinia, where he was detained by the government for some thirty years. Shortly after arriving in that country he found means of forwarding letters to the king of Portugal, in which he stated that no doubt existed as to the possibility of sailing from Europe to India by doubling the southern point of Africa, and he added that that southern cape was well known to Arabian and Indian navigators. The reports of Covilham, and the well-known importance of the trade with India, greatly excited the Portugese, who moreover had long been pursuing discovery on the western coast of Africa; and in the course of this, the fifteenth century, they had gradually extended their researches from Cape Non, in lat. 28° 40′ N., to Cape Cross, or de Padrono, in lat. 22° S. At the end of December, 1487, Bartholomew Diaz had returned to Lisbon after discovering 300 leagues of coast, and correctly laying down the great Cape, which he doubled in a storm without knowing it, but which he had properly recognised on his return. [AFRICA.] Vasco de Gama sailed from Lisbon on the 8th of July, 1497, five years after the discovery of the New World by Columbus. The royal squadron which he commanded consisted only of three small vessels, with sixty men in all. The Cape of Good Hope seemed to merit the name which had been given it by Diaz—Cabo Tormentoso. Dreadful tempests were encountered before reaching it, the winds were contrary, and their fears and their sufferings caused a mutiny among the sailors, who tried to induce Gama to put back. But the firmness of the commander quieted the apprehensions of his men, and on the 19th November, with a stormy sea, he doubled the Cape and turned along the eastern shore. [AFRICA.] On reaching the African town of Melinda, which belonged to a commercial and civilized people, a branch of the great race of Moors or Arabian Mohammedans, he found several Christian merchants from India, and he also procured the valuable ser-

vices of Malemo Cana, a pilot from Guzerat. This man was a skilful navigator: he was not surprised at the sight of the Astrolabe, or at their method of taking the meridian altitude of the sun. He told them that both the instrument and its uses were familiar to the mariners of the Eastern seas. Under the guidance of this pilot Gama made the coast of Malabar in twenty-three days, and anchored before Calicut on the 20th of May, 1498, then a place of considerable manufactures and foreign trade, which was chiefly in the hands of Moors or Arabs. Gama opened communications with the zamarin or sovereign prince of Calicut, who, after some negotiation, agreed to receive him with the honours usually paid to an ambassador.

The sailors, who were well acquainted with the character of the Moors, feared that if their commander put himself in their power he would fall a victim to their treachery and jealousy. The officers also and his brother Paul strongly dissuaded him from landing. But Gama was resolved. Arming twelve of his bravest men, he went into his boat, strictly charging his officers, in case he should be murdered, to return immediately to Portugal and there announce to the king the discoveries made, and his fate. On landing he was received with great pomp and ceremony by the natives, who conducted him through the town to a house in the country, where on the following day the zamorin granted him an audience. At first his reception was very favourable, but the tone of the prince soon changed; a circumstance which the Portuguese attribute to the intrigues of the Moors and Arabs, who were jealous of the new comers. The ill-humour of the zamorin was not soothed by an unlucky omission. Gama had not brought any suitable presents, and the few paltry things he offered were rejected with contempt by the officer appointed to inspect them. Whatever may have been the designs of the zamorin against the Portuguese, Gama, it is said, at last succeeded in convincing him of the great advantages he might derive from a commercial and friendly intercourse with the Portuguese; and he certainly was allowed to get back to his ships in safety. As soon as he was on board he made sail, and after repairing his ships at the Angedive Isles, on the coast a little to the north of Calicut, he again stood across the Indian Ocean. He touched at Magadoxa, or Mukdeesha, on the eastern coast of Africa and nearer to the Straits of Bab-el-Mandeb than he had gone on his outer voyage. He next anchored at Melinda, and took on board an ambassador from the Mohammedan prince of that place. He arrived at Lisbon in September, 1499, having been absent about two years and two months. His sovereign received him with high honours, and conferred on him the sounding title of Admiral of the Indian, Persian, and Arabian seas. This voyage of Gama is a great epoch in commercial history: it showed the nations of the West the sea-road to the remote East; it diverted the trade of the East from the Persian Gulf, the Red Sea, Asia Minor, Egypt, and Italy, the routes in which it had run for 1400 years; and it led ultimately to the establishment in India of a vast empire of European merchants. The effect it had upon Italy was most disadvantageous, and though there were other causes at work, the decline of the great trading republics of Venice and Genoa may be traced to the discovery of the passage to India by the Cape of Good Hope. Soon after Gama's return Emanuel sent out a second fleet to India, under the command of Pedro Alvares de Cabral. The most remarkable incident of this voyage was the accidental discovery of Brazil. [BRAZIL, vol. v. p. 369.] From Brazil however the little fleet got to India, and Cabral established a factory at Calicut—the first humble settlement made by the Europeans in that part of the world. But Cabral had scarcely departed when all the Portuguese he left behind were massacred by the natives or Moors, or by both. The Portuguese government now resolved to employ force. Twenty ships were prepared and distributed into three squadrons; Gama set sail with the largest division, of ten ships—the others were to join him in the Indian seas. After doubling the Cape, he ran down the eastern coast of Africa, taking vengeance upon those towns which had been unfriendly to him during his former voyage. He settled a factory at Sofala, and another at Mozambique. On approaching the coast of India he captured a rich ship belonging to the Soldan of Egypt, and after removing what suited him he set fire to the vessel; all the crew were burned or drowned, or stabbed by the Portuguese. He then went to Cananore, and forced the prince of that country to enter into an alliance with him; on arriving at Calicut, the main object of his voyage, he seized all the ships in that port. Alarmed at his display of force—for Gama had been joined by some of the other ten ships—the zamorin condescended to treat; but the Portuguese admiral would listen to no propositions unless a full and sanguinary satisfaction were given for the murder of his countrymen in the factory. Gama waited three days, and then barbarously hanged at his yard-arms fifty Malabar sailors whom he had taken in the port. On the next day he cannonaded the town, and having destroyed the greater part of it, he left some of the ships to blockade the port, and sailed away with the rest to Cochin, the neighbouring state to Calicut. These neighbours being old enemies, it was easy for Gama to make a treaty with the sovereign of Cochin, whom he promised to assist in his wars with Calicut. It is not quite clear whether a war existed at the time, or whether Cochin was driven into one by the manœuvres of the Portuguese; and according to some accounts, Gama only renewed a treaty which had been made by Cabral two years earlier. It was Gama however who first established a factory in Cochin, at the end of 1502. In the following year, the Alburquerques obtained permission to build a fort on the same spot; the Portuguese then became masters of the port and the sea-coast, and Cochin was thus the cradle of their future power in India. Gama left the zamorin of Calicut with a war with Cochin on his hands; and five ships remained on the coast of Malabar to protect the settlement. The admiral arrived at Lisbon with thirteen of the ships in the month of December, 1503. The court created him Count of Videqueyra. Gama however was not re-appointed to the command in India, where the career of conquest was prosecuted by Alburquerque, Vasconcellos, and others. In 1524, eight years after the death of the great Alburquerque, Gama, who had been living quietly at home for nearly twenty years, was appointed viceroy of Portuguese India, being the first man that held that high title. He died in December, 1525, shortly after his arrival at Cochin. His body was buried at that place, and lay there till 1538, when, by order of John III., his remains were carried to Portugal.

Vasco de Gama was a brave and skilful man, but owing to several circumstances his fame has been raised somewhat above his real merits. The main cause of this is probably to be found in the great national poem of the immortal Camoens, of a portion of which Gama is the hero, the adventures of his first voyage to India being described with even more than the usual brilliancy and amplification of poetry. (Barros, *Decades;* Castanheda and Lafitau's *Hist. Conqu. Portug.;* Cooley's *Hist. Mar. Discov.;* Camoens.)

GAMBIA, a river in Western Africa, whose embouchure is situated betwen 13° and 14° N. lat. and near 16° W. long. The upper course of this river has not been visited by European travellers; but according to information obtained from natives its source seems to be on the northern declivity of the mountain region which occupies nearly the whole country between the Sahara and the coast of Guinea, near the place where the 11th northern parallel is cut by 9° W. long. More than one half of its course lies through the mountain region itself. Where it begins to emerge from the mountains and enters the hilly country, which separates them from the plain along the shores of the Ocean, it receives on the right a considerable branch, the Nerico, which comes down from Bondoo with a south-western course. Up to the confluence with this river the Gambia seems to run in a west-north-western direction, but soon afterwards it turns due west, and continues this course to its mouth. After this change in its direction, the Gambia has a small impediment in its navigation at Baraconda, near Madina, but though it is usually called a fall, it is only a rapid which does not totally impede the passage of canoes or small boats. Up to this fall, as it seems, the tide ascends. Small sailing-vessels may go up to this point, from which to its mouth the course of the river is well known; it mostly runs through a flat country, which however for some distance is enclosed by hills and rising grounds; these heights however sink lower and lower, and disappear entirely at Kayaye, about 120 miles from the mouth of the river. The remainder of its course is through an immense plain. The flat countries along its banks are annually inundated and distinguished by their vigorous vegetation.

The English have some establishments along this river. Formerly there was one at Pisania, about 160 miles from the mouth, but it was abandoned in consequence of the an-

noyance frequently experienced from the people of Bondoo and Woolli. The farthest English establishment, we believe, is now at Jonkakonda, a little more than 120 miles from the mouth of the river. Other settlements are at St. James's and Iellifry; but the principal establishment is at the mouth of the river, the town of Bathurst, whence the produce of the country is shipped for England. [BATHURST.] The whole course of the Gambia probably exceeds 500 miles. It is called by the natives Ba Heema. (Mungo Park; Gray's *Travels in Western Africa.*)

GAMBOGE. [CAMBOGE.]

GAMBO'GIA. [HEBRADENDRON.]

GAME-LAWS were the remnant of the antient forest-laws, under which the killing one of the king's deer was equally penal with murdering one of his subjects; or, as Sir W. Blackstone somewhat quaintly expresses it, 'from this root has sprung a bastard slip, known by the name of the game-law, now arrived to and wantoning in its highest vigor, both founded upon the same unreasonable notion of permanent property in wild creatures, and both productive of the same tyranny to the commons; but with this difference, that the forest-laws established only one mighty hunter throughout the land, the game-laws have raised a little Nimrod in every manor.'

These laws decided what birds and beasts should be deemed game, prohibited all persons not duly qualified by birth or estate from killing any of such prohibited creatures, or even from having them in their possession as articles of food, and inflicted severe punishments and penalties upon the offenders against their provisions.

During the operation of the game-laws the gaols were filled with offenders against them, and profligate habits were induced, violence was committed, and misery of the most dreadful description was caused by the temptations to violate these enactments. Yet the landed proprietors continued to support the obnoxious system, regardless of the evil it produced; jealousies were created among themselves, and the most notorious injustice was perpetrated before individual magistrates and the courts of quarter-sessions, who could hardly be expected to judge offenders against their own cherished privileges with impartiality; until at last the legislature was compelled to interfere, and by a statute passed in 1831, 1 and 2 William IV. c. 32, the old system was materially improved. The whole of the former provisions respecting qualification by estate or birth were removed, and any person obtaining a certificate is now enabled to kill game, either upon his own land or on the land of any other person with his permission.

The sale of game is under certain restrictions legalised; and being recognised as an article of legal traffic, the statute very properly provides some more summary means than those previously in force for protecting it from trespasses. Poaching in the night-time still remains punishable by imprisonment for the first two offences, and by imprisonment or transportation for the third.

For the purposes of this statute the word Game is declared to include hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards; and the periods during which the different species of game may not be killed is declared, such periods being the breeding and rearing seasons of the different species; and penalties are imposed upon persons laying poison for game, or destroying the eggs of any bird of game, or of any swan, wild duck, teal, or widgeon, or knowingly having possession thereof.

The penalty imposed by the above statute for killing game without a certificate in the day-time is 5*l.* for each offence; and trespassers, even if licensed to kill game, may be fined 2*l.* with costs, or if in greater number than five persons, 5*l.* each, and the game killed may be demanded and taken from them. The penalties were made recoverable in a summary way before two justices of the peace, and if the party trespassing refuses to give his name and address, he may be apprehended and taken before a justice of the peace by the person entitled to the game, or the person entitled to the land, or any person authorized by either of them.

Gamekeepers are persons authorized by lords of manors or reputed manors to kill game; but the authority does not extend beyond the limits of the manor, though a gamekeeper may be appointed for any number of manors; the restriction indeed is rarely, if ever, insisted upon. The object of all game-laws being the preservation of game, it seems sufficiently attained by the prohibition to kill game during the breeding and rearing seasons. All persons having an equal right, under certain restrictions, to kill game during the rest of the year, have in fact an interest in enforcing the observance of the laws.

Though not coming strictly under the usual meaning of the term game-laws, we may mention that the salmon-rivers are closed during a certain specified period of the year, being the spawning season; a regulation considered necessary to preserve the breed of fish, and also because at that season the flesh is not wholesome for food. (4 Bl. *Com.*; Deacon *on the Game-Laws.*)

GAMING, or GAMBLING, is an amusement, or we might properly call it a vice, which has always been common in all civilized countries and among all classes, but more particularly the rich and those who have no regular occupation. But a passion for gaming is not confined to the nations called civilized: wherever men have much leisure time and no pursuit which will occupy the mind and stimulate it to active exertion, the excitement of gaming, which is nothing more than the mixed pleasure and pain arising from the alternations of hope and fear, success and failure, is a necessity which all men feel, though in different degrees according to the difference of temperament. The Germans, says Tacitus, stake their own persons, and the loser will go into voluntary slavery, and suffer himself to be bound and sold, though stronger than his antagonist; and many savage nations at the present day are notoriously addicted to gambling. Gaming has been described by Cotton, an amusing author who wrote in the beginning of the last century, as 'an enchanting witchery gotten betwixt idleness and avarice.' Besides the pleasure derived from the excitement that attends games of chance, there is no doubt that the desire to enjoy without labour is one motive which operates on a gambler: but this motive operates more on those who are practised gamesters than on those who are beginning the practice; and instances are not wanting of men strongly addicted to gaming, who have yet been indifferent to money, and whose pleasure has consisted in setting their property on a die.

In France, and many other parts of the Continent, the government has not only allowed, but has derived a considerable revenue from games of chance. In Paris, the *exclusive* right of keeping public gaming-houses was, until the year 1838, let out to one company, who paid an annual sum of 6,000,000 francs (about 240,000*l.*) for the privilege. They kept six houses, namely, Frascati's, the Salons, and four in the Palais Royal. In a recent trial in Paris, it came out in the course of the evidence, that the *clear profit* for 1837, exclusive of the duty, had been 1,900,000 francs (76,000*l.*), of which three-fourths was paid to the city of Paris, leaving the lessee 19,000*l.* for his own share. The average number of players per day was stated at 3000, and about 1000 more refused admittance. The games played were chiefly Roulette and Rouge-et-Noir, of which the latter is the favourite. It is very seldom that large sums are staked at the former, as the chances against the player are considered immense by *professional* men, a class of gentlemen who are gamblers by profession. Rouge-et-Noir is played with four packs of cards, and the 'couleur' which is nearest 31 wins; the black being dealt for first, and then the red. All the houses were open from one o'clock in the afternoon till one or two after midnight; and latterly till five or six in the morning. The highest play, especially at Frascati's, was carried on between three and six in the afternoon. Ten or twelve thousand francs were constantly lost at a sitting, and once within these few years 100,000 francs, which constituted the 'Banque' of the day, was won by a French nobleman. The actual chance of the table or 'Banque' is considered to be 7½ per cent. above that of the player, supposing the game to be fairly played, as it no doubt was in Paris, under the old system; the cards being examined and stamped by the government, and there being an agent of the police always present and ready to detect any attempted fraud on the part of the company. But admitting the game to be fairly played, the coolness of the 'croupiers' or dealers, who had no interest at stake (the whole of the losses or gains being taken by the company), and the large capital of the latter, made it absolutely impossible for the player to win, in the long run; nay, it is clear that he must lose, and that in proportion to his stake, which probably is regulated by his means. This we have heard admitted by the most constant frequenters of these houses; and nevertheless, under the influence of those causes which first lead men to gaming,

confirmed by habit and example, they still continue to indulge their passion till they are reduced to beggary, which is often followed by suicide.

That a vice which causes so much wretchedness should not merely be permitted and the practice of it superintended by the government, but that it should contribute considerably to the public revenue, has been a subject of loud complaint in France; and at last the ministers, in compliance with the desire of the Chamber of Deputies, have determined to grant no more licences after the 1st of January, 1838.

But though the intention is good, we apprehend that the determination to grant no more licences will, instead of preventing or lessening gambling in Paris, considerably increase it; and with this most pernicious difference, that instead of being carried on fairly as it is now, every kind of fraud will be practised by the illicit gaming-house keepers, in order to reap as much profit as possible before they are detected by the police. The lofty and splendid saloons of Frascati's, with their liveried servants and well dressed croupiers, will only be exchanged for miserable dens in the most infamous and retired streets of Paris, peopled by a set of ruffians who may possibly add murder to their other crimes.* In this and in many other difficult questions, as to how far and in what manner a state should interfere with the acts of its citizens, many zealous advocates for change and reform do not perceive the great distinction between making an enactment or establishing some practice with reference to a certain end, and repealing the same enactment after it has been long in force. The reasons which would be good reasons for not making such enactment, may also, either in their whole extent or to some extent, be good reasons for not repealing such enactment when once in force, or not discontinuing such practice when once established.

In England, gaming was very early the subject of penal enactments, but as a proof how futile all legislative measures hitherto made have been, we need only mention, and we do so without fear of contradiction, that there are more of those infamous places of resort, appropriately denominated 'Hells,' in London, than in any other city in the world. The handsome gas lamp and the green or red baize door at the end of the passage (as well known a sign as the Golden Cross or Spread Eagle) are conspicuous objects in the vicinity of St. James's, and of St. George, Hanover-square.

It appears that the playing at cards, dice, &c., was not punishable at common law; and an action may be maintained at law for money won at play; for the contract is not void in itself, and the winner's venturing his money is a sufficient consideration to entitle him to the action.

But if a person be guilty of cheating, as by playing with false dice, cards, &c., he may be indicted for it at common law and punished by fine or imprisonment. (2 Bac. Abr. 620.) All common gaming-houses are nuisances in consideration of law. By the statute of 33 Hen. VIII., c. 9, 'no person shall for his gain, lucre, or living, keep any common house, alley, or place of bowling, coyting, cloyth, cayls, half-bowl, tennis, dicing-table, carding, or any unlawful game, then or thereafter to be used, on pain of forfeiting 40s. a day;' and the same statute enacts that *every* person haunting and using the said houses, and playing, shall forfeit 6s. 8d.

By 16 Car. II., c. 7, any person who wins any sum of money by fraud, cosenage, deceit, &c., shall forfeit treble the value won. And by 9 Anne, c. 14, any person who shall 'at any *one time or sitting*, by playing at cards, dice, or *other game whatsoever*, or by betting on the sides of such as do play,' *lose* to any one or more persons, in the whole the sum or value of 10*l*., and shall pay the same or any part thereof, may within three months sue for and recover the same in any court of record, and after three months any other person may sue for and recover the same and treble the value thereof, with costs of suit.

By the 10th and 11th William III., c. 17, lotteries were declared public nuisances, and by several subsequent acts they have been prohibited under various penalties.

It is enacted by the 13th Geo. II., c. 19, that no horse-race shall be run for any prize of less than 50*l*. in value; and it has been decided that any wager on a horse-race made illegal by this statute is illegal also. Wagers considered contrary to decency or public policy, as on the sex or on the life of an individual, are also illegal and cannot be recovered at law or in equity. It is curious that gambling in the palace where the sovereign is residing for the time being is excepted from the statute of Anne, c. 14.

By 5 Geo IV., c. 83, persons betting, &c. in any street or open and public place, are punishable summarily as rogues and vagabonds.

A recent act (5th and 6th Will. IV., c. 41), repealing several old statutes, has altered the law relating to securities given for gaming transactions. It is enacted that in case any person shall make, draw, or execute any note, bill, or mortgage for a gaming debt, and shall actually pay to any indorsee, holder, or assignee of such note, bill, or mortgage, the sum thereby secured or any part thereof, such money shall be deemed to be paid on account of the person to whom such note, bill, or mortgage was originally given (upon the illegal consideration), and shall be deemed to be a debt due from such last-mentioned person to the person who shall so have paid such money, and shall be recoverable by action at law in any court of record.

In most parts of Germany gaming is allowed; and the magnificent saloons set apart for roulette and rouge-et-noir at Baden, Wisbaden, and other German watering-places, are well known to English travellers on the Continent. The respective sovereigns of the states in which these fashionable gaming-places exist derive an immense revenue by letting the exclusive privilege of keeping gaming establishments; and we may frequently see the grand-duke or prince playing at the table of his lessee, and losing a considerable portion of what he receives for granting the privilege.

In Italy and Spain gambling is a very common vice, especially among the lower orders, and you scarcely can find a muleteer, porter, or shoe-black, who has not a pack of dirty cards in his pocket, which he pulls out whenever he has a moment's leisure; and should he not be lucky enough to find a partner who will risk his money against him, he will frequently give a boy a trifle to play with him.

In the United States of America, but more particularly in the southern States, the practice of gambling is very common, though restrained, as we believe, in all the States by legislative enactments.

GA'MMARUS, a genus of Amphipodous Crustaceans, the *crevettes* or *cherrettes* of the French.

Generic character.—*Antennæ* inserted in front of the head between the eyes, moderate, composed of three principal joints and a fourth which is setaceous, multiarticulate and terminal; the upper antennæ with a small, setaceous, multiarticulate appendage at the internal extremity of their third joint. The four anterior *feet* terminated by a large compressed hand provided with a strong hook or moveable finger, which applies itself upon the lower edge; the four next feet terminated by a single joint, or slightly curved nail; the six last longer, raised on the sides of the body, and with a delicate and straight terminal joint. There are long, bifid, very moveable filaments on each side under the tail, which is terminated by long, ciliated appendages, which are extended nearly in the direction of the body, and which constitute a sort of spring, by means of which the animal executes considerable leaps, or aids its swimming by a backward impulse on the water. *Body* oblong, very much compressed, arched, divided into thirteen segments (including the head); each segment furnished above with a crustaceous, delicate, semi-transparent, transverse lamina or blade, and the seven first also furnished with a lateral crustaceous piece which covers the base of the feet. (Desmarest.)

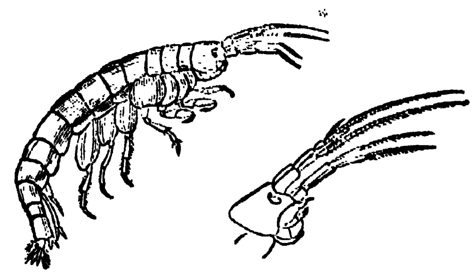
Example, *Gammarus Pulex* of Fabricius and Latreille; *Cancer Pulex* of Linnæus. *Squilla Pulex* of Degeer, *Squilla fluviatilis* of Merrett, *Gammarus aquaticus* of Leach, *Crevette des ruisseaux* of Geoffroy,—The *Fresh-water Shrimp*. This crustacean, which abounds in springs and rivulets, always swims near the bottom on its side, and its progression is principally performed by the rapid jerks of the appendages of the tail. The animal is carnivorous and feeds principally on dead fishes, and often on the carcasses of its own species. The male may often be seen swimming coupled with the female, which is much smaller, and which he holds between his legs. She keeps her eggs till they are hatched, and the young for some time seek shelter under her abdomen and the lateral appendages of her body.

There are some marine species; and Desmarest observes that the genus bears the strongest analogies to those genera which have been separated from it, in his opinion, on suffici-

* It is rumoured that Frascati's and the Salons are to be kept on, with the tacit approbation of the government.

ently slight grounds, under the names of *Leucothöe*, *Dexamine*, *Melita*, *Mœra*, *Pherusa*, *Amphithöe*, *Orchestia*, &c. The greater part of these, M. Desmarest states, have not been adopted by the more recent authors on the natural history of the Crustaceans, and the only ones which had been generally admitted when he wrote were *Talitrus* and *Corophium*. *Cerapus* of Say he considers to be founded on sufficient characters. M. Latreille however, in the fourth vol. of Cuvier's 'Règne Animal' (ed. 1829), admits them all.

Gammarus (Amphipoda) is noticed by Mr. Westwood as one of the types of each of the great groups of the typical Malacostracous Crustacea, which have been ascertained to undergo no change of form sufficiently marked to warrant the employment of the term metamorphosis. (*Phil. Trans.*, 1835.)



a, Gammarus Pulex, magnified; *b*, the head and antennæ of the same, highly magnified.

GAMMUT, in Music, signifies, in the popular sense of the word, the diatonic scale, as named either by the seven first letters of the alphabet, or by the syllables used in solmisation, *i.e.* do, re, mi, fa, sol, la, si. [DIATONIC SCALE.] And occasionally the term is applied to a single note—the G below the base clef. The word is compounded of the name of the third letter in the Greek alphabet, Γ (gamma), the final vowel being cut off, with the syllable *ut* added. In the eleventh century the antient scale was extended by the addition of a note below that sound which the Greeks called proslambanomenos (*i.e.* supernumerary), the latter answering to our A, the first space of the base staff, and the note was called *Gamm'-ut*,—that is, G *ut*, or G *do*.

The invention of the gammut in its antiquated form is generally ascribed to Guido d'Arezzo, but it now seems nearly certain that in part, if not wholly, it existed much earlier than his period. It long continued in use, and was one of the many stumbling-blocks in the path of musical students. Happily little more than the name remains; it is therefore unnecessary for us to enter further into the subject.

GANGA. [TETRAONIDÆ.]

GANGAM. [CIRCARS, NORTHERN.]

GANGANELLI. [CLEMENT XIV.]

GANGES. [HINDUSTAN.]

GANNAT. [ALLIER.]

GANNET. [BOOBY, vol. v.]

GANYME'DA (Zoology), Mr. Gray's name for a genus of radiated animals allied to the *Echinidæ* and the *Asteriidæ*, and which he thus characterizes.

Body hemispherical, depressed, thin, chalky, hollow. The back rounded, rather depressed, flattened behind, with a rather sunk quadrangular central space. The sides covered with sunken angular cavities, with a small round ring, having an oblong transverse subcentral hole in their base. Underside small, rather concave, with five slight sloping elevations from the angles of the mouth to the angles of the rather pentagonal margin. The edge simple. The mouth central. Vent none. Cavity simple. *Parietes* thin and minutely dotted: centre of the dorsal disc pellucid.

The genus, in Mr. Gray's opinion, is very nearly allied to Dr. Goldfuss's *Glenotremites paradoxus* (*Petrifact.* tab. 49, f. 9, and t. 51, f. 1), but Mr. Gray points out the differences, and is induced to consider these two genera as forming a family or order between the *Echinidæ* and the *Asteriidæ*; allied to the latter in having only a single opening to the digestive canal, and agreeing with the former in shape and consistence, but differing from it in not being composed of many plates.

Mr. Gray only knew of two specimens of *Ganymeda*, which he believes were found on the coast of Kent, as he discovered them mixed with a quantity of *Discopora Patina*, which he collected several years ago from fuci and shells on that coast. Size of specimens one-eighth of an inch in diameter. Species *Ganymeda pulchella*, Gray. (*Zool. Proc.* 1834.)

GAOL. [PRISON.]

GAOL DELIVERY. The commission of gaol delivery is directed to the justices of assize of each circuit, the serjeants and king's counsel attending that circuit, the clerk of the assize, and the judges associate. It is a patent in the nature of a letter from the king, constituting them his justices, and commanding them, four, three, or two of them, of which number there must be one at least of the judges and serjeants specified, and authorizing them to deliver his gaol at a particular town of the prisoners in it; it also informs them that the sheriff is commanded to bring the prisoners and their attachments before them at a day to be named by the commissioners themselves. Under this commission the judges may proceed upon any indictment of felony or trespass found before other justices against any person in the prison mentioned in their commission and not determined, in which respect their authority differs from that of justices of oyer and terminer, who can proceed only upon indictments found before themselves. (2 Hale, *P. C.*) [ASSIZE.]

Antiently it was the course to issue special writs of gaol delivery for each prisoner, but this being found inconvenient and oppressive, a general commission has long been established in their stead. (4 Bl. *Com.*; Hawk, *P. C.*)

GAP, a city in France, capital of the department of Hautes Alpes (High Alps), on the north-west bank of the little river Line, which flows into the Durance: 44° 34′ N. lat., 6° 5′ E. long. Gap is situated in the centre of a hollow: the neighbourhood is fertile, and the surrounding hills, naked and desolate in some parts, are in others entirely covered with vineyards. The streets of the town are narrow and ill-paved, and the houses poor: the public edifices are the cathedral, the episcopal palace, several Catholic churches and one Protestant church, the townhall, the prefect's office, the courts of justice, and the barracks. A public walk (boulevard) occupies the site of the town walls. The population of the town was, in 1831, 4572; that of the commune, 7215 in 1831, and 7854 in 1836. There are at Gap a commercial high school, a seminary for the priesthood, a museum of painting, sculpture, and antiquities, a museum of natural history, and a theatre. The diocese of Gap formerly included parts of Dauphiné and Provence: at present it consists of the department of Hautes Alpes.

Gap was in the middle ages subject to the counts of Forcalquier, and afterwards to its own bishops, who had the title first of princes, then only of counts. Its territory, which took from it the designation Gapençois, was one of the subdivisions of Haut or Upper Dauphiné. It was bounded on the north by Le Grésivaudan, on the south by Les Baronnies and by the dioceses of Sisteron and Digne, on the east by L'Embrunois, and on the west by Le Diois. [DAUPHINÉ.]

GAR-FISH, a species of fish inhabiting the European seas, and which is caught in tolerable abundance on various parts of the coast of our own country. This fish is allied to the Pike, and from the resemblance it bears to that species, has been called by some the *Sea Pike*. It is however of a more elongated form, and is remarkable for the great length and slenderness of the jaw-bones.

Both jaws are furnished along their edges with numerous small pointed teeth: the upper-jaw, which consists of the intermaxillary bones, is the shorter. The body is covered with scales, which are not very distinct. The dorsal and anal fins are of a simple form, and about equal in size: they are placed opposite each other, and not very distant from the tail, which is forked. The ventral fins are small, and situated behind the middle portion of the body. The upper parts of the head and back are of a deep blue-green colour, and the under parts are silvery-white: the dorsal fin and the tail are greenish-brown; the other fins are white. The ordinary length of this fish is about two feet.

The *gar-fish* is sold in the London and other markets; its flesh somewhat resembles that of the mackerel in flavour, but is more dry; before it is cooked it emits an unpleasant odour; the bones are green. 'The elongated narrow beak-like mandibles of this fish make a knowledge of its food a subject of some interest; but I have only found,' says Mr. Yarrell, 'a thick mucus in the stomach, without any remains that I could name. In all the works to which I have access I can find no mention of the nature of its food.'

In addition to the various parts of our coast, enumerated by Mr. Yarrell, in which the gar-fish is caught, the mouth of the river Mersey may be mentioned. From knowing that

the particular spot in which the fishermen find it in the greatest abundance is very plentifully supplied with sand-worms (*Arenicola piscatorum*), it has occurred to us that they might constitute its principal food. The beak-like jaws are well adapted to seizing such prey.

The gar-fish was included by the older writers in the genus Esox, and is the Esox Belone of Linnæus. It is now however classed in a separate genus, to which Cuvier applied the name of *Belone*, taking the old specific name for the genus, and giving that of *vulgaris* to the species above described.

GARCÃO, PEDRO ANTONIO CORREA, the best lyric poet of Portugal, was born at Lisbon in 1735. After labouring strenuously to correct the bad taste of his countrymen, his somewhat premature death at forty prevented the further success of his talents and exemplary perseverance. His attempt to supersede rhyme by quantity proved however a failure; not indeed from any lack of ingenuity on his part, but owing to the similarity and slight difference between long and short syllables, and the want of a dactylic copiousness which characterize modern languages, in even southern Europe. Garcao's odes, which are clothed in the diction of the sixteenth century, soar above the wearisome sameness of the sonnet and the eclogue of many a distinguished poet. His satires and epistles may be reckoned among the best in modern literature, and are decidedly more Horatian than Ferreira's. His simple drama in iambics, the 'Theatro Novo,' was evidently intended to counteract the passion for the operatic pomp of the Portuguese stage. The 'Assemblea, ou Partida,' another specimen of his plays, in the manner of Terence, is of the same kind as the 'Cecile' of Poinsinet, a satire on the fashionable world; not merely a picture of fashionable manners, as Bouterwek calls it. The 'Obras poeticas de P. A. C. Garcao,' in 8vo., were first published at Lisbon in 1778. (Bouterwek; and Sismondi, *Littérature du Midi de l'Europe*, or its translation by Roscoe.)

GARCILA'SO DE LA VEGA, the intimate friend and associate of Boscan in the radical and successful reformation of Spanish poetry, was born at Toledo, in 1500, or, according to some biographers, in 1503. His family enjoyed great consideration and military reputation; and Garcilaso himself, from the age of eighteen, followed Charles V. over Europe and in his expeditions to Africa till the disastrous retreat of the Imperialists from Marseille in 1536, when, being the first to mount the breach of a tower, which he was ordered to carry by assault, he lost his life in the attempt. He was perhaps the only individual who in that desolating and abortive campaign reaped any glory; at least he transmitted to posterity a more solid reputation acquired by his pen than the restless Charles gained by his policy and the sword. Nothing is recorded of Garcilaso but what is highly honourable to his character and talents, while Spain and Italy are still overwhelmed by the prolific mass of evils which the emperor inflicted on them by his misrule. Despising the clamour raised against introducing into a brave nation the effeminate taste (as his opponents called it) of the conquered Italians, Garcilaso, with equal boldness but greater skill than Boscan, substituted the modern Sapphic or Italian hendecasyllabic verse, both for the short metre of the antient romances and redondillas, and for the heroic Alexandrine and all the verses of *arte mayor*.

The sweetness of many of his thirty-seven sonnets captivates the ear, while the contrast of fear and desire, of sorrow and love, which they express, touches the sympathies of his readers. His odes are still more uniformly excellent; and his last is much praised by Muratori, as his 'Flor de Gnido' is by Paul Jovius and Sir William Jones. But his master-piece is the first of his three eclogues, which has never been equalled by any of the numerous imitations of it. Garcilaso wrote it at Naples under the inspiration of Virgil's tomb, and stimulated by Sanazzaro's reputation. It is to be regretted that in this piece, as in others, his facility and copiousness of expression betrayed him into diffuseness and over-refinement. Nevertheless he is at the head of the pastoral poets of Spain, and he would have been the first of her lyric poets, if he had lived longer, or if Herrera in the following century had not gained that title for himself.

Still Spain will always be indebted to a genius prematurely cut off for the earliest model of purity, elegance, and classical taste in her fine language. Even the severe Quintana, in his strict and lucid 'Essay on Spanish Poetry,' goes so far as to say that Garcilaso drew it suddenly forth from its infancy, and taught it closely to follow the footsteps of the antients and the most celebrated of modern writers; that he gave it wings and gracefulness; that while many words and phrases of his contemporaries have grown obsolete or have totally disappeared, his modes of expression can be used even at the present day. Garcilaso has been printed very often, and commented upon by Herrera, Sancho de las Brozas, Tamaio Vargas, and Azara, the elegant translator of Middleton's 'Life of Cicero,' and finally is now translated into English in a masterly manner by one of our eminent Spanish scholars, the late G. H. Wiffen, librarian to the duke of Bedford.

GARCILA'SO, the Inca, as he styled himself, was born at Cuzco, in Peru, towards the middle of the sixteenth century, after the conquest of that country by the Spaniards. His father Garcilaso de la Vega, allied by blood to the noble houses of Feria and Infantado, served under the Pizarros in that expedition. He married, at Cuzco, Elizabeth Palla of the race of the Incas, who is stated in her son's epitaph at Cordova to have been sister to Huayna Capac, the last emperor of Peru. [ATAHUALLPA.] Young Garcilaso came to Spain at an early age, about 1560; he obtained the rank of captain in the Spanish service, but he seems to have lived the greater part of his life at Cordova, where he died in April, 1616. His contemporary, Father Benaventura de Salinas, in his 'Memorial de la Historia del Nuevo Mundo,' chapter ii., says 'that he was much esteemed by the Catholic kings for the talents he displayed in writing his historical works; that he lived piously, and bequeathed by will his property, which was moderate, to the souls in Purgatory.' He was buried in the cathedral of Cordova, in a chapel which has been called, in consequence, 'Garcilaso's Chapel.' (See the Introduction to Garcilaso's *History of Florida*, Madrid, 1723.) Garcilaso wrote a history of Peru: 'Comentarios Reales que tratan del Origen de los Incas, de sus Leyes y Gobierno,' &c., fol., Lisbon, 1609. Garcilaso's history has been much praised for its impartiality, but its merits have been exaggerated from the supposition that the author, in consequence of his Peruvian connexions, had peculiar sources of information. This however seems not to have been the case. One advantage he had, that of understanding well his maternal language, and he says in his introduction that he was able to correct the misinterpretations of Peruvian words by Spanish writers. His style is reckoned inelegant and diffuse. He wrote an account of the conquest of Florida by Fernando de Soto: 'La Florida del Ynca, Lisbon, 1605. Both Garcilaso's 'History of the Incas' and his 'History of Florida' were translated and published in French, 2 vols. 4to., Amsterdam, 1727.

GARCI'NIA, a genus of the natural family of Guttiferæ, named in honour of Dr. Garcin who travelled in the East Indies. It formerly consisted of few species, but no less than 21 are enumerated by Dr. Wallich, 10 of which he considers new. These are distributed over the islands of the Indian Archipelago, in the southern parts of China, in the Indian and Malayan peninsulas, in Assam and Silhet, with one species (G. Cowa) extending as far north as Monghir on the Ganges. They are all trees of considerable size, with opposite coriaceous shining oval leaves; numerous flowers, which are monœcious or diœcious; in the male, stamens numerous, inserted on a large fleshy 4-lobed receptacle, anthers bursting longitudinally; in the female, stamens numerous but imperfect, ovary 4-10 celled, ovules solitary. The fruit fleshy and juicy, crowned with the peltate stigma, is edible in many of the species.

G. Mangostana is the most remarkable species, being the far-famed Mangosteen (*Mangees*, Marsden) of the Malays, reckoned one of the most delicious of all fruits, and not alone of the countries where it is indigenous, but, as Marsden says, 'is the pride of the Malay Islands and perhaps the most delicate fruit in the world.' It is a native of the Malayan Peninsula and of the Islands to the eastward of the Bay of Bengal, forming trees of considerable size, with a straight trunk and numerous spreading opposite branches forming an elegant conical head. The tree is considered one of the most ornamental in Batavia for gardens, also as affording an agreeable shade. Bontius compares their appearance to that of citron trees. It is in flower and fruit a great part of the year, according to Roxburgh, but Marsden says 'the returns of its seasons are very irregular.' So wedded is it to its indigenous soil and climate, that the innumerable attempts made to cultivate it elsewhere have uniformly

failed. Dr. Roxburgh says, 'For these 35 years past I have laboured in vain to make it grow and be fruitful on the continent of India. The plant has uniformly become sickly when removed to the north or west of the Bay of Bengal, and rarely rises beyond the height of two or three feet before it perishes.' The male and female flowers are sometimes on the same, but usually on separate trees. The germ is superior, round, from 6 to 8-celled, with one ovule in each, attached to the middle of the axis. The ripe berry is spherical, of the size of a pretty large apple, having the surface even, and crowned with the permanent peltate 6 to 8-lobed stigma. The rind is thick, firm, though somewhat spongy, of a dull crimson colour, sometimes compared to that of the pomegranate. Seeds as far as eight in number enclosed in a very abundant soft fleshy envelope which is delicately white, forming the edible part of the fruit, described as delicious to the taste and as dissolving away in the mouth. It is also extremely innocent in its nature, as almost any quantity of it may be eaten without detriment, and persons sick of almost any disease are allowed to partake freely of it without inconvenience. The fruit before ripening is slightly acid. The rind is powerfully astringent, and its decoction is employed in dysentery and as a gargle in aphthæ of the mouth. The bark of the trunk and branches is also considered astringent, and said to be employed by the Chinese in dyeing.

G. Cambogia, Cowa, lanceæfolia, Kydia, pedunculata, and paniculata, all yield a kind of edible fruit, but of these the last is most like the Mangosteen. From incisions made in the branches, a yellow juice exudes and soon concretes, having a close resemblance to, and in fact forming an inferior kind of gamboge; whence it has been inferred that this substance is yielded by a species of this genus, which has therefore been called G. Cambogia. Later investigations have proved the incorrectness of the opinion, and the true gamboge-tree of Ceylon has been determined to belong to a new genus named Hebradendron. [HEBRADENDRON.] G. Cambogia, Zeylona, Cowa, cornea, and pictoria (the last also supposed to be a species of Hebradendron), all yield an inferior kind of gamboge.

Garcinia Cambogia. The species supposed to yield Ceylon gamboge, and indicated as the gamboge-tree in many works. It is distinguished from the other species of Garcinia by its fruit being from 8 to 10-furrowed while that of others is simply round. It is called by the natives of Travancore *Gharka pulli*, and is therefore inferred to be *Carca pulli* of old writers. In Ceylon the fruit is called *Goraka*, and much used by the natives in their curries; when ripe it is said to form a fine fruit as large as the Mangosteen. The tree is one of the most common in the neighbourhood of Colombo, where it attains a large size and forms a handsome tree with thick dark foliage. Mrs. Col. Walker, in her letters to Dr. Graham, describes the outer husk of the fruit as being prepared by the natives by taking out the pulp and seeds, bruising and then heaping it up until the whole is soft. It is then smoked and kept within the influence of smoke, being much used as a favourite ingredient in their curries and also for preserving, along with salt, a small kind of fish, which thus cured will keep for six or seven months.

GARCZYN'SKI, STEPHEN, palatine of Poznania, died in 1755, at an advanced age. He spent all his life in public employments, which gave him the opportunity of acquiring a thorough knowledge of the affairs of his country. He published, in Polish, a political work on Poland, entitled 'The Anatomy of the Republic of Poland,' Warsaw, 1751, and Berlin, 1754.

GARCZYN'SKI, a young man of the same family, who died in 1832, in consequence of the fatigues of the Polish war of 1831, left behind him several poems, which are characterized by great beauties.

GARD, a department in the south of France, which derives its name from the river Gardon, which is found in some compounds (Vers du Gard, Pont du Gard), in the abbreviated form Gard. The department is bounded on the north by that of Ardèche; on the east and south-east by those of Vaucluse and Bouches du Rhône; on the south by the Mediterranean; on the south-west by the department of Hérault; on the west by that of Aveyron; and on the north-west by that of Lozère. The form of the department is irregular; its greatest length is in a direction nearly east and west about 76 miles; its greatest breadth, at right angles to the length, is about 70 miles. The area of the department is about 2294 English square miles, which is rather under the average of the French departments, and rather more than the combined areas of the three English counties of Cambridge, Huntingdon, and Northampton. The population, by the census of 1836, was 366,259, or nearly 160 to a square mile. In absolute and relative population it is below the average of the French departments, and also below the conjoint English counties with which we have compared it. Nîmes, its capital, is in 43° 51′ N. lat., and 4° 21′ E. long., and about 360 miles in a straight line south-by-west of Paris.

Surface: Hydrography; Communications.—The north-western part of the department is occupied by the branches of the Cévennes, of which the principal ridge is for the most part without the boundary of the department. From this part the face of the country gradually declines to the south-east, in which direction the principal rivers flow, to the lower part of the valley of the Rhône and to the Mediterranean. The coast and the lower banks of the Rhône are lined with étangs or pools of considerable size: those of Repausset and Escamandre are among the largest.

The principal rivers are—the Rhône, which bounds the department on the east; the Ardèche, which has the lower part of its course along the northern boundary; the Chassezac, a tributary of the Ardèche, which just touches the northern boundary in one part; the Cèze, about 55 miles long, and its feeders, the Luech, the Auzonet, the Aiguillon, and the Tave. The Gardon, which waters the central districts, falls into the Rhône, and is 65 to 70 miles long: its tributaries are all small. The Vidourle flows into the Etang of Manguio, in the adjacent department of Hérault. Its course may be estimated at from 48 to 50 miles. The Vistre, which flows near Nîmes, and the Rhosny, which flows near Aymargues, unite and serve as feeders to the canal of Radelle. The Hérault, and its tributaries, the Vis and the Rieulor, have their sources and part of their course in the department, as well as the Dourbie, an affluent of the Tarn. Of these rivers only the Rhône and the Ardèche are navigable.

There are several canals. That from the Rhône at Beaucaire to Aiguesmortes (undertaken A.D. 1776, finished A.D. 1812) is about 31 miles long; the canal of Silvéréal, which forms part of the navigation of one arm of the Rhône, is about 7 miles long; that of Bourgidou, from Aiguesmortes to the Canal de Silvéréal, about 6 miles; that of Grau du Roi, nearly 4 miles; and that of Radelle, little more than a mile: making together nearly 50 miles of canal navigation: in all about 111 miles of water communication.

The *Routes Royales*, or government roads, have an aggregate length of above 300 miles, but only about half, according to the official statements last published, are in repair. Of these roads the greater part converge at Nîmes. The *Routes Départementales* ('County Roads,' maintained at the cost of the department) amount to above 400 miles; but not two-fifths are in good repair: the bye-roads and paths (*Chemins vicinaux*) are estimated at 3000 miles. A railroad has been constructed (or is in course of construction) from Alais to Nîmes and Beaucaire: its length is about 43 miles. The above statements are taken from official sources.

Geological Character and Mineral Productions.—The department is chiefly occupied by the oolitic and other strata, which are found between the cretaceous group and the red marl, or new red (or saliferous) sandstone. The south-eastern portion is occupied by the rocks of the supercretaceous group. The primitive rocks which form the loftiest summits, and the western slope of the Cévennes, hardly appear in this department. Its mineral treasures are considerable; but they are either altogether neglected or imperfectly worked. There are mines of antimony, lead (which contains silver), sulphate of lead, oxide of iron, copper, calamine, and manganese, coal-pits, and quarries of gypsum. Ochre, asphaltum, sulphate of magnesia, and clay for porcelain and earthenware, of various degrees of fineness, are procured. There are extensive salt-marshes, the produce of which is considerable, and mineral springs in various places.

Climate.—The air in this department is commonly mild; but in March and April considerable changes of temperature are experienced within the twenty-four hours. In May the heat in the afternoon rises to 77° or even 86° (Fahrenheit); in June to 90° or 93°; and in July and August to 95° or 98°. The autumn is usually dry and cool. The greatest cold is commonly at the end of December.

Soil; Agricultural and other Produce.—The surface of the department is estimated to contain 592,108 hectares, or about 1,463,440 acres: the soil is thus classified:—Rich loam, 11,500 hectares; chalky or limestone, 125,000; gravelly, 15,500; stony, 325,000; sandy, 45,000; various, 70,108: total, 592,108 hectares. The sheltered hills and the plains are devoted to the cultivation of the vine, the olive, the mulberry, and the almond. The arable land is contained chiefly in the valleys. The produce of the department in grain is not sufficient for the home consumption; but what wheat is grown is of superior quality. The soil is thus appropriated:—Arable land, 157,535 hectares; meadows, 8,382; vineyards, 71,306; woods, 106,472; orchards and gardens, 1,592; osier and willow plots, &c., 2,162; various, 58,156; heaths, commons, and other wastes, 158,058; pools, ponds, and ditches, 2,766; lakes, rivers, brooks, 12,365; forests, and non-productive domains, 1,202; not accounted for, 12,112: total, 592,108 hectares. The quantity of arable land sown with different kinds of grain, &c., in 1835 was as follows:—Wheat, 28,953 hectares; rye, 6,286; maslin or mixed corn, 1,681; barley, 5,644; buckwheat, 2,081; maize and millet, 1,181; oats, 7,900; pease, beans, and other pulse, 891; other grain, 442; potatoes, 2,643. The great wealth of the department consists in its wines, and in oil, silk, and delicious fruits.

Only a small number of oxen are reared: but sheep are numerous, and their wool is very fine and much sought after. The horses are small, but vigorous, lively, and allowed to run almost wild. The wolf and the fox are common in the forests, but the wild boar is of rare occurrence: the beaver is occasionally seen in the islands of the Rhône, while the otter has his haunts on the banks of the Gard. Ortolans, red partridges, storks, and bustards are common; and the étangs and rivers abound with fish.

Divisions, Towns, and other Localities.—This department is made up of the former dioceses of Nîmes, and Uzès in Languedoc. It is now divided into four arrondissements as follows:—

Capital.	Population in 1831.	Population in 1836.	Situation, area, and population of arrondts.	sq. miles.	1831.	1836.
Nîmes,	41,266	43,036	S. & S.E.	650	128,461	131,712
Alais,	12,077	13,566	N. & N.W.	528	79,823	83,091
Uzès,	6,162	6,856	E. & N.E.	573	83,752	85,701
Le Vigan,	4,909	5,049	W	543	65,247	65,755
				2294	357,283	366,259

The whole department comprehends 38 cantons and 342 communes.

The towns in the arrondissement of Nîmes, beside the capital, and Beaucaire (population 9967) on the Rhône, of which an account is given elsewhere [Nîmes; Beaucaire], are: Aiguesmortes (pop. 2897), near the sea; Aramon (pop. 2417), on the Rhône; Montfrin (pop. 2331), on the Gard; Marguerittes (pop. 1925) and Milhaud (pop. 1613), on the Vistre; Sommières (pop. 3632), and Villevieille, adjacent to it, on the Vidourle; St. Gilles (pop. 5561), on the canal of Aiguesmortes and Beaucaire; Calvisson (pop. 2692), Aubais, Galargues (pop. 2096), Aymargues (pop. 2182), and St. Laurent, between the Rhosny and the Hérault, and Vauvert, between the Vistre and the Aiguesmortes canal.

Aiguesmortes is well laid out and well built: the houses are chiefly of stone, and of one story only, in order that they may be under the shelter of the ramparts. The inhabitants of the town are engaged in fishing and in procuring salt from the salt-marshes of Peccais, which are a short distance south-east from Aiguesmortes. From May to August 150 workmen are employed in them; but in the latter month more than 2000.

St. Gilles (distinguished as St. Gilles-les-Boucheries) is on an eminence; the kings of the Visigoths had a palace here, and it was the birthplace of Pope Clement IV. The environs produce excellent red wine.

In the arrondissement of Alais, beside the chief town, and Anduze (pop. 5020 town, 5554 commune) [Alais; Anduze], there are Barjac (pop. 1700 town, 1975 commune), between the boundary of the department and the river Cèze; St. Ambroix (pop. 2560 town, 2947 commune), on the Cèze; Genolhac, on a branch of the same river; and St. Jean du Gard (pop. 2788 town, 4128 commune), on the Gardon d'Anduze. At St. Ambroix silk, hats, leather, and nails are manufactured; and at St. Jean du Gard, silk and leather.

In the arrondissement of Uzès, beside the chief town, Uzès, there are Le Pont St. Esprit (pop. 4250 town, 4853 commune); Roquemaure (pop. 2653 town, 4138 commune), and Villeneuve les Avignon (pop. 3564), on the Rhône; Bagnols (pop. 3800 town, 4902 commune), on the Cèze; Laudun (pop. 1888 town, 2260 commune), on the Tave; St. Quentin, near Uzès (pop. 1770 town, 1994 commune); and St. Genies, near the south bank of the Gardon.

Le Pont St. Esprit (Bridge of the Holy Spirit) takes its present name (it was previously called St. Savournin) from a bridge, which at the commencement of the present century was the only one across the Rhône below Lyon, except the bridge of boats established for a part of the year between Beaucaire and Tarascon. Viewed from the river the bridge of St. Esprit presents, from its great length and height, the appearance of a wall built upon arches across the stream Its length is rather more than half a mile; its breadth not more than 14 or 15 feet between the parapets, so that carriages cannot pass each other, except in particular parts widened for the purpose. It has twenty-three arches, nineteen large and four small; beside which the piers have each a small arch above the starlings to admit the passage of the water in the time of the floods. This bridge was built with the offerings presented at a small oratory or chapel on the bank of the river, dedicated to the Holy Spirit; the first stone was laid A.D. 1265. Considering the state of the arts, the breadth and rapidity of the stream, it is a wonderful work. At Le Pont St. Esprit is a citadel built by Louis XIV. to bridle the Protestants of Languedoc. The inhabitants carry on a considerable trade by means of the Rhône, in oil, wine and silk. There is a considerable yearly fair.

The inhabitants of Roquemaure are engaged in silk-weaving and in distilling brandy. There is an old castle, once belonging to the counts of Toulouse. Villeneuve les Avignon forms a suburb of Avignon [Avignon], from which it is separated by the Rhône.

In this arrondissement, on the road from Lyon by Le Pont St. Esprit to Nîmes, is Le Pont du Gard. This aqueduct-bridge, designed to convey the waters of the fountain of Aure to Nîmes, crosses the valley and stream of the Gardon, uniting two steep hills by which the valley is bounded at this place. It consists of two tiers of large arches, and a third tier of small arches which supports the trunk of the aqueduct. The channel for the water is above four feet wide and five deep, and is lined with cement three inches thick, and covered with a fine coat of red clay. The bottom is formed with small stones, gravel, and chalk. The whole work is built of stones joined without mortar or any other cement, except in the trunk for the water. The river, over which the bridge is carried, does not in summer occupy more than one of the arches of the lowest tier; but in the floods in winter its stream is so swelled as to occupy them all.

In the arrondissement of Le Vigan are: Le Vigan, the chief town, on the Arre, a feeder of the Hérault: Valleraugue (pop. 1878 town, 3895 commune), on the Hérault; Sumène (pop. 2030 town, 3017 commune), on the Rieulor; St. André de Valborgne, on the Gardon d'Anduze; La Salle (pop. 1750 town, 2270 commune), on one of the affluents of the Gardon; Aulas, near Le Vigan; and St. Hypolite, or Hippolyte (pop. 5120 town, 5214 commune); Sauve (pop. 2851 town, 3021 commune); and Quissac, on the Vidourle. Le Vigan is amid the Cévennes. The inhabitants are engaged in the manufacture of silk and cotton stockings and leather. St. Hypolite is well built: it is traversed by a canal which supplies several fountains. The inhabitants are engaged in the manufacture of leather, woollen stuffs, and silk and cotton stockings.

The population of the towns, except when mentioned to be otherwise, is from the census of 1831.

In respect of education the department occupies a low place; but it is in advance of the adjacent departments, except that of Hérault. Of the young men enrolled in the military census in 1828-29, only 40 in 100 could read and write. The condition of the mountaineers who occupy the mountains which separate this department from that of Lozère, is very wretched. They dwell in huts built of stone, without windows, and almost without roofs; and a considerable part of their subsistence is derived from the chesnuts, which constitute the only produce of their soil. They are a stunted and ill made race.

This department constitutes the diocese of Nîmes, the bishop of which is a suffragan of the archbishop of Avig

tion. There are many Protestants in the department; they constitute a majority of the population, and have seventeen consistorial churches. The department is within the jurisdiction of the *Cour Royale* of Nîmes, and in the circuit of the *Académie Universitaire* of that city. Among the buildings not subject to taxation, the official returns enumerate 5 prisons, 4 schools, libraries, or establishments for superior education, 24 hospitals or almshouses, and 452 churches and chapels.

The department sends 5 members to the Chamber of Deputies. It is in the ninth military division, of which the head-quarters are at Montpellier.

GARD, PONT DU. [GARD.]

GARDA, THE LAKE OF, the antient Benacus, the largest of the Italian lakes, is in the Lombardo-Venetian kingdom, between the province of Brescia on the west and that of Verona on the east; the boundary between the two provinces crosses the lake in its length. Its south coast belongs to the province of Mantua. The northern extremity of the lake enters the territory of Trent in the Tyrol. Its length, which is north by east to south by west, is 28 Italian miles of 60 to one degree of latitude; and its greatest breadth, which is in its southern part, is 11½ Italian miles; but it is much narrower towards the north. Its greatest depth is about 1800 feet. (Quadri, *Prospetto Statistico delle provincie Venete.*) It receives at its northern extremity the river Sarca, which rises in the mountains of Tyrol, and numerous other streams on its east and west banks. The Mincio issues from its south-east extremity by the fortress of Peschiera. Two ridges of mountains run parallel to its east and west banks; that on the east is more rugged and nearer to the coast, but the western ridge leaves a fine and fertile strip of land between it and the bank, and is known by the name of Riviera di Salò. The south coast of the lake forms part of the great plain of Lombardy. Some account of the territory along the banks of this lake, the scenery of which has been praised by Catullus, Dante, and other poets, is given under the heads BRESCIA and VERONA, THE PROVINCES OF. There is a good description of the lake in Valery's *Voyages Littéraires en Italie.* A steamboat plies on the lake of Garda, between Desenzano on its south coast, and Riva at its north extremity, in the Tyrol. The lake has some small islands near its west coast, the largest of which is called 'Isola Lecchi,' from the name of the family to which it belongs, and is little more than one mile in circumference.

GARDEN. A garden, as distinguished from a farm, is a piece of ground designed for the cultivation of plants not actually indispensable to man for food. While corn for flour, various roots and herbs for the sustenance of cattle, or tracts of pasture land on which animals destined for slaughter are maintained, constitute the essential features of a farm; a garden, even when exclusively occupied by culinary vegetables, is still a source of objects of luxury, not of first necessity; in a more extended sense, and as it usually exists at the present day, it is chiefly intended to gratify the senses and to minister to the more refined enjoyments of social life.

The possession of a garden is one of the most early indications of civilization in man, and it is only among the most brutal and degraded races of savages that it is altogether unknown; while we find such an appendage to a dwelling increased in magnificence, or diminished and neglected, with the prosperity or decline of the most mighty states. It is Lord Bacon who says that 'when ages do grow to civility and elegancy men come to build stately sooner than to garden finely, as if gardening were the greater perfection.'

According to Sir John Malcolm, the Persians had gardens from the period of their first king Mahabad. We learn from Xenophon that Cyrus considered them an indispensable appendage of his residences. 'Wherever he resides, or whatever place he visits in his dominions, he takes care that the *paradises* shall be filled with all that is beautiful and useful which the soil can produce.' (*Cyropæd.* v.) And it appears upon the testimony of Pliny and other Roman authors, that among the same people small gardens existed, in which trees were arranged in straight lines and regular figures, the margins of the walks being planted with tufts of roses, violets, and other odoriferous flowering plants, while the trees consisted of kinds grateful for their fragrance, as the cypress and the pine, or agreeable for their shade, as the plane and the common elm. The Greeks, in their most flourishing times, appear to have been equally attached to the formation of gardens, and even, in some respects, to the nicer parts of the art of gardening. The Oriental narcissus, violet, ivy, and rose, are mentioned as their favourite flowers, and terebinthinous trees as those which were chiefly valued for their fragrance. The rich and polished Athenians are represented by Mr. Meason as having borrowed their gardening from Asia Minor. Myrtles and roses, the box and the lime-tree, were planted for clipping into artificial forms, while flowers and fruits were cultivated in the winter, and the violet was in profusion in the Athenian markets when snow was lying on the ground.

Theophrastus himself not only gives directions for gardening operations, many of which were fanciful enough, such as sowing rue with chips of fig-wood, and pulling up esculents by way of making them more tender, instead of cutting them; but he had a garden of his own which he left to ten of his friends to be preserved as a place of public resort for those who employed their leisure in letters and philosophy. (Diogen. Laert. v. 53.) The instances of the kings Attalus Philometor [ATTALUS] and Mithridates, who cultivated all sorts of poisonous plants in their gardens, are perhaps the earliest upon record of such places being occupied for medical purposes.

It is not to be supposed that gardens were neglected by the luxurious and wealthy Romans. The prodigious gardens of Lucullus, who introduced the cherry, the peach, and the apricot from the Persians, were derided by his Roman friends for their extraordinary sumptuosity. They are related to have consisted of immense artificial towers, large sheets of water, gigantic edifices jutting into the sea, and mountains raised where no hill had existed before. Such an example might be ridiculed by some, but was certain to be followed by others whose taste for splendour and profusion was supported by unbounded wealth; and accordingly the gardens of Sallust, of the emperors Nero and Hadrian, and of many of their subjects, are doubtless to be classed in the same order as those of Lucullus. It is however to be remembered that such gardens were rather more similar to an English park and garden combined than to a mere garden, in the modern sense of the word, and moreover were so uncommon as to be looked upon with wonder by the people among whom they were created. A common Roman garden must have been a very different place, if we are to take the description given by Virgil (*Georgic*, iv. 121) as at all a faithful sketch; for he speaks of nothing but endive (intyba), celery (apium), melons? (cucumis), narcissi, acanthus, roses, ivy, and myrtles. That they had various trees bearing fruit, as well as the common wild timber of the country, and many different kinds of flowers, must of course be admitted; but that all gardens, up to the most flourishing period of the Roman empire, must have been much alike in respect to the plants they contained, is manifest from the fact that hardly more than seventy plants of all descriptions are noticed by this poet, although he wrote professedly upon rural affairs. It is true that the Romans carried their passion for flowers so far that it became necessary to restrain it by sumptuary laws, and that cases of extreme profusion in the use of them are mentioned by historians. The institution of Floralia, or flower-feasts, the universal passion for garlands, the reproaches addressed by Cicero to Verres for having made the tour of Sicily in a litter, seated on roses and decked with festoons of flowers, are a sufficient evidence of this taste having been carried to an extent unknown at the present day; to say nothing of the prodigality of Heliogabalus, or of Cleopatra, the latter of whom is said by Athenæus to have paid upwards of 200*l.* (an Egyptian talent) for roses expended at one supper. But notwithstanding this, the variety of plants that were cultivated in the gardens of both Greeks and Romans must have been extremely small. Theophrastus speaks only of roses, gillyflowers, violets, narcissi, and iris, as used for decoration, to which the larkspur and gladiolus (hyacinthus), with the white lily, and a few others may be added. The great object of their admiration was roses, which were forced by plates of talc (said to have been as much as five feet long; but it is more probable that these *specularia* were sashes five feet long, glazed with talc) being placed over bushes watered with warm water. Pliny, in his 'Natural History,' does not enumerate above one thousand plants of all descriptions, a very small part of which were objects of cul-

tivation. At the fall of the Roman empire the following appear, from Mr. Loudon's statement, to have been the principal garden plants, exclusive of common trees and flowers. 1. *Culinary plants* —peas, beans, vetches, lentils, kidney-beans, gourds, cucumbers, melons, cabbages of many sorts, turnips, carrots, parsnips, beet, skirret, radishes, sorrel, asparagus, onion, garlic, and other alliaceous plants, endive, lettuce, succory, mustard, and other salads, parsley, celery, orach, alexanders, elecampane, fennel, chervil, and some others. 2. *Fruits*:—fig, almond, citron, peach, pomegranate, apricot, plums, and cherries; twenty-two sorts of apples, thirty-six sorts of pears, services, quinces, and medlars; many kind of grapes, mulberries, nuts, walnuts, chesnuts, stone-pines, or pignons, olives, and carobs. They forced flowers with sashes of talc, as has already been noticed, and also cucumbers; it is probable that they extended this practice even to fruits.

With the fall of the Roman empire the art of gardening seems to have been lost, and it was not till a long time after that gardens are again heard of. It was among the monks that the arts of cultivation were preserved, and in connection with monastic institutions gardens again became matter of history. In these religious institutions, which were in many respects the only spots where the arts of peace could find shelter during ages of rapine and violence, gardens continued to be cherished; and although the ignorance of the monks prevented their being rendered so useful as they might have been, yet, on the other hand, their sacred protection opposed an effectual barrier to the wild progress of destruction.

Among his many reformations, the re-establishment of gardens formed part of the policy of the emperor Charlemagne, who introduced the subject into his *capitularies*, commanding gardens to be formed throughout his dominions, and prescribing the very plants which were to be cultivated therein: and considering the state of learning in those days, it must be admitted that the list, short as it is, was prepared with good judgment; for it was made to contain the most useful plants then known for diet or medicine, as well as the favourite ornamental flowers of the Romans. The reader of the present day may be amused at the list of what was thought in the eighth century deserving of an imperial edict, at a time when no one had heard of a garden except within the walls of a castle or a monastery (*Walafridi Strabi Hortulus*):—Roses, Lilies, Fenugreek, Costmary (Costus), Sage, Rue, Southernwood, Melons, Gourds (Cucurbitæ), Water Melons (Pepones), Kidney Beans, Cummin, Rosemary, Caraway, Lentils, Squills (?), Gladiolus, Tarragon, Cucumbers (Coloquintida), Heliotrope, Ammi majus, Sium angustifolium, Lettuce, Nigella sativa, Rocket (Eruca), Nasturtium, Dock, Alexanders, Parsley, Celery, Savin, Fennel, Dittany, Woodmint, Water Mint, Catmint, Centaury, Beet, Marsh Mallows, Carrot, Orach (Adripia), Kohl Rabi, Chives, Radishes, Onions, Madder, Beans, Chervil, Clary, Lovage, Anise, Succory, Mustard, Savory, Mint, Tansy, Poppy, Asarabacca, Hollyhocks, Parsnip, Blite, Cabbage, Leeks, Rocambole, Garlic, Teasel, Peas, Euphorbia Lathyris (Lacteridæ), Houseleek. From this proceeding of Charlemagne the revival of gardens may be said to date, for although there are few direct traces of their existence for some centuries, yet there is no reason whatever to suppose that they were ever again lost sight of. In the fourteenth century we find Matthæus Sylvaticus, a Mantuan physician, speaking of his own garden, and of a Colocasia cultivated in his greenhouse on the edge of a beautiful fountain, and of a plant called Cantalis, supposed to be Athamanta cretensis, which he says he brought out of Greece and planted in his garden. (*Pandect.* c. 197, 133.) It was however in Italy that the formation of gardens received a fresh impulse. Alfonso d'Este, duke of Ferrara, is recorded to have founded several botanic gardens in the 16th century, and especially one called Belvedere surrounded by the water of the Po. The example was followed by several nobles of Ferrara; John Brasavolo, the uncle of the botanist Musa Brasavolo, had a viridarium or greenhouse; another noble, of the name of Acciajuoli, had many rare plants in his garden; and the collections of this city, augmented annually by the commerce of its merchants with Greece and Asia, became so rich in new exotic plants as to become celebrated all over Europe. The Ferrara gardens were soon rivalled by those of the Venetians and Paduans, one of whom, Gaspard de Gabrichis, is said to have spared no expense to enrich his garden, not with costly edifices and vast architectural embellishments, but with plants before unknown. (Spreng. *de R.H.* iv. c. 3.) The greatest and earliest garden however of this æra is generally considered to have been that founded at Pisa, in 1544, by Cosmo de' Medici, on the banks of the Arno; which by the year 1555 had become so rich in plants by the exertions of Lucas Ghini and his successor Cæsalpinus, as to have been the admiration of Belon, no mean judge. Haller indeed is of opinion that a greenhouse built by the bishop of Acquapendente dates from the year 1533, but this is at variance with the statement of Tiraboschi, who fixes the erection in the year 1545. Be this as it may, it is at least certain that about this period a public garden was formed at Bologna, others at Lucca, Naples, and Florence; and that at Verona one Cæsar Niclesola had two large greenhouses in which some very rare plants were preserved. (Pona, *It. Bald.* p. 9.)

At this time Paris possessed no garden for its university; that of Montpellier had however been founded by Henri IV., and contained before the end of the sixteenth century upwards of 1300 French, Alpine, and Pyrenean plants, according to Olivier de Serres (*Traité d'Agricult.*, 1600), and a famous garden had been created at Mans by Renate Bellaye, bishop of that city. In Germany too, the garden of Breslau, to which Tragus and Fuchs were attached, of Basle, Strasburg, and other places, were at this time in existence, and the since celebrated garden at Leyden had been founded in 1577, at the instance of Gerard Bontius.

The principal part of these establishments were founded for academical purposes; when they were formed for private gratification their owners must be considered very much in advance of their times, if we are to form an opinion from the state of private gardening in this country at the same period. Here the only purpose contemplated in the formation of a garden appears to have been an enclosed place in which the owner might walk in seclusion, or in which sport might be had with contrivances like mazes and labyrinths formed of close-cut hedges; a few fruit-trees were added; but no such object as that entertained by the refined Italians, of collecting rare and beautiful plants from foreign countries for pleasure or for scientific purposes, was thought of. In the gardens of Nonesuch, the palace of Henry VIII., executed about the year 1540, we hear of shady walks, columns and pyramids of marble, 'fountains that spout water one round the other like a pyramid, upon which are perched small birds that stream water out of their bills,' and of similar objects, but nothing of the more essential part of a garden—its plants. Pleasure-grounds of this description had existed in England from the time of the Conqueror. Upon this point Mr. Loudon has collected some curious information, but antiquaries have rarely attended to the subject, and a rich field of investigation certainly still remains open to whomsoever is disposed to enter upon it. It is stated by Fitzstephen that in the time of Henry II (1154—1189) the citizens of London had large and beautiful gardens to their villas. In the reign of Edward I. (1272—1307) it may be collected from 'Holinshed's Chronicle,' that the cultivation of the garden was extended to the more curious and delicate productions: but the wars of York and Lancaster destroyed all these occupations, and gardens in general ceased to be more than pleasure-grounds or kitchen-gardens of the rudest kind till the time of Elizabeth. King James I. of Scotland describes the garden at Windsor Castle, where he was confined by Henry V., as a place set thick with trees, and alleys of hawthorn hedges, with an arbour in each corner,—

> 'And myddis every herbore might be sene
> The scharp green swete jenepeie.'—*The Quair.*

Much later (1512) the great Earl of Northumberland, whose household consisted of 160 persons, 'had but one gardener, who attended hourly in the garden for setting of erbis and clipping of knottis, and sweeping the said garden clean.' Nay, it should seem as if sometimes there was not even one; for among the workmen of the household is mentioned the gardener of the place where my lord lyeth, *if there be one.* (Loudon.)

In these remarks all reference is omitted to the gardens of the Arabs; about which almost nothing is known, but which seem to have been more deserving historical record than those of other contemporary nations. That this people in the height of their power paid great attention to botany, is well known to those who are familiar with that science. A learned work on rural affairs was written in the 12th century by Abu Zachariah Ebn Alva, a native of Seville, of

which an epitome has been given by Casirius (*Bibl. Escurial*, i. 326, s.); and according to Mr. Loudon, this writer has left a list of plants cultivated in the garden of Seville, more extensive than that of the Greeks and Romans. In the 13th century the then Vizir of Cairo, Ebn-Beitar, a native of Malaga, was so much attached to botany that he visited all parts of the East for the express purpose of extending his knowledge of plants. His works are preserved in MSS. in the library of the Escurial, and it is said that although he scrupulously abstained from describing anything which he had not seen, yet he speaks of 2000 species more than Dioscorides. (Spreng. i. 238.) It is only reasonable to suppose that such a man had a garden. We must however fix the period when gardens first began to be extensively improved, in the middle of the 16th century, when, as has been already shown, the rich Italians turned their attention to the introduction of new and rare plants. By the time that this new taste began to be fixed in the minds of Europeans, the numerous geographical discoveries that had been made by the Portuguese and Spaniards, had opened new and unheard-of sources from which the lovers of gardens were able to enrich them. It would appear that the maize, the yam, tobacco, and the cotton-tree (Bombax) were brought to Europe by the Spaniards so early as the end of the 15th century (Barcia, *Hist.*, i. 24), and king Ferdinand is recorded to have preferred the pine-apple, brought home in Columbus's second voyage, to all other fruits. (Petr. Martyr. *Reb. Oc. Dec.* l. 2, b. 39.)

It would be impossible to trace the progress of public taste in the construction of gardens any farther historically, without occupying more space than such a subject can have allotted to it in a work of this description. It may easily be conceived that from the time when the taste for gardens revived, up to the present period, there has been a gradual improvement in such places, commensurate with the wealth of individuals and the commercial power of nations, their peaceful habits, the security of property, and their general progress in settling the relations of social life. At the present day the most prosperous nation is Great Britain, and here the cultivation of gardens is unrivalled as a general national object: the most degraded are Spain and Portugal, and there a feeling for garden enjoyment is almost extinct. In the remainder of this article we shall offer a few remarks upon the most important causes which have contributed to bring gardens to their present improved condition, and conclude by a brief account of some of the most remarkable Botanical Gardens of the present day.

The first great step that was made by gardeners to advance their art beyond mere mechanical operations, was the invention of glasshouses, in which plants might be grown in an artificial climate, and protected from the inclemency of weather. Until this was effected, it is obvious that the cultivation of exotic plants in Europe, especially its northern kingdoms, must have been much circumscribed. Mr. Loudon refers the invention of greenhouses to Solomon de Caus, architect and engineer to the Elector Palatine, and who constructed the gardens at Heidelberg in 1619. But there can be no doubt that buildings of this description claim a higher antiquity. The specularia of the Romans, whether pieces of talc 5 feet long, or, as we rather suppose, sashes 5 feet long glazed with talc, were certainly used for the purpose of forcing roses and some other plants; they were essentially greenhouses, although perhaps more like our garden-frames. It is scarcely likely that where gardening survived, the learned men, in whose hands all such subject then were, should have been unacquainted with the existence of these specularia, and they would naturally endeavour to reconstruct them. Greenhouses certainly existed among the Italians in the middle of the 16th century, as has been already mentioned, and there is no reason to suppose they had then for the first time been thought of. In fact, the antient viridarium seems to have been a room with one side of it glazed with sashes reaching from the top to the bottom, and resembling the old English conservatory. It may or may not have been heated; probably not, for it was chiefly Greek, Egyptian, and Levant plants that were at first cultivated as rarities by the wealthy Italians, and they required no artificial heat in Italy.

If heat was required, it would be supplied by stoves or such other contrivances as were used for domestic purposes. Ray says, that in 1684 the greenhouse in the Apothecaries' garden at Chelsea was heated by means of embers placed in a hole in the floor; and it appears, from a section of a greenhouse in the Electoral garden at Manheim, published in 'Medicus Index Plantarum,' that a German stove was used there as late as 1771. We however agree with Mr. Loudon in considering the invention of *glass-roofs* for greenhouses to be an æra from which the principal part of modern improvements takes its date. This happened in 1717, when Switzer published the plan of a forcing-house, suggested by the Duke of Rutland's graperies at Belvoir Castle. Up to that time the want of light must have rendered it impossible to employ greenhouses for the growth of plants, either in winter or summer; they could only have been hybernatories, receptacles in which plants might be protected from wet or cold during winter, but from which they were transferred to the open air as soon as the spring became sufficiently mild. The substitution of glass-roofs, by increasing the quantity of light, put it at once in the power of the gardener to cultivate permanently in his greenhouse those natives of hot countries which are not capable of bearing the open air of Europe even during the summer. From the time of Switzer to the present day there has been a gradual improvement in the construction of greenhouses, the object being to supply the plants with as nearly the same amount of light when under the glass-roof, as they would have had if in the open air. The modern invention of curvilinear iron-roofs has accomplished this end in a most remarkable degree: for they substitute an obstruction to light amounting to only $\frac{1}{23}$ or $\frac{1}{27}$ for a loss equivalent to $\frac{1}{4}$ or even $_{"}$

The mode of heating such houses has given the modern cultivator additional advantages of the greatest importance. Stoves of all kinds not only dry up the moisture of the atmosphere, but impregnate the air with gaseous exhalations unfavourable to vegetation. The substitution of flues, whil it equalized the heat, was still worse than the stove in drying and deteriorating the air; the introduction of fermenting vegetable matter, such as tan in a pit, in the interior of the house, remedied this evil in some measure, but the application of steam-pipes or hot-water pipes has had the great advantage of obviating every inconvenience, and has given the gardener the power of modifying the heat and moisture of his greenhouse at pleasure. Add to this, the rapidity of communication between one country and another, the long peace with which Europe has been blessed, and the leisure it has given men to occupy themselves with domestic enjoyments, the great encouragement given to gardeners, the establishment of Horticultural Societies for the promotion of the art of gardening, and the discoveries made in vegetable physiology—add all these things to the improvements in greenhouses, under which name is here included all descriptions of glass buildings for horticultural purposes, and there is no difficulty in accounting for the present flourishing condition of European gardens.

There is one point further that requires to be noticed, as contributing to this result, and that is, the extension of the education of the working gardener. Great numbers of gardeners are now well informed in the higher branches of their profession. Instead of trusting to certain empirical rules, or to *receipts* for gardening operations, as if growing a plant was much the same thing as making a pudding, they make themselves acquainted with the principles upon which their operations are conducted, they acquire a knowledge of botany and vegetable physiology, and some even of physical geography, and thus they place themselves in the only position from which they can securely advance to the improvement of their art. The necessity of these subjects forming a part of all gardeners' education cannot be too strongly insisted upon; the Horticultural Society of London have recognised their importance by requiring all the young men in their garden to pass an examination in such subjects, in addition to their possessing the usual gardeners' acquirements; and although people ignorant of such subjects themselves have been found absurd enough to blame the proceeding, there can be no doubt that the world will give the Society the credit they deserve for having been the first to set this most important example, which we trust will be followed by all such institutions through the country.

In noticing modern gardens we must necessarily confine ourselves to a few of the most remarkable, passing by entirely those of private individuals, and in general all second-rate public establishments. The reader who is desirous of procuring detailed information upon the subject will find an ample account of all the best modern gardens in Mr. Loudon's ex-

cellent *Encyclopedia of Gardening*, edition of 1835, to which we have been much indebted for this article.

Although the restoration of gardens took place among the nobles of Italy, and many noble instances of wealth and taste applied to such purposes still remain, yet the political condition of that country is unfavourable to horticultural pursuits, and although there are gardens attached to most of the Italian cities, there are none of much note, except for their picturesque features and fine architectural embellishments. Those of Naples, Florence, and Monza near Milan, are the most remarkable, especially the last. This is described as seated in a park of 3000 acres, with a gently varied fertile surface. It is well watered; 'the culinary, flower, botanic, and fruit gardens, orangeries and hothouses, are all good, and as well managed as the circumstances of the present vice-king will permit.' The river Lambro passes through the grounds. There is a double avenue leading to Milan planted with tulip-trees, magnolias, melias, robinias, and other flowering trees, interspersed with evergreens and American oaks, the whole having a very beautiful effect. Among other things there is in this garden a shrubbery composed entirely of Magnolia grandiflora, some specimens of which have attained a great height. The botanic garden contains a numerous collection of plants from all parts of the world. The hothouses are numerous, and shelter an immense number of orange and lemon trees, as well as other plants of ornament. Pine-apples are also grown with some success.

The Dutch, although too much attached to the stiff formal style of clipped hedges, straight walks, and architectural puerilities, have always had a great reputation as gardeners. Their wealth and their commerce with the Cape of Good Hope and the East Indies gave them for a while extraordinary advantages over other nations, and for a long time their garden of Leyden was considered the richest in Europe. It was begun in 1577; in 1633 it contained 1104 species, and was so rapidly enriched by the zeal of the wealthy Dutch merchants, that in 1720 no fewer than 6000 species were catalogued by Boerhaave, who was then professor of botany at Leyden. From this source was at one time obtained the principal part of the succulent and other plants native of the Cape of Good Hope. It was afterwards a good deal neglected, but is now renovated under the care of Dr. Blume. It was thus spoken of by the author of a 'Tour through South Holland,' who visited it in 1830:—'It does credit to all who belong to it, being kept in the highest possible order. Its walks are beautiful, and without a pebble; they are covered with a mixture of peat earth and the spent dust of tanners' oak bark. The garden is tastefully laid out in clumps of shrubbery in various forms, round which, on borders, are the various plants, named and numbered according to the system of Jussieu. The whole extent is seven acres; four of which have been added only a few years ago, and laid out in good taste by the late professor Brugmans, as a garden for the reception of medicinal plants, and for the use of the medical students. Among the hothouse plants we saw a date-palm with fruit upon it, which tree the gardener said had been there 200 years. It may be questioned whether the botanic garden at Leyden and its museum are not superior to the Jardin des Plantes and its museum in Paris. Taken altogether, we are of opinion that they had a decided preference, though they wanted the attraction of living animals.

In the Netherlands there are small public gardens, both at Antwerp and Ghent, and one of the finest in Europe at Brussels. Some years since it was a wretched place, scarcely deserving the name of a garden; but in 1826 it was removed to its present site on the boulevards, and entirely reformed. It now contains a range of hothouses, 400 feet long, ornamented with a rotunda and porticos, and an extensive collection of plants. The roof of the houses is formed of curvilinear iron bars, and the whole is heated by steam. The principal range is seated on a terrace, with several fountains and broad flights of steps in front of it; while on a lower level are two low ranges of pits for pineapple plants and small tropical species. Opposite to the hothouses are the herbaceous grounds, laid out in a circular manner, and divided into small compartments for the Linnæan classification. (Forbes's *Tour*.) The author from whom this statement is taken complains of the ground being occupied by common forest trees and shrubs, with but little novelty or rarity among them.

Among the German sovereigns a taste for gardening has grown up in a degree unknown in any other country except among the English. A love of the beautiful, a fondness for natural objects, a quiet contented character, so characteristic of the German nations, has no doubt been the cause of this. In Loudon's 'History of Gardening,' no fewer than ninety closely printed pages are occupied with short accounts of the principal gardens of Germany only. Of these we can only select those of Munich, Berlin, and Vienna.

The garden of Munich, under the direction of Dr. Von Martius, is extremely rich in plants that can be cultivated in greenhouses and hothouses, but poor in those species which require to be grown in the open air: this happens in consequence of the severity of the winter, which destroys even the holly. There is a very fine range of hothouses, containing numerous palms, succulent and other plants. It is however considered that the plants in the hothouses at Nymphenburg are much finer than those at Munich; the collection of palms contains larger specimens; but it excites the surprise of the English traveller to find Laurustinuses and Rhododendrons treated as greenhouse plants.

The botanic garden at Berlin has long been one of the great sources from which the gardens of Europe have derived supplies of new plants, chiefly from Brazil, Mexico, and the Cape of Good Hope, in which country the king of Prussia has maintained collectors. It contains many hothouses and greenhouses, each of which is often dedicated to the reception of plants of some one tribe only. There is one for Endogenous plants exclusively, another for ferns and palms, a third for New Holland plants, and others for heaths, Cape, New Holland, and Mexican plants; there are some very fine palms, and in all respects the collection of species is probably the most extensive in the world. Mr. Forbes, the gardener to the duke of Bedford, who visited it in 1837, speaks of it in terms of great admiration. He says he never before saw so many plants cultivated in pots. 'The numerous species of New Holland and Cape genera were quite astonishing, as well as the hardy and Alpine species.' In point of beauty however there is nothing in the garden of Berlin to be compared with the conservatory in the garden of Pfauen-inseln, one of the pleasure-gardens of the king of Prussia. This building is 120 feet long, 40 feet wide, and 42 feet high; it has a span roof, but the north side is of solid brick-work, having a gallery running along it, from which the visiter looks down upon the plants beneath. In this place are some noble palm-trees; Latania borbonica is 27 feet high, Pandanis utilis 23 feet high, a Dragon-tree 36 feet high, and many others of unusual magnificence. The Latania is placed in the middle of the conservatory, having the tub in which it grows concealed by ferns and various low-growing plants.

If the garden of Schönbrunn is less rich in plants than that of Berlin, it much excels it in the magnificence of its hothouses and greenhouses. The emperors of Austria have for above a century been anxious to render this garden the finest in the world; and no cost has been spared in sending gardeners to foreign countries in order to increase the collection. It is however chiefly by supplies from the tropical parts of America that this garden has been enriched. There are several ranges of glasshouses, one 270 feet long and 30 feet high, another 300 feet long and about the same height, and three lower ranges, each about 240 feet long. Nothing can exceed the beauty of the interior of some of these glass palaces, in which the species are grouped with great taste, and which from their size allow the plants to grow with all their native tropical luxuriance.

Rivalling these imperial structures are the gardens of St. Petersburg, founded by the emperor Alexander on the Apothecaries' Island in the Neva. In a country with such a climate as Russia gardening can hardly exist except under glass roofs, and it is necessary to call in aid all the resources of art in order to overcome the difficulties of nature. It is not surprising then that in this situation the glasshouses should exceed in extent those of all other parts of Europe. Altogether there are 3624 feet of such buildings, forming a double parallelogram, the principal sides of which are 700 feet long and from 20 to 30 feet wide. The middle range is 40 feet high in the centre. All this vast extent of glass is heated by common flues. In the open ground there is a large collection of hardy plants, a quarter devoted to systematical botany for the purposes of students, an arboretum, and a division for medicinal species. One excellent feature in the internal arrangements of this garden is the

placing the plants geographically, so that the most careless observer in proceeding through the different suites cannot fail to be struck with the changes in vegetation as he passes from Africa to America, to New Holland, to India, China, and so on.

In France gardening has never been in a very flourishing condition; it is true that great quantities of vegetables are raised for the market, that the fruits of France are justly celebrated for their excellence, and the flower-markets of Paris are well supplied; it is also true that numerous excellent works on gardening have been written in France. But for the quality of their fruit the French are chiefly indebted to their climate, for the abundant supply of the vegetable market to their peculiar cookery, and for the excellence of their written works rather to the ingenuity of a few clever men, than to the general habits of the community. In flowers their taste is rather that of the Romans than of other European nations, for they are contented with a few showy kinds of sweet-smelling flowers, especially roses. Their great public gardens remind one of the days of Henry VIII., and if it were not for the imposing effect produced by the architectural grandeur of the buildings with which they are associated, they would be quite contemptible as works of the nineteenth century. There no doubt are exceptions to this statement, but as a general fact it cannot be contradicted. The Garden of Plants at Paris, which is the largest of the public establishments in France to which the name of garden properly applies, is not an exception to this statement, so far as the plants it contains are concerned. In 1818 it consisted, in the open air, of departments devoted to various purposes of teaching; there was an indifferent collection of hardy herbaceous plants, and hardy trees and shrubs, some puerile contrivances to aid the student of agriculture: the plants in the houses were ill cultivated, few in number for such a place, and altogether unworthy of the reputation the garden had gained. Since that period two large hothouses have been built, 72 feet long, 42 feet wide, and about 50 feet high, with iron span roofs and heated by steam, and undoubtedly the establishment is progressing to a better state. But even now there are few judges of gardens who would assign the Jardin des Plantes a place among the first class of European gardens.

In Great Britain it has never been the policy of the government to offer direct encouragement to either science or art, except in an uncertain and sparing manner, but rather to throw the duty of fostering them upon the people. So far as gardening is concerned the government has been right; for if in this country such public gardens as we have enumerated are unknown; on the other hand no part of the Continent possesses such multitudes of good private gardens as Great Britain. That which in other countries is a luxury, provided for at the public expense, is here rendered a kind of necessity, which all persons, from the cottager to the noble, strive to possess. Nothing can be more beneficial to the community, or more advantageous to horticulture itself, than this difference, for the result is not here and there a magnificent garden, and all round it comparative sterility, but a universal garden all over the country. The chief English garden containing a large collection of plants is that of Kew, which is certainly the richest in the world in New Holland plants, and which was, during the late war, almost the only place in Europe to which exotic plants were introduced in considerable quantity. It contains a bad and ill-named or rather unnamed collection of hardy plants, and a good many small hothouses and greenhouses filled with rare plants; there is moreover an excellent kitchen-garden and forcing department. In consequence of this establishment having had a monopoly of government support for above 30 years, it has been the channel through which an enormous quantity of new plants have been introduced to Europe from all parts of the world. For many years however it was unworthy of the nation, from the illiberal manner in which it was conducted, a system of exclusive possession having been observed in it, which was most disgraceful to those by whose authority it was maintained, and who acted as if such gardens were supplied by the public purse for the private gratification of a few selfish courtiers, and not for either the crown or the country. Of late years however this system has been abandoned, a liberal management has been introduced, and the collection is as accessible as that of other nations. Next in importance among public gardens is that of the Horticultural Society, at Chiswick, near London. It was established at the expense of the members of the society, and was intended both as a place of experimental researches in horticultural science, and as a station whence the most valuable, useful, and ornamental plants of all kinds, might be distributed through the country; for which purposes its extent, amounting to 33 acres, was expected to be amply sufficient. It has now been instituted 17 years, and consists of—1, an Arboretum, probably the richest in Europe in trees and shrubs that are ornamental; 2, of an orchard, beyond all comparison the most perfect collection of fruit-trees, of all descriptions, that has ever been formed; 3, of a few forcing-houses, now chiefly employed in the determination of the quality of different kinds of grapes; 4, of a kitchen-garden, in which trials are made of new vegetables, or of new methods of cultivation; but which is principally used as a school of practice for the improvement of the young gardeners in this branch of their art; and 5, of a few small hothouses and greenhouses filled with rare plants. It is moreover conducted as a kind of normal school for young men intended for gardeners, who are now obliged to pass an examination in the principles of their business before they are recommended to places. It was originally intended to erect a magnificent range of hothouses, but the mismanagement of the funds of the society by the late secretary has prevented that object being yet accomplished; it is however generally understood that this part of the plan, so far from being abandoned, will actually be commenced in a few months, now that the resources of the corporation have been invigorated by a more prudent and careful management. Even as it is, no association of individuals ever produced so marked an effect upon gardening in a few years as has been brought about by the enormous distributions of cuttings of improved fruit-trees, of the finest kinds of vegetable seeds, and of new plants mostly imported direct from the British colonies and from the west coast of America, made annually from the society's gardens, independently of the collections sent in return to all parts of the world.

The botanic garden of Edinburgh is one of the finest and best-managed in Europe. It consists of 16 acres, delightfully situated, and includes everything that can be required for the purposes of teaching. The houses are remarkably good, and the healthy condition of the plants deserving of all praise. It is particularly celebrated for its beautiful specimens of heaths. Besides these, there are botanic gardens at Glasgow, Liverpool, Cambridge, and Oxford; fine public gardens in the towns of Sheffield, Manchester, and Birmingham; and a garden at Chelsea, belonging to the Apothecaries' Company, who maintain it for the use of the medical students of the London schools. The latter was once among the most celebrated in Europe, having been for nearly 50 years under the management of Philip Miller, the author of the 'Gardener's Dictionary,' and whom Linnæus called the 'prince of gardeners.' Its situation has however become unfavourable for a garden, in consequence of the number of houses with which it is surrounded; and the collection had latterly fallen into some disorder; but a commencement has lately been made by the present professor to re-arrange it, and it may again be expected to become an efficient school of botanical instruction.

The number of species included in Loudon's 'Hortus Britannicus,' or catalogue of the plants either cultivated in Great Britain or indigenous, amounted in 1830 to upwards of 25,000, exclusive of Cryptogamous plants; and although a vast number of deductions must be made, it is not improbable that there are at this time nearly as many species known in the different British collections.

GARDEN HUSBANDRY is a branch of Horticulture, the object of which is to raise fruits, vegetables, and seeds for profit on a smaller extent of ground than is usually occupied for the purpose of Agriculture.

The best examples of this kind of industry are found among the market-gardeners near populous towns, particularly London, Paris, and Amsterdam. By the application of much manual labour and an abundant supply of manure they accelerate the growth of vegetables, and produce them more abundantly than where manure is not so easily obtained, or where there is not so large a demand for the produce.

The gardeners near Paris, some of whom have gardens within the outer walls of the city, are called *Maraichers*, from the situation of their gardens in a low district which

was formerly a marsh (*marais*). The industry of this laborious class is proverbial. Their whole life is devoted to their gardens. They work the whole day in the greatest heat of the sun, and long before the rest of the inhabitants awake they are on their way to the market with their produce. The soil in which they raise their vegetables is naturally a poor sand, but by constant manuring it has been converted into a very rich mould abounding in humus. From its porous nature, and the frequent recurrence of dry summers, it would produce little without constant and abundant watering. The raising of water from numerous wells dispersed through the grounds, and conveying it to the growing plants, is the most laborious part of the work: during the whole summer this labour is incessant. There are large stone cisterns in which the water is allowed to remain that it may acquire the temperature of the air; and from these it is carried by pipes into various channels which intersect the garden in every direction. These gardeners divide the season into three periods. The first begins in October, when they sow lettuces in a hot-bed, which are pricked out a month after, and planted finally in a sheltered border about the end of January, the ground having been well dug and abundantly manured with very rotten dung taken from the hotbeds. At the same time they sow radishes and leeks among the lettuces. The radishes are sold by the end of March, the lettuces in May, and the leeks in June. This completes the first season. The ground is now dug again, and manured with fresh long stable dung mixed with the earth of which the hotbeds were formed; in this they plant alternate rows of endive or scarolles (both varieties of chicory), and of cucumbers, which produce gurkens for pickling and sauces. The endive is sold in July, and the small cucumbers continue to be gathered till September. In the third season, which is the shortest, another digging and dunging is given, after which they sow radishes and small winter-salad, of which the French have a great variety. Winter endive is also planted for blanching. From this statement it appears that the ground produces a constant succession of culinary vegetables, and that it is manured thrice in the year. The great object is to have a rapid succession, and to allow no plant to occupy the ground long. Cabbages, cauliflowers, asparagus, artichokes, and other vegetables which remain a long time on the ground, are cultivated at a greater distance from Paris, where the land lets at a lower rate. These plants will bear to be carried to a greater distance than the delicate vegetables which are used chiefly in a raw state as salads. The only perennial plant in the gardens of the Maraichers is sorrel, of which there is a great consumption. This is continually dunged and watered to accelerate its growth, and is cut many times in the season. It must however be allowed that this forcing with manure and water, although it produces large and delicate fibres, does not give the flavour which belongs to vegetables grown in common earth, and which have had a more natural growth.

The market-gardens near London are on a larger scale, and if they produce fewer salads and pot-herbs, they produce better and more substantial vegetables, and likewise a considerable quantity of fruit. Mr. Middleton in his 'View of the Agriculture of Middlesex,' (London, 1813), gives an account of the management and produce of the gardens near London, which chiefly supply Covent Garden market.

The best soil is a moist alluvial loam deposited from repeated overflowings of the Thames, which are now prevented by banks or dykes. But an increased demand for vegetables has caused much inferior soils to be cultivated as gardens, and increased labour and manure have supplied the deficiency in natural fertility. The gardeners' year properly begins in autumn, when the land is dug, or rather trenched, and well manured. Various vegetables, which will be required in winter, are now sown, and especially those which are to produce plants to be set out in spring: spinach, onions, radishes, and winter salads are sown, and when the weather is severe, are protected by a slight covering of straw or mats. In February, the cauliflowers which have been raised in frames or under hand-glasses are planted out. The cabbage plants are pricked out. The radishes, onions, and salads go to market as soon as they are of sufficient size, and sugar-loaf cabbages succeed them. As the cauliflowers are taken off, they are succeeded by endive and celery, and the same is the case with the cabbages. Thus there is a constant succession of vegetables, without one moment's respite to the ground, which, in consequence of continual stirring and manuring, maintains its productive power. Deep trenching in some degree prevents that peculiar deterioration of the soil which would be the consequence of the frequent repetition of similar plants. This effect is most perceptible when the plants perfect their seed, which is seldom or never allowed to take place in market-gardens; but great attention is paid to the species of plants which succeed each other on the same spot. The principle which experience and theory unite in establishing, is that of avoiding the too frequent recurrence of plants which belong to the same natural families. The greater variety cultivated in gardens, in comparison with the common produce on a farm, enables this principle to be fully acted upon. Those gardeners who overlook this, and repeatedly sow or plant the same kind of vegetables in the same spots, are soon aware of their error by the diminution of the produce, both in quantity and quality, and by various diseases which attack the plants, however abundant may be the food supplied to them, or careful the tillage.

The principle on which the gardens are cultivated, is that of forcing vegetation by means of an abundant supply of dung, constant tillage, and occasional watering. The whole surface is converted into a species of hotbed; and crop succeeds crop with a rapidity which is truly astonishing. Those vegetables which arrive at a marketable state in the least time are always the most profitable, and those also for which there is a constant demand at all times of the year. With an abundant supply of manure, the market-gardeners have no fear of exhausting the soil; and dissimilar vegetables may grow together on the same ground. Trees bearing fruit may be planted in rows, especially those of the dwarf kind; and under them those vegetables which do not require much sun may be raised to advantage. This is a very common arrangement in the market gardens near London. Raspberries, gooseberries, and currants, are planted in the rows between the trees. These rows being thirty or forty feet apart, leave ample room for vegetables. But in those gardens where the finest vegetables are raised, and particularly in those which are appropriated to the growth of seeds, no trees are permitted to shade the ground: even the hedges, if there are any, are kept low and clipped, that they may not give any shade, or harbour small birds. The market-gardeners near London do not raise many peas or beans, except such as are forced and require glass frames to protect them. The chief supply of peas in the season comes from a greater distance, and is the produce of whole fields sown for that purpose by the farmers within a moderate distance of London. This crop would not be so profitable in a confined garden cultivated at a great expense.

The value of the produce in one year, from an acre of garden-ground in the most favourable situation, as stated by Mr. Middleton, from the account which he received from a market-gardener, is almost incredible. It is as follows:—radishes, 10*l.*; cauliflower, 60*l.*; cabbages, 30*l.*; celery (first crop), 50*l.*; (second crop), 40*l.*; endive, 30*l.*: making a total of 220*l.* for the gross produce of an acre in twelve months. The expenses of cultivation are very great. In inferior situations, the produce is much less, but the expenses are also somewhat less. When it is considered that there are nearly 2000 acres thus cultivated, the gross amount of produce must be very great.

A garden should always be laid out in a regular form, with narrow parallel beds, and paths between them. One or more roads, of sufficient width to allow a cart to pass, should intersect these beds at right angles, for the convenience of bringing manure and taking off the produce. The beds should not be above six feet wide; so that a person may easily pull up weeds, or gather the vegetables without treading upon the beds. The surface-soil taken from the paths serves to raise the beds, and in retentive soils may carry off the superfluous water after sudden and violent rains. The whole ground should have been trenched two spits deep or more; and this trenching should be frequently repeated, to mix the upper with the under part of the soil, and distribute the decomposed dung throughout the whole depth. Thus in time a rich black mould will be produced, in which every kind of vegetable will grow most rapidly. For early plants, and those which are used in winter, and require to be protected from frost, narrow beds are made lying in a direction east and west, and sloping towards the south, with the north side raised high, so that their surface forms an angle of twenty or thirty degrees with the horizon. This gives the plants a protection from the north winds, and

exposes them more to the influence of the sun. In very frosty weather, these beds are covered with mats or loose straw. We do not mention frames covered with glass, as they belong to a higher kind of horticulture: but a moderate hotbed made with fresh dung, and covered with mats laid over hoops, is indispensable for the raising of early vegetables. By these means radishes and various salads may be raised very early in the spring, and sometimes, in mild winters, without any interruption during the whole year.

An abundant supply of manure is indispensable in a market-garden, and this can generally be obtained in large towns at a trifling expense. The neighbourhood of a town is therefore a necessary circumstance towards the production of the crop, as well as its sale. It would be impossible to make a sufficient quantity of manure by means of the horses which are employed to carry the produce to market; and the extent of land usually laid out in garden-ground could not raise sufficient food for cattle, without taking up a space which may be more profitably employed. The only animal which can be kept to advantage by a gardener is a pig. This animal will live well on the offal of vegetables; and the gardens of cottagers could not well be kept in a fertile state if it were not for the manure made by the pigs.

The market-gardeners about Amsterdam are mostly Jews, and the vegetables which they bring to market are similar to those of the London or Paris gardeners; but they excel particularly in raising cauliflowers, large white cabbages for making *saur-kraut*, a dish much relished in the winter by the Dutch and Germans, [Cabbage,] French beans, cucumbers, and melons. They raise these last in such abundance, that heaps of them are sold in the markets at a very low rate. They also excel in the forcing of early peas and beans, and in the general management of hot beds.

The profits of a garden near London, of the extent of ten or twelve acres, are as great as that of a farm of ten times the extent cultivated in the best manner, without the help of purchased manure. But if manure can be obtained at a reasonable rate, as is often the case in great thoroughfares, where many horses are kept for public conveyances, although there be no immediate demand for vegetables, a garden may be very profitably cultivated, entirely for the purpose of raising seeds. This branch of industry is the more worthy of notice, as it may enable a cottager to improve his situation greatly by the produce of a small garden or allotment of land. The demand for seeds of all the most common productions of a garden, and especially of flowers, is great beyond belief, and the profit of those who retail them in small quantities is so great that they can afford a liberal price to those who raise them with proper care so as to keep the varieties distinct.

In some agricultural districts it is the custom for the labourers to plant turnips in their gardens in November, in order to obtain the seed in time for sowing in the next year. They choose the soundest and best shaped, and by attention in keeping the ground clean, and allowing only one sort to go to seed within a certain distance, they produce a better seed than the farmer could; because the labourer and his family having their garden constantly in view, can more easily keep off birds and watch the ripening of the seed, so as to allow it to come to perfect maturity, without danger of the pods bursting, and shedding the seed from being left too long. Thus they can collect a bushel or two of excellent seed from a small portion of land; and this, at the price of a guinea a bushel, which is cheaper to the farmer than if he raised it himself, or purchased it of the seedsman, is a very profitable crop to the labourer. An industrious cottager, without losing any time, with the help of his wife and children, may much increase his comforts in this manner, while at the same time he trains his children in habits of industry. To no class of men would a knowledge of garden husbandry be more useful. The improvement which may be made in the condition and character of the poor, by combining in their education a knowledge of the most common arts of life with that of letters, which is often the only thing taught in schools, must be evident to every man who has reflected on the subject; and of all these arts the most generally useful amongst an agricultural population is the art of horticulture. The cottager who is acquainted with the means of raising early garden produce, who can graft young trees, who knows what plants may be propagated with a little care, and be readily sold when in perfection, can employ his labour with a double advantage. And many a man, from a very small beginning, has, with a moderate share of judgment and prudence, raised himself to independence, if not to affluence; while he that plods on in the beaten track like a horse in a mill ends his days in ignorance and poverty.

The great superiority of those schools which have been established to teach the children of the poor to work as well as to read, over those which teach book knowledge only, is indisputable. A boy who can manage a little garden, who takes a pleasure in watching the seed he has sown, who plucks out every weed as soon as it appears, and who prides himself on the fruit and vegetables which he can place on his father's table, is more advanced in his education than he who can only read and write, however well he may do both.

Many plans have been proposed for the distribution of the crops in a cottage garden; but none of them are suited to every situation. Much depends on the nature of the soil, which may be better suited to one kind of produce than another; and also to the demand for any peculiar class of vegetables. New sorts may often be introduced with advantage. The raising of any useful plant with great care will often give a man a reputation, which makes it advantageous to him to confine himself to these principally, and raise them in the greatest perfection. An ingenious man will find out what is most for his own advantage; and from the list of plants which may be cultivated for ornament or for use a selection may be made which may be well suited to the situation of the ground and the circumstances of the grower. The practice of the market-gardeners may be examined with advantage; and long experience, with the test of profit, will lay down better practical rules than the most plausible theories.

An allotment of land such as is now very frequently given to agricultural labourers with the laudable intention of making them more industrious and independent of parochial relief, may be cultivated to great advantage by applying judiciously the general principles of garden husbandry. There are few cottages which have not already attached to them a small garden of a few perches, in which common vegetables, such as cabbages, onions, and early potatoes, are raised. The same vegetables may continue to be cultivated there, provided the situation is more convenient from its proximity to the cottage, or a small part of the allotment may be set apart every year for this purpose, so as to change the crops, which is always an advantage. But the remainder of the allotment should be cultivated on a regular plan, as a farm in miniature, with this difference, that all the operations should be performed with the minute attention of a gardener. Potatoes and wheat, if the soil is not too light for the latter, or rye, in very sandy soils, will be the principal crops, being immediately necessary to the support of the family. These crops have sometimes been recommended to be raised in every alternate year; but whatever be the tillage or manuring, there are few soils which will not soon be reduced in fertility by this constant succession. One-fourth of the land in wheat, and one-fourth in potatoes, is the utmost which can be profitably cultivated in one year. The remaining half of the allotment must produce pulse, roots, and green crops, by which animals may be fed and manure collected. An allotment of three acres will enable a cottager to keep a cow, by having a portion of it in clover or other artificial grass. In the 'Farmer's Magazine' for February, 1802 (p. 38), there is an article drawn up by Mr. John Sinclair, in which it is shown how this may be effected without difficulty. But as the allotments usually given to labourers seldom exceed half an acre, or at the most an acre, the keeping of a cow is out of the question; and the only animal which can be profitably reared and fatted is the pig, to which we shall therefore confine our observations. By means of pigs the cottager may greatly increase the profit which can be made from his allotment of land, keeping up at the same time a proper degree of fertility. One-half of his land must be cultivated to feed his pigs; besides the smaller potatoes which remain when the finest and best are taken out for the use of the family, he may give them beans, barley, carrots, parsnips, and turnips, especially the Roota Baga, or Swedish turnip; and all the straw must be used for litter. If this be strictly attended to, the greatest possible profit will be made from the land, without any danger of its being exhausted and loosing its fertility. The rotations will therefore be—potatoes, with a great quantity of manure; then barley, then peas, beans, carrots, parsnips, and Swedish turnips,

manured; and after these wheat. The application of the garden husbandry must be in the preparation of the soil by deep trenching and digging, carefully drilling or dibbling all the seeds in rows, stirring the soil between the growing plants, and keeping the ground clear of weeds by the hand and the hoe. These last are the most essential part of the cultivation, and are to be performed by the wife and children. By daily attention to the progress of the plants, and continual assistance at critical periods, sometimes thinning out, and at other times transplanting to produce an equal crop, and treating every plant as if it were a rare plant in a garden, the ground may be made to produce more than double what the most attentive farmer could expect on a larger scale. The additional labour, which is all light, costs the cottager nothing; but the farmer could not afford to pay for it at the usual rate of wages. If he could find hands to do it, he could not insure the minute attention which is naturally applied when the labourer is to receive all the advantage himself. The comfort which a well-managed allotment gives to a labourer with a numerous family is hardly credible by those who have not witnessed it; and if there were less profit, it would still be highly beneficial, in a moral and political point of view, that early habits of industry should be encouraged, and that the temptations which arise from want of employment should be taken away from the young by the useful and healthy occupations of the garden.

GARDINER, STEPHEN, Bishop of Winchester and Lord Chancellor of England, although he was called by another name, was believed to be the illegitimate son of Dr. Woodvil, bishop of Salisbury, who being brother to Elizabeth, Edward IVth's queen, was also related to Henry VIII. He was born at Bury St. Edmunds in 1483. His studies at Trinity Hall, Cambridge, were directed not only to Latin and Greek, but also to civil and canon law, and it was partly his skill in this latter branch of learning that led to his future greatness. When master of Trinity Hall, through his intimacy with the Duke of Norfolk he became acquainted with Wolsey, who afterwards made him his secretrary, and in this capacity he was brought under the notice of the king, with whom he rapidly ingratiated himself. An office of trust was soon committed to his charge. Dr. Stephens (as Gardiner at this time was usually called) was sent to Italy in 1527, to procure the pope's consent to the divorce of Catherine of Aragon, and no better proof can be given of his high favour with Henry than the fact that from Rome he wrote a letter to the king so private that even Cardinal Wolsey was not to see it. (Burnet's *Reformation*, where the letter is given.) Though he failed in the object for which he was sent to Rome, he rendered services at this court both to the bishop of Norwich (who afterwards rewarded him with the archdeaconry of Norfolk), and to Wolsey by promoting his interests as a candidate for the papal throne. He was recalled from Rome to manage the process for the divorce in England; and because he was esteemed the greatest canonist of his time, the king would commence no proceedings until he returned. After his arrival he was made secretary of state, and having in the spring of 1531 been further advanced to the archdeaconry of Leicester, was installed bishop of Winchester in the following November. We pass over his embassies to France and Germany in order to speak more fully of his opposition to all such measures as were intended to procure a religious reformation in England. Gardiner was attached to the doctrines and forms of the Roman Catholic church; he was believed to have already reconciled himself to the pope, with whom he had had differences while urging the divorce: and he had no sooner returned to England than he urged the king to punish the sacramentaries (persons who denied the corporal presence of Christ in the eucharist) and to turn a deaf ear to the proposals of the reformers. It was impolitic, he said, to offend the pope, not only on account of the power of the holy see itself, but because the emperor would break off all commerce with him if he went to extremities against the Roman Catholic religion.

His advice was partially taken, the innovations of the reformers were obstructed, and Lambert and others were condemned and executed for their heretical opinions. 'He was opposed' says Burnet, 'to *all* reformation:' both the free use of the Scriptures and their translation into English he considered to be highly objectionable; to the disuse of confession and the omission of certain sacraments he was equally averse; and he was altogether opposed to the measures of Cranmer and his associates. He had certainly endeavoured to dissuade the king from listening to Cranmer's proposals for furthering the Reformation. The emperor, he said, threatened to break off all commerce with him, if he went to extremities against the Roman Catholic religion. In the promotion of the act of the six articles (1538), and in the subsequent enforcement of its provisions, the extent of his hostility to the reformation was most evidently displayed. The decline of Cromwell's power tended greatly to increase his authority and influence. Both these crafty statesmen had at the same time been servants to Cardinal Wolsey, the one as his secretary, the other as his solicitor, and both had risen through Wolsey's patronage: but as they had espoused opposite parties, their friendship was at an end, and Gardiner's jealousy of the vicar-general was without bounds. When circumstances [CROMWELL] weakened the king's confidence in the bishop's unpopular rival, he craftily assisted in his downfall, and prepared to occupy his place in the good graces of the king: the fate of Cromwell was soon sealed; a fallen favourite has few friends, and crimes were soon proved which ensured his execution (1540). It now became Gardiner's object to use all means to obtain the favour of the king. The disgust of Henry at his new queen, Anne of Cleves, was so rapidly conceived that he had scarcely married her before he began to talk of a divorce. There was no just ground whatsoever for such a separation: nevertheless Gardiner, though an accurate lawyer, promoted the king's suit. The divorce was procured, but Henry, though well aware of the assistance that Gardiner had rendered to his cause, did not wholly trust him. A perception of his excessive cunning appears to have estranged his confidence. The abilities of Gardiner were undeniable; he had also a powerful party at his side: nevertheless he could only obstruct and hinder, not wholly set aside, the measures of his opponents. The king befriended Gardiner, but he never ceased to befriend Cranmer also.

An evidence of his friendship for Cranmer is shown by his conduct to the archbishop on an occasion in which his life was in danger. The Roman Catholic party, with the bishop of Winchester at their head, attempted to attach the crime of heresy to Cranmer; but the king himself delivered a message to him to prepare him for the threatened attack, taking care afterwards to appoint such a tribunal to investigate the charges as should defeat the object of his accusers. The popularity of Gardiner indeed was not injured by the failure of this conspiracy; his restless spirit however was soon employed in another scheme, the consequences of which were not equally harmless to him. The queen (Catherine Parr) who was secretly a great favourer of the reformers, and had admitted their preachers into her apartments, in conversation with the king, whose illness added to his ordinary impatience, maintained the new doctrines, discoursing very warmly upon the subject. This vexed the king, who communicated his displeasure to Gardiner, who to please his master (as he thought), now began to plot against the queen, going so far as to write articles of impeachment against her. In this attack the chancellor was associated with him; and through an accident occasioned by him, the queen discovered the conspiracy, and was able to defeat its end. The chancellor inadvertently dropped within the palace the paper on which the articles of impeachment were written: it was picked up and given to the queen by one of her women, and by her good sense and character, which gave her great influence over the king's mind, coupled with considerable adroitness of management, she escaped the accusation. The day had been named for carrying her to the Tower; but when her accusers came before the king he railed at them with the most violent abuse. Gardiner wes never able to regain his favour or his countenance. (Burnet.)

At Henry's death Gardiner experienced a still greater reverse. The young king and his government proceeded to make further religious changes; the use of holy water was decried, and homilies were composed which the clergy, who had abused their power of preaching, were ordered to substitute for sermons: a general visitation also was ordered, at which the new articles and injunctions were to be circulated. These things offended Gardiner, and he totally condemned them in no measured terms. If this behaviour was rash, it was also high-spirited and consistent. The consequences followed, as might have been foreseen. The

council, on his refusal to comply with their injunctions, committed him to the Fleet. Here he was confined until the act of general amnesty, which passed in the December after the accession of Edward, released him. As soon as he was free he went down to his diocese, and while there he remained unmolested; but on his return to London, on account of a certain sermon which he preached on St. Peter's Day, he was seized and committed to the Tower (1548). Various conferences were held with him, and his release was promised him on condition that he would express his contrition for the past, promise obedience for the future, subscribe the new settlement in religion, also the king's complete power and supremacy, though a minor, together with the abrogation of the six articles. With the first of these conditions alone did he absolutely refuse to comply. The terms of liberation were afterwards rendered still more difficult. The number of articles that he was called upon to subscribe was considerably increased. On his refusal to sign them, his bishopric was sequestered, and he was soon afterwards deprived. For more than five years he suffered close imprisonment, and it was not until the beginning of the reign of Mary that his liberty was restored (1553). If his fall from power at the conclusion of Henry's reign had been great and sudden, still greater and still more sudden was the rapidity of his reinstatement. A Catholic queen was on the throne, and he who had been ever the foremost of her partisans must necessarily be raised to be one of her first advisers. The chancellorship was conferred upon him. His bishopric was restored, and the conduct of affairs placed in his hands. The management of the queen's marriage treaty was intrusted to him. He was chosen to officiate at her marriage, as he had also done at her coronation, and became her most confidential adviser. No matters, whatever they might be, could be proceeded in without his privity and concurrence. We must refer our readers to the ecclesiastical and general histories, and to Burnet's 'History of the Reformation,' for an account of his share in the persecutions of this reign. Those horrors which were not committed by his actual orders must at least have obtained his sanction; for he had reached a height of power, both civil and ecclesiastical, perhaps unequalled in this kingdom, except by his master Wolsey alone. He died on the 12th of November, 1555. His funeral was conducted with great pomp and magnificence. A list of his writings is given in Tanner's 'Bibl. Britannica,' Hibernica, p. 308.

The character of Gardiner may be stated in a few words. He was a man of great ability; his general knowledge was more remarkable than his learning as a divine: he was ambitious and revengeful, and wholly unscrupulous; his first object was his own preservation and advancement, and his next the promotion of his party interest. He saw deeply into the characters of those with whom he dealt, dealt with them with infinite tact, and had an accurate foresight of affairs. (*Ecclesias Hist.*; Burnet's *Reform.*; &c.)

GARFAGNA'NA is a highland district of the northern Apennines, on the borders of the states of Tuscany, Genoa, and Modena, including the valley of the Upper Serchio above its junction with the Lima. The valley extends from the sources of the Serchio in a south-east direction for about twenty-four miles between the main ridge of the Apennines and the lofty group called Alpe Apuana, which divides the valley of the Serchio from that of the Magra, and also from the maritime districts of Carrara, Massa, and Pietrasanta.

high. The climate of Garfagnana is cold and foggy, and exposed to boisterous winds from the mountains. The inhabitants of this secluded district amounted in 1832 to 40,160. The low lands of the valley produce some corn, hemp, and flax, and in some sheltered and favoured spots the olive and mulberry: but the main resource of the people is their pastures and their forests of chestnut-trees, the fruit of which is to them a substitute for bread. In 1832 they had 8836 head of horned cattle, 47,505 sheep, 6958 goats, 1867 pigs, 255 horses, 624 asses, and 172 mules. In the same year they exported 40,000 lbs. of silk cocoons; other exportations are cheese, undressed skins, chestnuts, wool, and timber. There are also iron and coal-mines. The Garfagnana contains sixty-seven parishes, and is divided for administrative purposes into six jurisdictions, three of which belong to the duchy of Modena, two to the duchy of Lucca, and one to Tuscany. The principal towns are—1. Castelnuovo, with 2400 inhabitants, and some good buildings, being the residence of the Modenese governor; it has a college, an hospital, and a Monte di Pietà. The poet Ariosto was at one time governor of this place, of which he gives a curious account. [ARIOSTO.] 2. Gallicano, with about 1000 inhabitants, the head place of the district, and belonging to Lucca. 3. Barga, with 2500 inhabitants, head town of the district, and belonging to Tuscany.

GARLIC, a hardy perennial plant with bulbous roots, found growing wild in the island of Sicily, and in several other parts of the south of Europe. In gardens it is cultivated chiefly on account of its bulbs, which are much used in cookery, and occasionally in medicine.

It is the *Allium sativum* of botanists, and is regularly grown for the market. For this purpose, a light tolerably rich soil is selected in a dry warm situation. The ground should be well dunged for the crop which precedes garlic; and not when the garlic is planted, because, when this is done, the bulbs are very apt to canker and to be infested with maggots.

It may either be planted in beds or in rows; if in beds, the distance between the plants may be seven or eight inches; if in rows (which is most recommended), they may be one foot apart, and six inches between the plants in the row. In gardens where the soil is light and dry, the best season for planting is late in autumn; but where the soil is wet, the operation should be deferred until spring, that is, to any time in February or March.

The plant is propagated by offsets, which it produces annually in considerable numbers, and which are commonly called cloves. The season of ripeness, which is generally in the end of July or August, is easily known by the leaves changing from green to yellow. At this period the bulbs should be taken up and spread out in the sun to dry, after which they may be tied in bunches and kept in a dry house for winter use, in the same way as onions.

GARNET, a well-known precious stone, of which there are many varieties. Some of them are probably distinct species; but agreeing in form, and some other properties, they are classed together. This mineral occurs crystallized, massive, and granular. The primary form is a cube, but it occurs in the form of a rhombic dodecahedron. The colour is various, and accordingly, as will be seen below, it has received different names. It is transparent, translucent, rarely opaque. Lustre vitreous, resinous. Specific gravity, 3·6, 4·2. Hardness, 6·5, 7·5. Cleavage parallel to the planes of the rhombic dodecahedron; fracture, uneven.

This mineral occurs in the mountainous parts of most countries.

The massive varieties are amorphous, structure granular, compact. The crystalline varieties, according generally to their colour, have received various names. Precious garnet, *Almandine*; black, *Melanite, Pyreneite*; greenish-yellow, *Grossularia*; yellow, crystallized, *Topazolite*; granular, *Succinite*; brownish-yellow, granular, *Colophonite*; greenish, compact, *Allochroite*; red, *Pyrope*, *Carbuncle*; reddish-brown, *Essonite*, *Cinnamon-stone*, *Romanzovite*; magnesian, *Rothoffite*.

The following are the analyses of the almandine, by the authors named, and from the places mentioned:—

	Bohemia.	New York.
Silica	33·75	42·51
Alumina . . .	27·25	19·15
Oxide of Iron . .	36·00	33·57
Oxide of Manganese	0·25	5·49
Lime . . .	0·00	1·07
	97·25 Klaproth	101·79 Wachtmeister

It appears that the essential ingredients of the garnet are silica, alumina, and oxide of iron; these are frequently partially replaced by oxide of manganese, lime, and magnesia.

GARNET, HENRY, superior of the Jesuits in England, was the son of a schoolmaster at Nottingham, and was born about the year 1554. He was educated in the Protestant religion at Winchester College, whence it was intended that he should go to New College, Oxford, and his not having done so has been assigned to different causes by Protestant and Catholic writers. He removed from Winchester to London, where he became corrector of the press to a celebrated law-printer; and having turned Roman Catholic, travelled first to Spain and thence to Rome, where he entered the society of Jesuits in 1575. In the Jesuits College, at Rome, he studied with great indus-

try, became professor of Hebrew and teacher of the mathematics, and obtained such credit, that in 1586 he was appointed to the English mission. Two years afterwards he was name Superior of the English Jesuits, the duties of which office he discharged with zeal and punctuality. For several years previously to the Powder Plot he remained in the neighbourhood of London, following various occupations in order to disguise his real calling. He was well known to have been implicated in the treasonable intrigue with the king of Spain immediately before the death of Queen Elizabeth, and was suspected of other seditious practices. In order to protect himself from penal consequences, he purchased a general pardon upon the accession of James I. His association with disaffected recusants exposed him to the continued suspicion of the government, who did not regard him more favourably for that he was intimate with many of the Catholic nobility, more especially with Lord Vaux, whose eldest daughter, Anne Vaux, after her father's death followed the fortunes of Garnet with singular attachment. In September, 1605, a pilgrimage to St. Winifred's Well, in Flintshire, was undertaken by Garnet, in company with persons who were actively concerned at that time in the promotion of the Gunpowder Plot; and it is suspected that this unusual proceeding must have had some reference to the great blow that in two months afterwards it was intended to strike for the Roman Catholic church. When the Powder Plot was discovered, Garnet was in the neighbourhood of Coughton, the general rendezvous of the conspirators; but he removed for greater safety to Hendlip Hall, near Worcester, at the request of one Hall, otherwise called Oldcorne, a Jesuit, who was domestic priest to Mr. Abington, the brother-in-law of Lord Mounteagle, and proprietor of that house. In Hendlip (*Beauties of England*, vol. xv. p. 184) were many secret passages and hiding-places which served for concealment, and to one of these Garnet and Oldcorne were soon forced to retreat; for Sir Henry Bromley, commissioned by lords of the council, invested the house, and vigorously searched every room. A bill of attainder was introduced into parliament, which recited that Garnet, Greenway, Gerard, Creswell, Baldwin, Hammond, Hall (Oldcorne), and Westmorland, all Jesuits, had been guilty of treasonable correspondence with Spain, after and before the death of Queen Elizabeth. Father Gerard fled to the Continent; Father Greenway also, after very narrowly escaping an arrest, landed in Flanders; but Garnet and Oldcorne were not so fortunate. Being cramped for want of space within their hiding-place at Hendlip, they were compelled to leave it after a confinement of seven days and as many nights, and were seized and conveyed to London (Feb. 12, 1606). The lords had now determined to proceed against them as conspirators in the Powder Plot. Evidence sufficient for their conviction had not yet been obtained, but every method was used to procure it, and these methods soon proved to be effectual. Oldcorne was tortured; Garnet's letters were intercepted: conversations were promoted between the two prisoners, who, while they thought themselves in private, were in fact secretly listened to by spies, who wrote down their words, and other unfair practices were also used; but for these, as for Garnet's view of equivocation (p. 315), we must refer to Mr. Jardine's curious account of Garnet's trial. (*Criminal Trials*, vol. ii) The guilt of both prisoners was proved: Garnet was hanged in May, 1606, in the city of London; Oldcorne had been executed at Worcester in the preceding month: they were both considered martyrs by the Roman Catholics.

It is certain that more English Jesuits than we have named were at least aware, if they did not take a part in the conspiracy, of the Powder Plot. It is also probable that there were persons upon the Continent who, through Fawkes, Bayham, or other conspirators, had become acquainted with the intended treason. But it does not appear that any body of Jesuits, either at home or abroad, were formally led to expect that an attempt was to be made to restore the Roman Catholics to power; much less by what means the attempt would be made.

GARNIER, JEAN JAQUES, was born in 1729, in the province of Maine, of poor parents, who gave him however a superior education. Without money or interest he left his home at the age of eighteen, and travelled on foot to Paris, where a happy chance made him acquainted with the sub-principal of the college of Harcourt, who perceiving his uncommon talents and acquirements, took him under his patronage, and procured him a situation at the abovementioned college. About 1760 he was appointed professor of Hebrew at the Collège de France, of which he afterwards became inspector. On the death of Villaret in 1766 he was appointed historiographer of France, in which capacity he published in 1770 the 9th volume, in 4to., of Vélly and Villaret's 'History of France,' beginning with the year 1469. Continuing his labours on this work, he produced the 13th volume, which brings the history of France down to the middle of the reign of Charles IX. He was the author of the following works:—'L'Homme des Lettres,' Paris, 1764, 2 vols., in 12mo., in which he lays down an ingenious method for forming a man of letters; 'Traité de l'Origine du Gouvernement François,' Paris, 1765, 12mo.; 'Le Commerce remis à sa Place,' 1757, 12mo; 'Le Bâtard Légitime, ou le Triomphe du Comique Larmoyant,' 1757, 12mo. He also wrote several papers in the 'Memoirs of the Academy of Inscriptions;' and among other subjects, on the philosophy of the antients, and especially on that of Plato, of which he was a great admirer. Garnier died in 1805, at the age of seventy-five.

GARONNE, a river of France (the *Garumna* of the Romans). [France, vol. x., pp. 408 and 423.] We here subjoin the official statement of the length of the navigation of the rivers which form the system of the Garonne.

	miles.
Garonne and Gironde	281
Tributaries of the Garonne, arranged in the order in which they fall into it:—	
Salat (right bank)	10
Ariège (do.)	19
Tarn (do.)	90
Gers (left bank)	1
Bayse (do.)	15
Lot (right bank)	190
Dropt (do.)	[illegible]
Dordogne (do.)	182
Tributaries of the Dordogne:—	
Vezère (right bank)	29
Isle (do.)	90
Tributary of the Isle:—	
Dronne (right bank)	1
Total navigation of the system of the Garonne	960

The navigation of the Garonne is in the upper part much impeded by a variety of obstacles, as rocks, and the trunks of trees that have been rooted up. These obstacles continue below Toulouse, and even below the confluence of the Tarn. At Bordeaux the river forms a fine haven, capable of containing 1000 sail of ships. The tide rises here from 12 to 18 feet, and flows considerably higher up the stream: it is perceptible at St. Macaire, about 24 or 25 miles above Bordeaux, where there is a considerable bend in the river. The conflict of the tide coming in with the descending water in the Gironde is fearful: boats are in danger of being carried from their moorings and swamped by it. The French call this phenomenon '*Le Mascaret*.' There are several sandbanks in the Gironde.

The Garonne serves for floating timber, and (on rafts) blocks of stone from the Pyrenees, from the point where it enters France; for its source is beyond the frontier, in the kingdom of Spain.

GARONNE, HAUTE, a department in the south of France, deriving its name from the river Garonne, which has the upper part of its course in the department. It is bounded on the north by the department of Tarn et Garonne; on the north-east by that of Tarn; on the south-east by those of Aude and Ariège; on the south by the kingdom of Spain, from which it is separated by the Pyrenees: on the south-west by the department of Hautes Pyrénées; and on the north-west by that of Gers. Its greatest length is, from north-east to south-west, 98 or 100 miles; its greatest breadth, at right angles to the length, is 63 miles. It is comprehended between 42° 39′ and 43° 54′ N. lat., and 0° 26′ and 2° 4′ E. long. Its area is about 2394 English square miles, being rather more than the conjoint areas of the English counties of Dorset and Wilts. The population, by the census of 1836, was 454,727, giving about 190 to a square mile. In extent it is a very little above the average of the departments; but both in absolute and relative population it very much exceeds the average, and also

far surpasses the English counties with which we have compared it. Toulouse, the capital, is on the right bank of the Garonne, in 43° 36′ N. lat., and 1° 26′ E. long., about 363 miles in a straight line west-by-south of Paris. It had in 1831 a population of 59,630; in 1836, of 77,372.

Surface; Hydrography; and Communications.—The southern part of the department is covered with lofty mountains, forming the principal range or the branches of the Pyrenees. The Pic Quairat, 9964 feet high, and Mont Carbère or Crabère, 8655 feet high, are in or close upon the border of the department. The lower slopes are covered with thick forests, or are occupied as sheepwalks or pasture grounds. The mountains are intersected by beautiful valleys, such as that of Luchon, and are crossed by the various ports or passes by which communication is kept up between France and Spain. The northern part of the department is occupied by hills of moderate elevation, separated by extensive plains.

The Garonne enters the department from the valley of Arran, in Spain, and traverses it in its whole length in a circuitous course from south to north.

The other rivers which water the department belong to the system of the Garonne: the principal are the Nesle, the Salat, the Ariège, the Lers, the Lougé, the Touch, the Save, the Gimone, and the Tarn.

The Canal du Midi, or Canal du Languedoc, commences in the Garonne at Toulouse, and follows the valley of the Lers into the department of Ariège. There is another small canal in the department, the canal of St. Pierre. The official return of the extent of water conveyance in this department is as follows:—

Navigation of Rivers.

Garonne	70 miles.
Salat	10 „
Ariège	19 „
Tarn	14 „
River navigation	113 miles.
Canals.	
Canal du Midi	32 miles.
„ of St. Pierre	1 „
Total water communication	146 miles.

The number of *Routes Royales* or government roads in the department is seven, in all states of repair and completeness; their aggregate length is nearly 200 miles. None of these roads are of the first class. One road of the second class, coming from Paris by Limoges, Cahors, and Montauban, crosses the department from north to south, through Castelnau and Toulouse to Pamiers (dep. of Ariège), and so into Spain. The other roads are of the third class.

There are about thirty *Routes Départementales*, or roads under the direction and at the charge of the local government, having an aggregate length of 476 miles; and a vast number of bye-roads or paths (*chemins vicinaux*), amounting in their total length to above 8000 miles. The *Routes Royales* are, on the whole, in tolerable repair; but of the *Routes Départementales* one-fifth only are in good repair. There are no railroads in the department.

Geology and Mineralogy.—The greater part by far of the department is occupied by the supercretaceous strata, which extend from the northern boundary to the junction of the Garonne with the Salat and the Nesle. The chalk formation does not rise to the surface: the oolitic or other formations between the chalk and the red marl or new (saliferous) red sandstone crop out from beneath the supercretaceous strata, and occupy a narrow belt to the south of these. The Pyrenees are formed of the older limestones and other primitive rocks. The various mineral treasures of the department are in a great degree neglected. There are ores of iron, copper, lead, antimony, bismuth, and zinc; slates, gypsum, and various species of marble and other limestones, and of granite. There are two brine springs and several mineral waters, of which the most celebrated are those of Bagnères de Luchon. [BAGNERES DE LUCHON.]

Climate; Soil; Agricultural Produce; Animals.—In the higher parts of the mountains the winters are severe and long; in the lower hills and plains, which make up the greater part of the department, the climate is mild; it rarely freezes, and a fall of snow is almost unknown. The medium temperature in winter is from 36° to 39° Fahrenheit; that of spring and autumn from 59° to 64°, and that of summer from 81° to 86°; the average number of days in the year in which rain falls is 100. The east and west winds predominate; the latter brings cold and rain. Tempests are frequent and violent. Catarrhal and rheumatic disorders and remittent fevers are common; goitres and diseases of the eyes are frequent in the mountainous country, especially on the banks of the Garonne.

The soil is thus divided:—mountains, 125,957 acres; heaths and moors, 81,502; rich loamy soil, 7,409; calcareous, 254,384; gravelly, 185,231; rocky or stony, 111,138; sandy, 338,355; clayey, 271,672; various, 152,033: total, 1,527,681 acres.

In the mountainous tracts it is only by dint of industry that any returns can be procured by the farmer. The most fertile localities are the neighbourhood of Toulouse, the productiveness of which in corn was noticed by Cæsar ('Locis patentibus maximèque frumentariis:' *De B. G.*, lib. i. 10); and of Rieux; and other parts of the valley of the Garonne: at Rieux two harvests are obtained in the year. The soil, according to its occupation, is distributed as follows: arable, 870,383 acres; meadows, 97,893; vines, 120,790; woods, 215,214; orchards, gardens, and nurseries, 13,749; osier and willow plots, 96; various, 7,841; heaths, commons, pastures, &c. 114,087; pools, ponds, ditches, 1,008; lakes, rivers, brooks, 11,551; forests, and non-productive occupations, 35,290; not accounted for, 39,779: total, 1,527,681 acres.

The arable land is chiefly devoted to the cultivation of wheat, maize, millet, rye, and other grains and pulse. The following is nearly the proportion in which the various kinds of grain are cultivated, taking as the basis of our calculation the official return of the quantity of land sown for the various crops in the year 1835. Wheat, 56·5 acres out of every 100 of arable; maslin, 3·5; rye, 9·5; barley, 1·; buckwheat, 1·5; maize and millet, 21; oats, 3; peas, beans, and other pulse, 3·5; potatoes, &c. ·5.

The quantity of wine grown in the department is considerable, though far from equal to what is grown in many other departments. The uplands and the valleys furnish abundance of excellent pasture; the mountains abound with wood, suited for ship-building.

Many oxen are bred in the extensive pastures of this department; also many asses and mules, which are much sought after by the Spaniards. There are sheep and swine; the poultry are good, especially that of Ile-en-Dodon. The geese and ducks are of great size; numbers of them are salted: the duck's-liver pies of Toulouse are highly esteemed by epicures. The care of bees and of silkworms appears to have been long declining. Game and wild animals are plentiful. In the mountains there are the wild boar, the roe-buck, the wolf, the fox, and other beasts; the heath-cock, and different varieties of the eagle. The partridge, the ortolan, and the quail, are taken in abundance in the plains. The rivers and lakes abound with fish; the lakes contain excellent trout.

Divisions, Towns, &c.—This department is composed of portions of Languedoc and of Gascogne (Gascony): Le Toulousain, or county of Toulouse (comprehending the dioceses of Toulouse and Rieux), a small part of the district of Le Lauraguais in Languedoc; and portions of the districts of Comminges, and of Couserans, and of Nebouzan, Les Quatre Vallées, Lomagne, Rivière, Verdun, and the county of Ile Jourdain, subdivisions of Armagnac in Gascogne, are comprehended within it.

It is subdivided into four arrondissements, as follows:—

Capital.	Population in 1831.	Population in 1836.	Situation.	Area, sq. miles.	Population of arrondis. 1831.	Population of arrondis. 1836.
Toulouse,	59,630	77,372	N.	612	139,927	159,064
Villefranche,	2,652	2,765	E.	359·5	61,251	63,101
Muret,	3,787	3,970	Central & W	604	86,709	88,994
St. Gaudens,	6,179	6,020	S and S.W.	818·5	139,969	143,568
				2,394·	427,856	454,727

The department comprehends 39 cantons and 599 communes.

In the arrondissement of Toulouse, besides the capital [TOULOUSE], there are Grenade (population, 2670 town, 4240 commune), a neat town on the Garonne; Villemur (pop. 3186 town, 6063 commune), an ill-built town; Bessières and Buzet, all on the Tarn; Castanet, near the Canal du Midi; Castelnau, on the road from Paris to Toulouse; Fronton, Montastruc, Verfeil, and Lavignac.

In the arrondissement of Villefranche are the chief town, distinguished from other places of the same name, as Villefranche de Lauraguais, Montgiscard, Montesquieu, Avignonet, and Baziège, all on or near the Canal du Midi; Caraman, Auriac, St. Felix, Revel (pop. 4540 town, 5456 commune), Lanta, Loubens, and Nailloux. Revel, situated on a height, which commands one of the most fertile and beautiful plains in the district, was, in the religious contests of the sixteenth century, one of the strongholds of the Huguenots. The fortifications were razed A.D. 1629.

In the arrondissement of Muret are the chief town, Muret, Martres, Cazères (pop. 1903 town, 2597 commune), where the navigation of the river begins; St. Julien, Carbonne, and Noé, all on the Garonne; Cintegabelle (pop. 3738 commune), Auterive (pop. 2000 town, 3172 commune), where the navigation commences, and Venerque, all on the Ariège; St. Sulpice, on the Lèze; Miremont, on the Mouillone: Grailhac, on the Marens; and Calmont, on the Lers, feeders of the same stream; Rieumes, Sainte Foy, and St. Lys, all on feeders of the Touch; Fousseret, near the Lougé; Montesquieu de Volvestre (pop. 2182 town, 3717 commune), and Rieux, formerly the seat of a bishopric, on the Arize, which flows into the Garonne; Montbrun, on a feeder of the Arize; and Le Plan, on the Volp, a small feeder of the Garonne. Muret is celebrated for a great battle fought under its walls in the 13th century. Pedro II., king of Aragon, and the Count of Toulouse, the protectors of the Albigeois, had besieged the town A.D. 1213. St. Dominic, who was shut up in it, called to his succour Simon de Montfort, general of the Crusade against the Albigeois, who with a much smaller force routed the besieging host; the king of Aragon fell in the battle. Earthenware and coarse woollen cloth are now manufactured at Muret and at Montesquieu de Volvestre.

In the arrondissement of St. Gaudens are the chief town, St. Gaudens: Valentine, which is so near to it as to be almost a suburb, St. Beat, St. Bertrand de Comminges Monrejeau or Montrejeau (pop. 1801 town, 2991 commune), and St. Martory, all on or near the Garonne; Bagnères de Luchon, described elsewhere [BAGNERES DE LUCHON], on the Pique; Aspet (pop. 5575 commune) and Soueich, on the Ger, a small affluent of the Garonne; Salies, on the Salat; Aurignac, near the Lougé; St. Blancard and Ile-en-Dodon, on the Save; Puymorin, on the Gesse, a feeder of the Save; and Boulogne (pop. 1505 town, 1587 commune), on the Gimone, which flows into the Garonne through the departments of Gers and Tarn et Garonne. St. Gaudens is the centre of a considerable trade with Spain. Some woollen cloth is manufactured, also tapes, hats, hosiery, leather, and paper. There are a high school and an agricultural society. This town was the capital of Nebouzan. St. Bertrand de Comminges, capital of Haut or Upper Comminges, is nearly on the site of a Roman town mentioned by Strabo and Ptolemy, under the name of Lugdunum Convenarum. This town was destroyed A.D. 585 by Gontran, king of the Burgundians. It was rebuilt early in the 12th century by Atton Raimond, lord of Ile Jourdain, and St. Bertrand, bishop of Comminges, from the latter of whom it took its name. There are many remains of Lugdunum, but principally out of the present town (which is very small, having a population under 1000), at the foot of the hill on which it is situated. The seat of the bishopric of Haut Comminges, established in the 6th century, was fixed here.

The population of the towns is (when not otherwise mentioned) from the cenus of 1831.

The department is comprehended in the tenth military division, of which the head-quarters are at Toulouse. It constitutes the metropolitan diocese of Toulouse; and is comprehended in the jurisdiction of the Cour Royale, and the circuit of the Académie Universitaire of that city. It sends six members to the Chamber of Deputies.

GARRICK, DAVID, descended from a French Protestant family of the name of Garric, or Garrique, was born on the 20th of February, 1716, at the Angel Inn, Hereford. His father was Captain Peter Garrick, of the Old Buffs, then recruiting in that city, and his mother, whose maiden name was Arabella Clough, was the daughter of one of the vicars of Lichfield Cathedral. David was baptized on the 28th of February, according to the register of the church of All Saints, Hereford. At ten years of age he was placed under the care of Mr. Hunter, master of the grammar-school at Lichfield; and in 1727 showed his predilection for the stage by performing Serjeant Kite, in Farquhar's comedy of the 'Recruiting Officer.' Shortly afterwards he went to Lisbon on a visit to his uncle, a wine-merchant there, and by his agreeable manners became a great favourite not only with the English residents, but amongst the young Portuguese nobility. In the following year he returned to his school at Lichfield, and during occasional visits to London encouraged his growing passion for theatricals. In 1735 he became the pupil of Dr. (then Mr.) Samuel Johnson, with whom, on the 2nd of March, 1736, he set out for the metropolis, and on the 9th of the same month entered himself in the Society of Lincoln's Inn. In 1737 he commenced a course of studies under Mr. Colson, the mathematician, at Rochester. Shortly afterwards, on the death of his father, he commenced business as a wine-merchant, in partnership with his elder brother, Peter Garrick. This partnership was however soon dissolved, and in 1741 David Garrick finally resolved upon the profession of the stage, and made his first appearance at Ipswich under the name of Lyddal, and in the part of Aboan, in the tragedy of 'Oroonoko.' His success was undoubted, and he soon became a great favourite in that town, playing not only tragedy and comedy, but exhibiting his grace, humour, and agility as harlequin. In the autumn he returned to London with the manager of the Ipswich company, who was also proprietor of the theatre in Goodman's Fields: and on the boards of that establishment Mr. Garrick made his first appearance as Richard III., October 19th, 1741. The fame of the young actor, then only in his twenty-sixth year, spread in a few weeks throughout the metropolis; and from the time of his first benefit, December 2nd, on which occasion he performed Lothario, in the 'The Fair Penitent,' persons of every condition flocked from all parts of the town to see him, and entirely deserted the theatres at the West-end. At the close of the season, May 26, 1742, Mr. Garrick played three nights at Drury Lane theatre, as Bayes, Lear, and Richard, and then set off for Dublin, accompanied by Mrs. Woffington. In Ireland he sustained his reputation, and the theatre was crowded to such a degree as, in conjunction with the heat of the weather, to produce an epidemic, which was called *the Garrick fever*. He returned to London for the winter season, and commenced an engagement at Drury Lane on the 5th of October, as Chamont, in Otway's tragedy of 'The Orphan.' In 1745 he again visited Dublin, and became joint manager with Mr. Sheridan, of the Theatre Royal in Smock Alley. In 1746 he returned to England, and was engaged for the season by Mr. Rich, the patentee of Covent Garden theatre, on the close of which he purchased, in conjunction with Mr. Lacy, the Theatre Royal, Drury Lane (Mr. Fleetwood's patent having expired), and opened it on the 15th of September, 1747, with the play of 'The Merchant of Venice,' to which he spoke the well-known prologue written by Dr. Johnson.

On the 22nd of June, 1749, Mr. Garrick married Eva-Maria Violette (not Violetti, as generally written), the daughter of a respectable citizen of Vienna, who having been educated as a dancer, had made her first appearance at Drury Lane on the 3rd of December, 1746. Her real family name was Veigel, which in the Viennese patois signifies Violet, and she assumed the name of Violette by command of the empress Maria Theresa. Mr. and Mrs. Garrick were married first by Mr. Francklin, at his chapel near Russell Street, Bloomsbury, and afterwards, on the same day, by the Rev. Mr. Blythe, at the chapel of the Portuguese embassy, in South Audley Street, according to the rites of the Roman Catholic church.

On the 7th of September, 1769, Garrick put into execution his favourite scheme of the Jubilee in honour of Shakspeare, at Stratford-upon-Avon, and produced a pageant on the subject at Drury Lane in the following October. On the 10th of June, 1776, having managed Drury Lane theatre for twenty-nine years (with the exception of two passed abroad, 1763 and 1764), Garrick took his leave of the stage in the character of Don Felix, in 'The Wonder,' the performances being for the benefit of the fund for decayed actors. In 1777 Mr. Garrick was honoured by the command of their Majesties King George III. and Queen Charlotte to read a play at Buckingham House. He selected his own farce of 'Lethe,' introducing for the occasion the character of an ungrateful Jew, but having been so long accustomed to the thunders of applause in a theatre, the refined approbation of the Royal party threw, to use his

own expression, 'a wet blanket' over him. In the same year he was put into the commission of the peace.

At Christmas, 1778, while on a visit to Lord Spencer, at Althorpe, he had a severe fit, from which he only recovered sufficiently to enable him to return to town, and expired January 20th, 1779, at his own house in the Adelphi, having nearly completed his 63rd year. He was buried with great pomp in Westminster Abbey on the 1st of February.

As an actor Mr. Garrick's merits may be considered as summed up in the forcible words of Pope to lord Orrery on witnessing the performance of Richard—'That young man never had his equal as an actor, and will never have a rival.' As yet the prophecy is unshaken. Garrick was an excellent husband, a kind master, and a matchless companion. The charge of avarice so frequently made against him is disproved by a careful examination of his life. His latest biographer justly says, 'He loved affluence for its independence, and the power it bestowed of obliging the great and relieving the humble.' He was one of the most accomplished men of his day, and although his literary reputation is merged in the splendour of his histrionic fame, his rank as a writer of prologues and epilogues, and in the lighter kinds of verse, must be generally acknowledged as considerable. His alterations and adaptations of popular English and French plays were numerous and successful, and with the addition of his original contributions to the drama, exceed forty. The best known to the present generation of play-goers is the farce of 'The Lying Valet,' and the comedy of 'The Clandestine Marriage,' of which latter he was joint author with the elder Colman.

Mrs. Garrick survived her husband forty-three years, and expired suddenly in her chair after a short indisposition, at her house in the Adelphi, on the 16th of October, 1822, in the ninety-eighth year of her age, having retained her faculties to the last. She was buried October 25th, in the same grave with her husband, near the cenotaph of Shakspeare.

Garrick's private correspondence, with a new biographical memoir, was published in two volumes, 4to., London, 1831.

GARROW HILLS. [HINDUSTAN.]

GA'RRULUS. [CORVIDÆ, vol. viii., p. 69.]

GARRYA'CEÆ, a very small natural order of Exogens with the habit of a Viburnum and apetalous unisexual flowers, succeeded by succulent fruit, disposed in catkin-like racemes. One species only is known, the Garrya elliptica, figured and described in the 'Botanical Register,' vol. 20, plate 1686.

GARTER, ORDER OF THE, one of the most ancient and illustrious of the military orders of knighthood in Europe, was founded by King Edward III. The precise year of its institution has been disputed, though all authorities agree that it was established at Windsor after the celebration of a tournament. Walsingham and Fabyan give 1344 as its date; Stowe, who, according to Ashmole, is corroborated by the statutes of the Order says 1350. The precise cause of the origin or formation of the Order is likewise not distinctly known. The common story respecting the fall of the Countess of Salisbury's garter at a ball, which was picked up by the king, and his retort to those who smiled at the action, *Honi soit qui mal y pense*, which afterwards became the motto of the order, is not entirely given up as fable. A tradition certainly obtained as far back as the time of Henry VI. that this Order received its origin from the fair sex. Ashmole's opinion was, that the Garter was selected at once as a symbol of union and a compliment to the ladies.

This Order was founded in honour of the Holy Trinity, the Virgin Mary, St. George, and St. Edward the Confessor. St. George, who had become the tutelary saint of England, was considered as its especial patron and protector. It was originally composed of twenty-five knights, and the sovereign (who nominates the other knights), twenty-six in all. This number received no alteration till the reign of George III., when it was directed that princes of the royal family and illustrious foreigners on whom the honour might be conferred should not be included. The number of these extra-knights was fourteen in 1834. The military knights of Windsor are also considered as an adjunct of the Order of the Garter.

The officers of the Order are a prelate, who is always the bishop of Winchester: a chancellor, who till 1837 was the bishop of Salisbury, but is now the bishop of Oxford, in consequence of Berkshire, and of course Windsor, being transferred to that diocese; a registrar, who is the dean of Windsor; garter principal king-at-arms of the Order; and a gentleman usher of the black rod. The chapter ought to meet every year on St. George's day (April 23rd), in St. George's chapel, Windsor, where the installations of the Order are held, and in which the banners of the several knights are suspended.

The original dress of the Knights of the Garter was a mantle, tunic, and capuchin or hood, of the fashion of the time, all of blue cloth; those of the knights companions differing only from the sovereign's by the tunic being lined with miniver instead of ermine. All the three garments were embroidered with garters of blue and gold, the mantle having one larger than all the rest on the left shoulder. The dress underwent various changes. Henry VIII. remodelled both it and the statutes of the Order, and gave the knights the collar, and the greater and lesser George, as at present worn. The last alteration in the dress took place in the reign of Charles II.: the principal parts of it consist of a mantle of dark blue velvet, with a hood of crimson velvet; a cap or hat with an ostrich and heron plume; the stockings are of white silk, and the garter, which is of dark blue velvet, having the motto embroidered in gold letters, is worn under the left knee. The badge is a gold medallion representing St. George and the dragon, which is worn suspended by a blue ribbon; hence it is a form of speech to say, when an individual has been appointed a knight of the garter, that he has received the blue ribbon. There is also a star worn on the left breast. The fashion of wearing the blue ribbon suspended from the left shoulder was adopted in the latter part of the reign of Charles II.

It is not generally known, that from the first institution of the Order of the Garter to at least as late as the reign of Edward IV., ladies were admitted to a participation in the honours of the fraternity. The queen, some of the knights-companions' wives, and other great ladies, had robes and hoods of the gift of the sovereign, the former garnished with little embroidered garters. The ensign of the garter was also delivered to them, and they were expressly termed *Dames de la fraternité de St. George*. The splendid appearance of Queen Philippa at the first grand feast of the Order is noticed by Froissart. Two monuments also are still existing which bear figures of ladies wearing the garter: the Duchess of Suffolk's, at Ewelme, in Oxfordshire, of the time of Henry VI., represents her wearing it on the wrist, in the manner of a bracelet; Lady Harcourt, at Stanton Harcourt, in Oxfordshire, of the time of Edward IV., wears the garter on her left arm.

Ashmole, writing on the habit and ensigns of the Order (*Hist. of the Order of the Garter*, fol. Lond. 1672, p. 218), says, 'After a long disuse of these robes by the queens of England and knights-companions' ladies, there was at the feast of St. George, celebrated an. 14 Cha. I., endeavour used to have them restored; for the then deputy-chancellor moved the sovereign in chapter (held the 22nd May), that the ladies of the knights-companions might have the privilege to wear a garter of the Order about their arms, and an upper robe, at festival times, according to ancient usage. Upon which motion the sovereign gave order that the queen should be acquainted therewith and her pleasure known, and the affair left to the ladies' particular suit. The 10th of October in the following year (1639), the feast of St. George being then also kept at Windsor, the deputy-chancellor reported to the sovereign in chapter the answer which the queen was pleased to give him to the aforesaid order, whereupon it was then left to a chapter to be called by the knights-companions to consider of every circumstance, how it were fittest to be done for the honour of the Order, which was appointed to be held at London about Alhollantide after; but what was then or after done doth not appear; and the unhappy war coming on, this matter wholly slept.'

When Queen Anne attended the thanksgiving at St. Paul's in 1702, and again in 1704, she wore the garter set with diamonds, as sovereign of the Order, tied round her left arm.

GARTH, SAMUEL, eminent as a physician and a wit, during the reigns of William III. and Anne, was descended of a good Yorkshire family, received his academical education at Peterhouse, Cambridge, and graduated as M.D. in 1691. Having settled in London, he rendered himself distinguished by his conversational powers, which recommended and set off his professional skill, and soon acquired

very extensive practice. Being a zealous Whig, he became intimate with the wits and great men of the Whig party. At the accession of the House of Hanover, he obtained his reward in the honour of knighthood, and in the offices of physician and ordinary to George I., and physician-general to the army. He died January 18, 1718.

Garth is known in our literary history as the author of a mock-heroic poem called 'The Dispensary.' It arose out of a quarrel between the College of Physicians and the Corporation of Apothecaries, concerning the establishment of a (then) new charity, for the gratuitous distribution of advice and medicine to the poor. To this the apothecaries strongly objected, as being injurious to their business. Garth, a strong supporter of the dispensary, wrote his poem to satirise its opponents, and recommend the scheme to the public. It is written with a competent share of spirit and elegance, and obtained popularity. But the introduction of the supernatural machinery of the antient epic, and the imitation of Homer's battle-scenes, are so extravagant and incongruous when pressed into the account of a medical squabble of the seventeenth century, that a poem of near 2000 lines, of which they form the staple, could not be expected to keep its ground when the temporary interest of its subject passed away. Accordingly it has long ceased to find readers. Garth's other original poems consist of occasional pieces, prologues, epilogues, and the like. He superintended a translation of Ovid's 'Metamorphoses,' by various hands; among whom were an unusual number of eminent men. Dryden contributed the first, twelfth, and many portions of other books. Addison, the second and third. Gay, Pope, Congreve, Rowe, and other less distinguished men were also concerned. Garth himself contributed the fourteenth, and part of the fifteenth book, with a critical preface, slightingly noticed by Dr. Johnson. (*Lives of the Poets: Prefaces, Dispensary*, and *Ovid; Biogr. Brit.*)

GARVE, CHRISTIAN, was born at Breslau in the year 1742. At an early age he lost his father, and he was indebted for his education to the solicitude of his mother. He attended the gymnasium at Breslau, and was designed for the church, which however, on account of the delicate state of his health, he never entered. In 1760 he attended the high school at Halle for the purpose of studying mathematics and philosophy, which studies he continued to pursue at the university of Leipzig, when Gellert, Weisse, and others were his friends. He returned to his mother's house at Breslau in 1767, and studied so hard as to injure his naturally weak constitution, and to bring on a hypochondriacal temperament. On the death of Gellert in 1769, Garve was called to Leipzig to fill the vacant professorship, and he read lectures on pure mathematics and logic as long as his declining health would allow, till at last he was obliged to resign his office and return to his native town, where he was a private teacher for nearly the remainder of his life. A translation of Burke 'On the Sublime and Beautiful,' and of other English works, first made him known to the literary world; and his 'Philosophical Treatises' (*Philosophische Abhandlungen*), published in 1779, gained him such reputation that Frederick the Great invited him to Charlottenburg and treated him with marked respect. At the suggestion of the king he published an edition of Cicero's 'Offices,' which appeared in 1783, and went through four editions. Garve's last years were passed in great misery. He bore his sufferings with the most exemplary fortitude, and died in 1798.

Garve is one of those writers who were called philosophers before German philosophy had assumed that peculiar character which it bears at present. His treatises are in a popular style, and are on subjects of general and practical interest, such as 'patience under calamity,' 'the advantages of a moral life,' and so on. The last century abounded with writers of this description, many of whom were little more than verbose enunciators of common-places. But Garve was not of this class. Though he does not discuss abstruse matters, nor leave the sphere of practical usefulness, he often considers his subjects in a new light, and starts points which would never have struck an ordinary mind. In one instance he mentions the much-decried Spinoza with tolerable respect, which shows him to have been above the prejudices of a time when it was fashionable to speak of this philosopher in terms of the greatest abhorrence without knowing any one of his opinions. Garve translated the 'Politik,' 'Ethics,' and 'Rhetoric' of Aristotle into German; these translations, though not without their merits, by no means present a faithful counterpart of the originals.

GAS, a term employed by chemists as synonymous with air. It was first used in a very general sense by Van Helmont; but in consequence of the great number of permanently-elastic fluids discovered by Priestley, so different in their properties from common air, and in order to avoid any confusion from the use of the same word to express both, Macquer employed the term gas, which has been universally adopted to distinguish from mere vapours all such elastic fluids as had not been rendered liquid or solid by reducing their temperature.

The experiments of Professor Faraday have however shown that elastic fluids are included in this definition, which may be liquefied by reducing the temperature and increasing the pressure. Still however there exists this difference between bodies in the elastic state: - vapours generated by the agency of heat are reduced to solids or liquids when the heat is withdrawn; while gases preserve their aëriform state at common temperatures. It must however be admitted that the difference is one of degree only, and though not an essential one, it is usefully retained.

Every gas consists of the ponderable matter from which its name is derived, combined with that degree of specific heat which is necessary to its aëriform existence.

The number of gaseous bodies is great, and they possess in many respects such different properties, that it would be impossible to give a general description of them. The qualities therefore peculiar to each gas will be stated under its proper head: thus it will appear that some gases are elementary or simple in their nature, while by far the greater number are compound bodies; few of them exist in nature, but are mostly the products of chemical agency. Gases differ as to colour, odour, taste, specific gravity, and solubility in water; they vary also in their effects upon the animal economy, and in their relations to heat: most of them are either combustible or supporters of combustion, but one important gas at least belongs to neither class. Their powers of chemical combination are also extremely different; one gas only possesses alkaline properties, whilst there are several gaseous acids.

One most important circumstance relative to gaseous bodies has been much discussed, and very opposite conclusions have been arrived at respecting it by philosophers of eminence: it is this, whether all gases, under the same volume and pressure, have the same specific heat. That this is the case, has been maintained by Haycraft, and Marcet and Delarive, and some others; while Dalton, Delaroche and Berard, Dulong and Dr. Apjohn, &c., are of opinion that equal volumes of different gases have not the same specific heat under similar circumstances.

It would be useless to detail the processes or to describe the apparatus by which chemists have arrived at such discordant results. The experiments of Delaroche and Berard, which are in general most relied upon, though complicated, were made with great care: they transmitted known quantities of gas, heated to 212° in a uniform current, through a calorimeter, the serpentine of which was surrounded with water, the temperature of which, as well as of the gas at its exit, being ascertained during the course of the process by very delicate thermometers. These chemists operated with a considerable quantity of gas, and used other precautions to avoid the errors into which other experimentalists had fallen.

The following is a statement of the results obtained by Dalaroche and Berard, Dulong, and Dr. Apjohn, of the specific heats of equal volumes of the gases mentioned, under equal pressures:—

	Delaroche and Berard.	Dulong.	Apjohn.
Atmospheric air . .	1·000	1·000	1·000
Azote	1·000	1·000	1·048
Oxygen	·976	1·000	·808
Hydrogen . . .	·903	1·300	1·459
Carbonic acid . .	1·258	1·172	1·195
Carbonic oxide . .	1·034	1·000	·996
Nitrous oxide . .	1·350	1·159	1·193

Dr. Apjohn observes that the numbers which he has arrived at correspond tolerably well with those of Delaroche and Berard, except in the case of hydrogen; and he admits that he does not speak with much confidence of the numbers attached to azote and oxygen.

There are some other properties which gases possess in common, though they vary in degree. There is however one circumstance in which they all agree, whether they are elementary or compound, and whatever may be the difference of their specific gravity:—they are subject to suffer the same increase of volume, when subjected to the same increase of temperature.

According to Dalton, when 100 volumes of air are heated from 32° to 212°, they become 132·5 volumes; by Gay-Lussac's experiments they increase to 137·5 volumes; by Crichton's to 137·48: the expansion therefore of each volume, according to Dalton is $\frac{1}{556}$, to Gay-Lussac $\frac{1}{480}$, and to Crichton $\frac{1}{480 \cdot 23}$, for one degree of Fahrenheit's thermometer.

The discovery of this law has supplied chemists with a simple rule for determining what the known bulk of a gas at any temperature will be at any other temperature. Suppose, for example, it is desired to know what the bulk of 100 cubic inches of air at 32° will be at 60°: subtract 32 from 480, the remainder is 448; to which add the degrees above zero indicating the temperature of the air, these are 32° and 60°, making 480 and 508. Then say 480 : 508 : : 100 : 105·832, the volume of the air at 60°.

It is well known that air suffers diminution of volume in proportion to the pressure to which it is subjected, and the same law holds good with all the more incondensible gases. In chemical analyses it is often requisite to make corrections for variations of barometric pressure, as well as of temperature in estimating the quantity of gaseous products. The following are the rules for this purpose, given by Professor Faraday in his work on Chemical Manipulation :—'A pressure of 30 inches of mercury, as observed by an accurate barometer, has been assumed as the *mean height* or *barometric pressure*, and volumes of gas observed at any other pressure frequently require to be corrected to what they would be at this point. For this purpose it is only necessary to compare the observed height with the mean height, or 30 inches, and increase or diminish the observed volume inversely in the same proportion. Thus, as the mean height of the barometer is to the observed height, so is the observed volume to the volume required. As an instance, suppose that 100 cubic inches of gas have been observed when the barometer stood at 30·7 inches: then, as 30 inches, or mean height, is to 30·7 inches, or observed height, so is 100, or the observed volume to a fourth proportional, obtained by multiplying the second and third terms, and dividing by the first: thus, 30·7 × 100 = 3070, which divided by 30 = 102·333 cubic inches; this would be the volume of the gas at 30 inches of barometric pressure. Again, suppose a quantity of gas amounting to 20 cubic inches standing over mercury in a jar, the level of the metal within being 3 inches above that without, and the barometer at 29·4 inches. Then the column of 3 inches mercury within the jar, counterbalancing 3 inches of barometric pressure, instead of being 29·4, the latter is effectively only 26·4, and the correction will be, as 30 inches is to 26·4 inches, so is the 20 cubic inches observed to 17·6 cubic inches, the volume which the gas would really occupy if the mercury were level within and without the jar, and the barometer were 30 inches.'

It is very commonly requisite to make corrections both for temperature and pressure in the same volume of gas, and it is of no consequence which is made first.

In chemical analyses various other considerations arise in ascertaining the quantities of gaseous products; as for example, the separation of or making the requisite allowances for the moisture which they contain: for these, as well as for the various modes of collecting, transferring, and preserving various gases, we must refer to the very excellent work just quoted.

The solubility of gases in water is extremely various. Dr. Henry ascertained that the volume of each gas absorbed by water is the same, whatever be the pressure to which the gas is previously subjected. If the weight of carbonic acid gas be doubled by subjecting it to the pressure of two atmospheres, water will still absorb its own volume of it. The following table exhibits the volumes of each gas absorbed by 100 volumes of water, supposing the temperature and pressure to be the same in all cases:—

	Absorption in Volumes.	Authority.
Cyanogen	450	Gay-Lussac
Sulphuretted hydrogen	366·6	Thomson
Chlorine	200	Berthollet
Carbonic acid	106	Cavendish
Nitrous oxide	76	Saussure
Olefiant gas	15·3	Saussure
Phosphuretted hydrogen	5	Thomson
Nitric oxide	3·7	Dalton
Oxygen	3·7	Henry
Carburetted hydrogen	3·7	Dalton
Azote	2·5	Dalton
Carbonic oxide	2·01	Henry
Hydrogen	2	Dalton

It may be observed, that in general the more easily a gas is condensable by cold and pressure, the more soluble it is in water: this will appear by comparing the above statements with that containing the pressure at which Faraday liquefied various gases.

A curious property of gases, and possessed by them in very different degrees, is that of their condensation by porous bodies, and especially by charcoal. According to Saussure, one volume of charcoal, made red-hot, cooled under mercury, and exposed to the under-mentioned gases, absorbed the volumes annexed; the absorption was completed in twenty-four hours, and when the charcoal which had been saturated with one gas was removed to another, a portion of the first was expelled, and replaced by a portion of the second:—

Ammonia	90	Olefiant gas	35
Hydrochloric acid	85	Oxide of carbon	9·42
Sulphurous acid	65	Oxygen	9·25
Hydrosulphuric acid	55	Azote	7·50
Nitrous oxide	40	Carburetted hydrogen	5
Carbonic acid	35	Hydrogen	1·75

It is extremely probable that different kinds of charcoal absorb different portions of the same gas; for it was found by Messrs. Allen and Pepys, that they absorbed very different quantities, chiefly of moisture, by exposure to the air.

A curious fact with respect to mixtures of gases was discovered by Dr. Priestley, which he thus states:—'Different kinds of air that have no affinity do not, when mixed together, separate spontaneously, but continue diffused through each other.' This he proved to be the case by several experiments; and more especially by one, in which he found that he was able to explode hydrogen and oxygen gases, which had long remained together, and which he justly argues must have been mixed, or he could not have fired them by an electric spark, in a vessel, the wires of which were at the top. He adduces this experiment to illustrate the fact that the gases which constitute the atmosphere do not separate according to their respective gravities, though they do not combine. (Priestley's *Experiments*, &c., vol. vi. p. 391.)

These experiments were repeated by Dr. Dalton, and he inferred from them that the particles of one gas, though repulsive to each other, do not repel those of a different kind; and that one gas acts as a vacuum with respect to another. If therefore a vessel full of carbonic acid be made to communicate with another of hydrogen, the particles of each gas insinuate themselves between the particles of each other till they are equally diffused through both vessels. This theory accounts not only for the mixture of gases, but for the equable diffusion of vapours through gases and through each other.

Another observation made by Dr. Priestley, and related with others of a similar kind (*American Phil. Trans.* vol. v.), appears to have been entirely overlooked. He found that though a glass vessel was perfectly air-tight, yet if it had been broken, and the pieces joined with paint or cement, hydrogen gas contained in it would be changed for the external air. Döbereiner has since remarked the escape of hydrogen gas by a fissure or crack in glass receivers. Professor Graham, in an elaborate paper on this subject, has shown that gases diffuse into atmospheric air and into each other, with different degrees of ease and rapidity, the lighter ones escaping most readily, so much indeed, that hydrogen escapes five times more quickly than carbonic acid gas, which is about 22 times heavier.

To Dr. Priestley also we are indebted for the important discovery that gases can pass through membranes which are perfectly air-tight, and by this action he explained that of the atmosphere upon the blood in the lungs. In the memoir above alluded to he has also shown, that when a bladder containing hydrogen is put into a vessel of oxygen,

or one with oxygen into a vessel of hydrogen, the bladder and the vessel of gas both contain both gases, owing to the passage of the gases from and into the bladder. It is also stated by Professor Graham, that if a bladder, half filled with air, with its mouth tied, be passed up into a large jar filled with carbonic acid gas, standing over water, the bladder, in the course of twenty-four hours, becomes greatly distended by the insinuation of the carbonic acid through its substance, and may even burst, while a very little air escapes outwards from the bladder. This however he does not consider as a case of simple diffusion; the result depends, first, upon carbonic acid being a gas easily liquefied by the water in the substance of the membrane, and therefore the carbonic acid penetrates the membrane as a liquid; secondly, this liquid is in the highest degree volatile, and therefore evaporates very readily from the inner surface of the bladder into the air confined in it. The air in the bladder comes to be expanded in the same manner as if æther or any other volatile fluid was admitted into it. Professor Graham further observes, that in the experiments of Dr. Mitchell and Faust and others, in which gases passed through a sheet of caoutchouc, it is to be supposed that the gases were always liquefied in that substance, and penetrates through it in a fluid form; and it is also to be noticed, that it is always those gases which are more easily liquefied by cold or pressure that pass most readily through both caoutchouc and humid membranes.

Dr. Mitchell found that the time required for the passage of equal volumes of different gases through the same membrane was—

1	minute	with	ammonia.
2½	minutes	with	hydrosulphuric acid.
3½	„	„	cyanogen.
5½	„	„	carbonic acid.
6½	„	„	nitrous oxide.
27½	„	„	arseniuretted hydrogen.
28	„	„	olefiant gas.
37½	„	„	hydrogen.
113	„	„	oxygen.
160	„	„	carbonic oxide.
And with a much longer time		. .	azote.

It has been already observed, that the original definition of the term *gas* required modification on account of the condensation and liquefaction of some elastic fluids, by Professor Faraday, which had resisted all previous attempts. He subjected numerous gases to experiment, in order to determine how many of them could be rendered fluid by the combined agency of cold and pressure; and he succeeded with those which we shall presently enumerate: among them it may be remarked that chlorine is the only elementary gas which was liquefied. The ingredients for producing the gases to be operated upon were put into a strong glass tube, which was then hermetically sealed and slightly bent in the middle, so that one portion of the tube might serve as a retort and the other as a receiver. When requisite, the gas was generated by heat; and when the pressure of the atmosphere of gas formed was sufficiently great, the liquid formed and collected in the recipient end of the tube, which was kept cool to accelerate the condensation.

The following of the results obtained by Professor Faraday will show the different temperatures and pressures required to liquefy those gases which were condensed:—

Sulphurous acid gas . .	2	atmospheres	at	45°	Fahr.
Cyanogen gas	3·6	„	„	45	„
Chlorine gas	4·	„	„	60	„
Ammoniacal gas . . .	6·5	„	„	50	„
Hydrosulphuric acid gas	17·	„	„	50	„
Carbonic acid gas . .	36·	„	„	32	„
Hydrochloric acid gas .	40·	„	„	50	„
Nitrous oxide gas . . .	50·	„	„	45	„

No one of these gases was solidified, but within a short time Thilorier has succeeded in solidifying carbonic acid gas. He found that when the liquid acid was dropped, that owing to the conversion of one portion suddenly into gas, the remainder was so much cooled as to solidify.

It is to be observed, that although cold and pressure, as far as they have hitherto been tried, are incapable even of liquefying many of the gases, yet they may easily be even solidified by combination with each other in many cases, or by union with solid bodies.

Thus oxygen and hydrogen, which have never been separately even liquefied, form water by combination, which, as is well known, is rendered solid by a moderate reduction of temperature. Hydrogen and azote form ammoniacal gas, and hydrogen and chlorine constitute hydrochloric acid gas; these two compound gases combine without the application either of cold or pressure, and immediately form the well-known solid hydrochlorate of ammonia; yet it may be noticed that chlorine is the only one, of the three elementary gases which enter into the composition of the solid, that has ever been liquefied.

These remarks would admit of great extension, but they are sufficient to establish points for which they are adduced.

In concluding we may observe that gaseous bodies are of the highest importance in every possible respect, as connected not merely with the well-being, but as absolutely necessary to the existence of animals: two of them, oxygen and azote, form our atmosphere; two of them, hydrogen and oxygen, constitute water; oxygen united with various metals forms the greater part of the crust of our globe; and chlorine is one of the elements of common salt.

GAS LIGHTING.—*History*.—When coal, oil, wax, wood, or any other organic inflammable substance is exposed to destructive distillation in closed vessels, an inflammable gas is the result. This gas is some compound of hydrogen and carbon. The experiments of Dr. Henry show that those substances which give most light in burning, produce the most brilliantly illuminating gas when distilled. The following list, giving the proportion of oxygen required to consume a hundred measures of each gas, results from the experiments of Dr. Henry, who considers that the illuminating power of each is proportionate to the quantity of oxygen required to consume it:—

100 measures	of	hydrogen require	50	meas.	of oxygen.
„	„	dried peat gas	68	„	„
„	„	oak wood gas	54	„	„
„	„	cannel coal gas	170	„	„
„	„	lamp oil gas	190	„	„
„	„	wax gas	220	„	„
„	„	pure olefiant gas	284	„	„

The chemical nature of these gases is treated under HYDROGEN; our business at present is with coal gas as used for artificial light, and incidently with such other gases as have been employed or proposed for the same object.

The existence and inflammability of coal gas have been known for nearly 200 years. In the year 1659, Thomas Shirley correctly attributed the exhalations from the burning well of Wigan in Lancashire to the coal-beds which lie under that part of the county; and soon after Dr. Clayton, influenced by the reasoning of Shirley, actually made coal gas, and detailed the results of his labours in a letter to the Hon. Robert Boyle, who died in the year 1691. He says he distilled coal in a retort, and that the products were phlegm, black oil, and a spirit which he was unable to condense, but which he confined in a bladder. These are precisely what we now find, but under different names; the phlegm is water, the black oil is coal tar, and the spirit is gas. Dr. Clayton several times repeated the experiment, and frequently amused his friends with burning the gas as it came from the bladder through holes made in it with a pin. This was a hint which, in an age more alive to economic improvement, might have brought gas-lighting into operation a century earlier; though the mechanical difficulties might have been too great to overcome at that period; a circumstance which has retarded the introduction of many valuable discoveries, as it did that of the steam-boat and the printing-machine.

In the year 1733 Sir James Lowther communicated to the Royal Society a curious notice of a spontaneous evolution of gas at a colliery belonging to him near Whitehaven. While his men were at work, they were surprised by a rush of air, which caught fire at the approach of a candle, and burned with a flame two yards high and one yard in diameter; they were much frightened, but put the flame out by flapping it with their hats, and then all ran away. The steward of the works hearing this went down himself, lighted the air again, which had now increased, and had some difficulty in extinguishing it. It was found to annoy the workmen so much, that a tube was made to carry it off The tube projected four yards above the pit, and at the extremity of it the gas rushed out with much force. ' The gas

being fired,' says the account, 'it has now been burning two years and nine months, without any sign of decrease.' Large bladders were filled in a few seconds from the end of the tube, and carried away by persons, who fitted little pipes to them and burned the gas at their own convenience. We do not learn what became of this copious supply; it probably diminished as the coal-bed was exhausted.

Soon after the middle of the last century Dr. Watson made many experiments on coal gas, which he details in his 'Chemical Essays:' he distilled the coal, passed the gas through water, conveyed it through pipes from one place to another, and did so much that we are only surprised he did not introduce it into general use.

But although the properties of coal gas were known to so many persons, no one thought of applying it to a useful object until the year 1792, when Mr. Murdoch, an engineer, residing at Redruth in Cornwall, erected a little gasometer and apparatus, which produced gas enough to light his own house and offices. Mr. Murdoch appears to have had no imitators, but he was not discouraged, and in 1797 he erected a similar apparatus in Ayrshire, where he then resided. In the following year he was engaged to put up a gas-work at the manufactory of Boulton and Watt, at Soho. This was the first application of gas in the large way: but, excepting in manufactories or among scientific men, it excited little attention until the year 1802, when the front of the great Soho manufactory was brilliantly illuminated with it on the occasion of the public rejoicings at the peace. Accustomed as we are to the common use of gas, we cannot even now but be struck with such a display on a large scale: but the superiority of the new light over the dingy oil lamps used at that day, when thus brought into public view, produced an astonishing effect. All Birmingham poured forth to view the spectacle, and strangers carried to every part of the country an account of what they had seen. It was spread about everywhere by the newspapers, easy modes of making gas were described, and coal was distilled in tobacco-pipes at the fire-side all over the kingdom. Soon after this several manufacturers, whose works required light and heat, adopted the use of gas: a button manufactory at Birmingham used it largely for soldering: Halifax, Manchester, and other towns followed. A single cotton-mill in Manchester used above 900 burners, and had several miles of pipe laid down to supply them: the quantity made averaged 1250 cubic feet per hour, producing a light equal to that of 2500 candles. Mr. Murdoch, who erected the apparatus used in this mill, sent a detailed account of his operations to the Royal Society in 1808, for which he received their gold medal.

But although the use of gas was thus spreading in the manufacturing towns, it made little progress in London. This may be accounted for, in some measure, by the circumstance that no means had as yet been found out for purifying it. It was dirty, it had a disagreeable smell, and it caused headache when used in close rooms, besides spoiling delicate furniture. This was of little consequence in a manufactory, where there is generally ventilation enough to carry off unpleasant vapours, and rarely very delicate organs or fine furniture to suffer from their influence. But these defects were fatal to its general introduction in London, and until they could be removed there was small hope of success; though attempts were made, lectures delivered, and a number of interesting experiments made by a German named Winsor, whose perseverance and sanguine temper were very efficient in making the matter known to the public. But Winsor was deficient in chemical knowledge and mechanical skill, while he largely overrated the powers of the new instrument which he was zealously endeavouring to introduce. He took out a patent in 1804; and issued a flaming prospectus of a National Light and Heat Company, promising to subscribers of 5*l.* a fortune of at least 570*l.* per annum, with a prospect of ten times as much. A subscription was soon raised, it is said, of 50,000*l.* which was all expended in experiments without profit to the subscribers. Winsor however gained experience, and is said, we know not how truly, to have introduced the important measure of purifying gas by lime. In 1807 he lighted up Pall Mall, which continued for some years to be the only street in London in which gas was used. In 1809 the National Light and Heat Company applied to Parliament for a charter, but they were opposed by Mr. Murdoch on the score of prior discovery, and the charter was refused. It was however granted on a subsequent application, and the operations of the company became more extensive. But their profits had not yet begun, and increase of business was only increase of expense. The subscribers began to be alarmed at the exhaustion of their funds, and called loudly for a change in the management of their affairs. This was conceded, and the superintendence of their works was entrusted to Mr. Clegg, who had been for some years engaged in the erection of gas apparatus in Birmingham. Affairs now began to wear a better face; other parts of London applied for light, and new stations were erected. The business of the company steadily increased, and in the year 1823, in the course of a parliamentary investigation, it was shown that this company alone consumed annually 20,678 chaldrons of coals, which produced on an average 680,000 cubic feet of gas every night; this was distributed by means of 122 miles of pipe, which supplied more than 30,000 burners, giving a light equal to as many pounds of tallow candles. The other companies then established made altogether about the same quantity; and such has been the increase of gas-lighting since that time, that at one of their stations only, the chartered company are now making 1,200,000 cubic feet every twenty-four hours, and average about a million all the year round. We believe it may be asserted, that every street and alley in London is now lighted with gas, and the consumption of the metropolis may be stated at eight millions and a half of cubic feet every twenty-four hours.

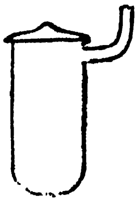
The great success which attended gas-light in London has extended itself throughout Great Britain. Every large town has long had gas; the smaller towns have followed, and there is now scarcely a place in the kingdom without it. The continental nations have slowly followed our example; Paris for some years, and more recently the towns of Lyon, Marseille, Bordeaux, Nantes, Caen, Boulogne, Amiens, and several others, have adopted it. It is in use in many parts of Germany and Belgium, and St. Petersburg has a small establishment, which is rapidly increasing under the superintendence of a gentleman from one of th London works. The larger towns in the United State also burn gas: and even in the remote colony of New South Wales, the town of Sydney has introduced this valuable invention, which we have no doubt will be found there, as it has been in London, as useful in preventing nocturnal outrage as an army of watchmen.

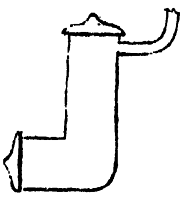
It will not be necessary to say much about oil gas: the light it produces is, it is true, much greater than that given out by an equal quantity of coal gas; but although it was introduced with success in some places where coal was dear, it has always yielded to coal wherever the two came into competition. The process of manufacture is exceedingly simple, and the machinery is much cheaper. But the cost of the oil itself is the great objection, and we fear it will be found insuperable. Oil gas was for some time rendered portable: it was forced into strong vessels with a power equal to 450 lbs. upon the square inch, and, thus confined, could be carried about and placed upon a table. As each vessel contained about thirty times as much compressed gas as it would hold in its natural state, one of the capacity of a quarter of a foot would give light for several hours But even such a size as this was very clumsy, and the process seems to be declining.

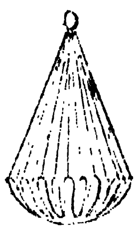
Some other substances have been proposed for gas-making, such as rosin, wood, and peat. Rosin has been tried at more than one establishment, but it has not been found to produce a gas much better than coal gas, while the cost is much greater. An American, some years ago, took out a patent for making gas from cotton seeds, which are, it appears, of very little value in America; but whether or not he has reaped any advantage from the suggestion, we are not informed. The superior cheapness of coal, in those places where it can be procured, will probably always put it above any other material that could be proposed for the manufacture of gas.

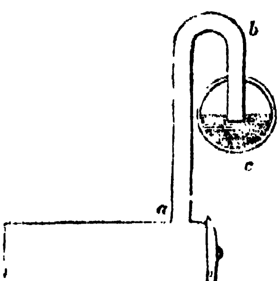
Manufacture.—Although in the large way there are many practical difficulties to be surmounted in the manufacture of coal gas, the operation is easily understood; it is merely a process of distillation. A quantity of coal is put into a retort, which is well closed, and placed upon the fire; the temperature is raised to redness, which decomposes the coal, and drives the gas resulting from the decomposition through a pipe leading from the retort to the receptacle prepared for it. A mass of coke remains, of greater bulk, though less weight, than the coal first put in. This coke must be taken

out, and replaced by a fresh supply of coal, and the process is to be repeated as often as may be requisite. Such is the theory of gas-making; the manner of putting it to practice remains to be described. The first part of the apparatus is the retort, which is made of cast-iron; the shape of this vessel has been somewhat altered from that which it first had. The original form is shown in this figure; it held about 15 lbs., and was placed in an upright position for the convenience of throwing in the coals; it was found to answer perfectly well; and so far as making gas is concerned, it could not be much improved. But the removal of the coke after the gas was made was found to be troublesome. Different means were devised to remedy the defect, one of which was to have an aperture near the bottom of the retort, at which the coke might be raked out, in addition to the one at the top where the coal was put in, as in this figure. This remedied the defect; but the trouble of stopping the retort, which is a work of some time, was thus doubled, and the probability of an escape of gas was much increased: the plan was consequently abandoned. Afterwards a much larger retort was adopted, shaped as the first, but holding about fifteen hundred-weight of coal, which would of course require feeding but rarely, and was emptied by a sort of grated iron or basket, called a grappler, suspended by chains. The grappler was put into the retort when empty, and was drawn out by a crane when the distillation was over. It was found however that the heat of the fire would not readily penetrate to the interior of such a large mass of coal; the outer portion formed a cake of nonconducting matter which protected the remaining coal, and caused the expenditure of much fuel. The gas was injured in its illuminating power by being formed so slowly, being deprived of its bituminous admixture by the continued heat. It was consequently found expedient to revert after all to the smaller-sized retort, and to lessen the inconvenience of taking out the coke it was placed in an horizontal position; the difficulty of filling a retort in this position was obviated by the use of a scoop or semicylindrical shovel long enough to reach to the end of it. This form of retort, which is still in common use, differs in different establishments only as one is a little larger or smaller than another, or more or less flattened, so as to expose a larger surface to the fire than would be the case with a true cylinder. The retorts are placed in ovens, in groups of three, five, seven, or more, according to the size of the establishments; and their mouths, where the coal is put in, stand out in front of the ovens. Just behind the mouth of the retort a pipe *a* leads from it perpendicularly upwards several feet; then taking a sudden turn, *b*, it descends again about a yard, and enters a much larger pipe *c*, technically called the hydraulic main, which runs through the whole building, and receives the gas produced from all the retorts. This great main is generally about half full of the tar and water which leave the coal with the heated gas, and rise with it in the state of vapour, but are condensed by the coldness of the main. Into this mixture the end of the pipe dips, and is thus closed against a return of gas, which would take place if the supply should slacken. A section of the ascending pipe and hydraulic main half full of liquid is shown in the figure.

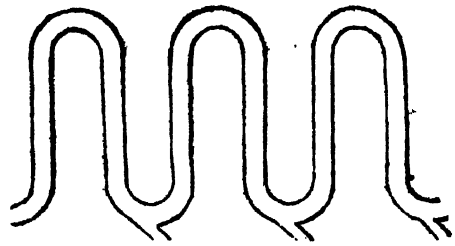






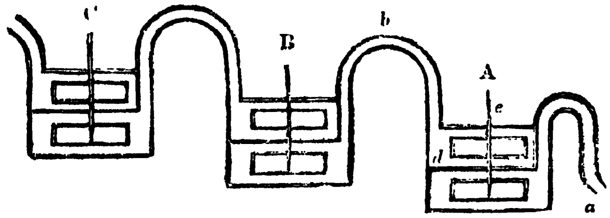


The gas is now made; but it is very impure, being mixed with water, tar, sulphuretted hydrogen gas, and other impurities. The tar and water are easily got rid of, little more being required for this purpose than to cool the gas and to allow the deposit to run off. This is effected by forcing it through a tube which is bent, as in the figure,



and which is kept cool by being immersed in cold water; or still better, as lately adopted in the principal establishment in London, by allowing cold water to drop upon it this last method has been found to lower the temperature from 20 to 25 degrees more than the old way.

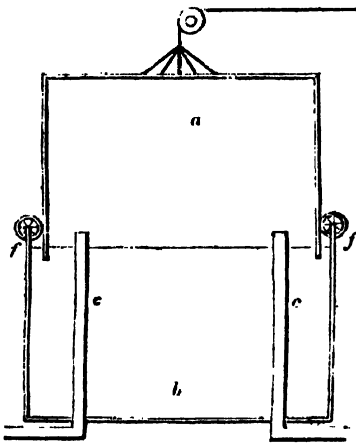
The separation of the sulphuretted hydrogen gas is a much more troublesome process: it cannot be got away by any washing or cooling, but passes through these processes without change. Worse than the other impurities mentioned, which are only offensive from dirt, this gas is a poison; in any considerable quantity it proves fatal, and is always very unwholesome. It can only be separated by some substance for which it has a chemical attraction, but which has no influence on coal gas. Such a substance is lime. Lime was suggested as a purifier by Dr. Henry, of Manchester, as early as the year 1808, though it was not used on a large scale until some years later; while a variety of inefficacious plans, such as passing the gas through hot iron tubes, and washing it with water, were often tried. The lime is used by being mixed up with water into a thin pasty mass, which the workmen call cream. The cream is placed in a cylindrical vessel, and is constantly stirred by an instrument called an agitator, which is an upright shaft with large flat pieces of wood or metal standing out perpendicularly from it, not unlike a chocolate-mill: the agitator is kept constantly revolving on its shaft, while the flat leaves pass through the whole mass of cream, keeping it well mixed. The gas as it comes from the condenser passes into the lime, and comes from it partially purified: it then enters another purifier, made and furnished precisely in a similar way: after that another: and often a fourth in large works. When it leaves the last vessel it may be considered pure. The accompanying figure will give an idea of the



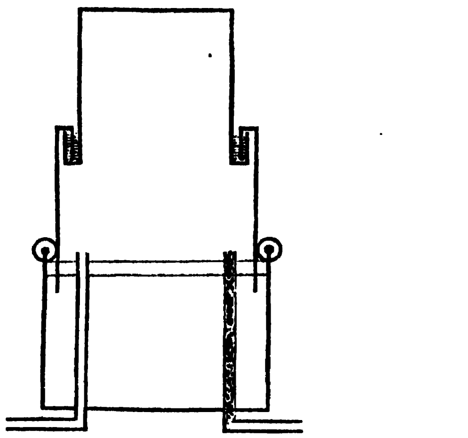
manner of arranging the purifiers. They are not all upon the same level; but the one marked C is higher than the middle one, marked B, and the lowest is A. This arrangement is made in order that the filling of the vessels may be accomplished with as little labour as practicable. The lime is mixed with water in a vessel placed above C, into which it descends by a pipe not in the figure; from C it is taken to B, and from B to A. The gas goes in the opposite direction: it enters the vessel A by the tube *a*, and is conveyed under the partition *d*, through which it passes by little holes into the upper division; it then passes through *b* into B, and then to C, from whence it comes out pure. The agitator is marked *e*. It will be understood that by this arrangement the fresh-made gas first meets a mixture which is deteriorated by having already purified a portion of gas in the higher vessels; it goes from that vessel into one filled with a more active agent; and then, almost pure, it goes into a mixture fresh from the reservoir, if there are but three purifiers in the set; but if there are four, it passes into a third before arriving at that one which contains the fresh mixture. In order to know whether or not the gas be pure, it is tested by a solution of acetate of lead, which is a colourless liquid. It is a property of sulphuretted hydrogen gas to produce a brown precipitate with any salt of lead; if therefore any of this gas be mixed with the coal gas which is placed in contact with the colourless solution, it will show itself by turning the liquid brown. The most usual way of testing is to open a stop-cock fixed for that purpose in some part of the pipe which leads the gas into

the last purifying vessel, and to put a card dipped in the solution in front of the small stream of gas which then issues out. If 1-20,000th part only of the bulk of gas should be sulphuretted hydrogen, it will produce a brown spot on the card; and as the whole of the gas, after undergoing this scrutiny, passes through the last purifier, it may now be considered quite pure. When the card shows any impurity, the fresh cream is admitted more freely, and the spoiled lime drawn away from the lowest vessel. This stuff, which has a nauseous smell, used to be allowed to run to waste, to the great annoyance of the public; but it is now usually dried, and employed as cement to lute the covers to the retorts.

In the *manufacture of oil gas* all the processes of filling and emptying retorts, condensing, and purifying, are avoided. It is only necessary to project a small stream of oil into a red-hot retort, in which pieces of brick or coke are inclosed; the gas immediately passes off through another pipe, and may be at once received into the gasometer. The only purification necessary, if it can be called so, is to allow the gas to pass through some cool vessel, which may receive any undecomposed oil that may have been carried off, to prevent its being wasted in the gasometer.



The gasometer *a* is a very large cylindrical vessel from 30 to 60 feet in diameter, closed at the top and open at bottom; it is suspended by a rope and weight *e* in a tank filled with water, in which it rises and falls freely, being kept in its place by the guide-wheels *f f*. Two tubes *c c* pass under and through the water, reaching above its surface into the hollow of the gasometer: one of them comes from the purifiers to admit the gas into the gasometer, the other carries it off when wanted for use. The action of this part of the apparatus is simple; in the figure the gasometer is near the top of the water, and full of gas, which has no communication with the air, because the edge of the gasometer is under water. If now it be pressed downwards, which is effected by lessening the weight *e*, the gas will be forced through the pipe which is to convey the gas out, and which must be left open for the purpose. When the gasometer reaches the bottom it will be full of water, and ready to receive gas again, which is admitted through the other tube; the gasometer then rises to the top as the gas goes in, and may be pressed down again. In this way it is alternately filled and emptied. In most establishments there are many gasometers, some filling, and others emptying. As it is a most unwieldy part of the apparatus, and takes up an enormous deal of room, many attempts have been made to lessen its bulk. The only contrivance which has succeeded in diminishing the inconvenience is termed the *telescope gasometer*, which has recently been adopted in several of the metropolitan establishments. In this plan, two gasometers, one inside the other, are placed in a single tank; they are shown in the figure as when drawn up and full of gas, but without any of the necessary appendages. When the gas is let in, the smaller gasometer rises first, and when it reaches the top of the water, its lower rim, which is turned up, and full of water, catches the upper rim of the larger gasometer, which is turned down over it; the two then become one, and the water which runs round the rim prevents the gas from getting out between them. This gasometer is not in reality less bulky than the old one, but as the increased space it takes up is in height, and not breadth, nearly one half of the area is saved; and there seems to be no reason



why three or more cylinders should not be placed in one tank in a similar way.

Many other contrivances are used before the gas is carried to its destination: a meter, to measure it; a governor, to equalize the flow; a pressure-gauge, to indicate the resistance offered to its passage; a tell-tale, to show the quantity manufactured during every hour: but the description of these would exceed our limits.

The tubes which convey the gas are of course larger or smaller according to the number of burners which they supply. The largest in use are about eighteen inches in diameter, the smallest about a quarter of an inch. A pipe of one inch in diameter is large enough to supply gas producing a light equal to that of 100 mould candles, each consuming 175 grains of tallow per hour; and the quantity supplied by larger tubes is more than proportionably larger, a four-inch pipe equalling 2000 candles, instead of 1600. This augmentation arises from the diminished friction in large tubes. In laying the pipes care is taken to place them sufficiently deep under the surface of the ground to be safe from injury by carriages rolling over, and they are disposed in straight lines so far as is practicable. They are also laid in slightly inclined planes, and a vessel is placed at the bottom of each descent to receive and carry off any deposition which would otherwise clog the pipes. They are cast with a socket at one end, in which the smaller end of the adjoining pipe is inserted, and the two are joined by running lead between the joints, which is driven in hard by a punch.

The burners are of many different forms, and each has its technical name. The argand burner is like the lamp of that name. The fan is a spreading semicircle of small jets. The cock-spur, a head with three jets only. The batswing is a thin sheet of gas produced by its passing through a fine saw-cut in a hollow globe. The argand and the batswing are said to give the best light with a given quantity of gas, but this seems to be very uncertain.

The gas is turned off from the burners by a stop-cock, and some curious inventions have been produced to make the stop-cock close of itself by the cooling of the burner when the light is from any cause extinguished. A patent has recently been taken out for a stop-cock which appears less likely to get out of order than those commonly used. In this invention the gas is stopped off by a piece of leather which is pressed against a portion of the tube where the gas passes, by means of a brass screw working in a hole at the side of the tube. The gas does not come in contact with the brass-work, so that no corrosion takes place, and a frequent cause of escape is thereby obviated.

Experiment has shown that every burner should have its full supply of gas, as a greater light will thus be obtained without a proportionate increase of consumption. The experiment was tried with an argand burner of three-quarters of an inch in diameter; a sufficient quantity of gas was turned on to give a light equal to that of a mould candle; the consumption in this case was a foot and a half per hour. The light was then increased until it equalled four candles, but notwithstanding the light was quadrupled, the consumption of gas was not even doubled; it was only two feet per hour, or half a foot per candle; while in the first trial, the light of one candle consumed a foot and a half, or three times as much. The following statement shows the result of the whole experiment, which was continued as long as the burner consumed all the gas that was admitted; when that

quantity was exceeded the flame became smoky, and the experiment was stopped:—

Light produced.		Consumption per hour.		Consumption of each Candle's Light.
1 candle	..	1·43 feet	..	1·43 feet
4 "	..	1·96 "	..	·49 "
6 "	..	2·40 "	..	·40 "
8 "	..	2·95 "	..	·37 "
10 "	..	3·10 "	..	·31 "

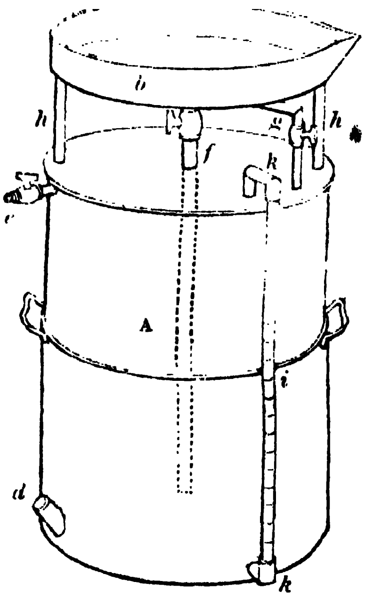
It is evident from this experiment that it is more economical to diminish the number of burners than the supply of gas; and we are of opinion that a plan might be devised by which one or more of the little holes with which a burner is perforated might be stopped off when the light is to be diminished, instead of effecting the same object by lowering the gas.

GASCOIGNE, SIR WILLIAM. [HENRY V.]

GASCONY. [GUIENNE.]

GASHOLDER and GASOMETER. These are vessels employed in the preparation, preserving, and using such gases as are insoluble in water, and employed in chemical investigations.

Many varieties of these have been invented. That which is most useful is Pepys's improved gasometer, of which the annexed cut is a representation. It consists of a copper



cylinder A, on the top of which is supported, by the legs *h h*, the pan or cistern *b*. The hollow cylinder A is plain on the inside, except a small projection at the bottom of *d*. It has the following six openings into it:—From the top proceed the pipes *f* and *g*, each of which also communicates separately with the pan *b*; *f*, as shown by the dotted lines, extends nearly to the bottom of A. The short tube *e* also opens directly into the upper part of the cylinder; *d* is a pretty large opening formed by a short pipe which enters the cylinder at an angle of about 45°, and passes down for an inch or two in the same direction. At this angle the water will not run out through it from the cylinder A, provided all the tubes that would admit the pressure of the air are closed by turning off the cocks. This opening *d* has a stopper which may be screwed on when wanted. Besides these four openings, which are essential to the apparatus, there are two others, *k k*, one at top and the other at bottom, which communicate only with the graduated glass tube *i*, soldered into *k k*, which is of brass: the use of this is to show the level of the water within the cylinder; and the quantity of gas is also read off on the scale.

The cylinder is filled with water by pouring it into the pan *b*; *d* and *e* being closed, and *f* and *g* remaining open, the water runs down into the cylinder, principally at *f*, and the air is expelled from it by the tube *g*, at an opening in the bottom of the pan. When the cylinder A is quite full of water, which is known by inspecting the glass-tube, stop the cocks at *f* and *g*, and open *d*, and the water, as already mentioned, will not flow out. Then introduce the beak of the retort, or the tube from which gas is to issue, so deep into *d* that it projects beyond the inner edge. As the gas rises into A it displaces an equal bulk of water, which now escapes through *d* by the side of the retort beak, or tube which conveys the gas. When the gasometer is so full that the level of the water falls to the bottom of the glass tube, take out the retort, and shut the tube *d* by means of the stopper or screw. The gasometer, now filled with gas, may be safely conveyed anywhere without loss or admixture with the air of the atmosphere.

This apparatus answers various purposes. First, if a bottle or deflagrating jar is to be filled with oxygen or other gas, fill the bottle with water and invert it in the pan *b*, also containing water, and place it over the opening *g*; then open the cocks at *f* and *g*, and the water will sink into the cylinder at *f*, and an equal quantity of gas will rise at *g* and displace the water from the bottle. When this is filled, again shut the cocks at *f* and *g*. If it be required to fill a bladder with gas, screw it on the cock at *e*, open the cock at *f* and let the water sink into the cylinder, and the gas will rise as it did before, but will escape at *e* into the bladder. The opening at *e* is also used for supplying a blow-pipe with gas; this is screwed on and connected with a flexible tube.

This instrument is rather a *gasometer* than a mere gasholder—the latter is a simpler instrument, upon the same principle; but though it may be used for filling a bladder with gas, it cannot be used for filling bottles nor for supplying a blow-pipe.

GASSENDI, PIERRE (properly Gassend), one of the most distinguished of the naturalists, mathematicians, and philosophers of France, was born 22nd January, 1592, at Chantersier, a village near Digne, in the department of the Lower Alps, of poor parents. Richer in virtue than in worldly goods, they were content to sacrifice their own enjoyments to the education of their child, who, before he reached his fifth year, had already given many premature indications of extraordinary powers. At a very early period he evinced a taste for astronomy, which became so strong, that he is said to have often deprived himself of sleep in order to enjoy the contemplation of the heavens; and the following anecdote betokens the precocious development of that talent of observation and deduction for which he was in after-life so eminently distinguished. A dispute having arisen one evening between some children of his own age whether the moon or clouds were moving, and his companions maintaining that the apparent motion was that of the moon, but that the clouds were stationary, Gassendi proceeded to undeceive them by ocular proof: placing his playfellows beneath a tree, he bade them notice that while the moon was steadily visible between the same branches, different clouds were constantly appearing in succession.

Gassendi was sent to school at Digne, where he made rapid progress in the Latin language, and soon acquired a decided pre-eminence over his schoolfellows. Upon completing the usual course, he returned to Chantersier in order to prosecute his studies in retirement; but he had not been there long when he was invited, at the early age of sixteen, to teach rhetoric at Digne. This office he shortly relinquished, and proceeded to Aix to study divinity. In 1614 he was appointed professor of theology at Digne, and two years afterwards he was invited to Aix to fill the chairs of divinity and philosophy, vacant by the death of Fesac, his master and teacher.

The careful perusal of the works of Vives, Ramus, and Patricius, had thoroughly convinced Gassendi of the faults and defects of the philosophy of the schoolmen, or the so-called followers of Aristotle, but it required no ordinary boldness to call it in question. Animated however by the spirit of truth and free inquiry, Gassendi did not hesitate to submit the principles of the schoolmen to a rigorous and searching criticism, and considered it his duty, as a professor of philosophy, to expose the errors of the prevailing theory. This he did indirectly in a work entitled 'Exercitationes paradoxicæ adversus Aristoteleos.' The appearance of the first volume, which was published at Grenoble in 1624, gained for its author a well-established and wide-spread reputation; and if on the one hand it gave great offence to the blind partisans of established doctrines, it was on the other highly esteemed by several learned and distinguished individuals, and particularly by Nicholas Peiresc, president of the university of Aix, by whose interest and influence, assisted by Joseph Walter, prior of Valette, Gassendi was promoted to a canonry in

the cathedral of Digne, where he was admitted to the degree of doctor in divinity, and appointed prevôt of the church. This new situation, which enabled him to vacate the chair at Aix, allowed to Gassendi the undisturbed disposition of his time, which he devoted to the diligent prosecution and advancement of astronomy and anatomy, and to the study of classical literature, and of the works of the ancient philosophers. As the result of his anatomical researches, he composed a treatise to prove that man was intended to live upon vegetables, and that animal food, as contrary to the human constitution, is baneful and unwholesome. In 1629 a second volume of his 'Exercitationes' appeared, the object of which was to expose the futility of the Aristotelian scholastic logic. At the same time five more volumes, in further consideration of the same subject, were announced; but in consequence of the bitter hostility which his attacks upon the favorite system had awakened in its advocates, Gassendi deemed it prudent to abandon the design.

In 1628 Gassendi visited Holland with a view to gain and to cultivate an acquaintance with the philosophers of that country. During his residence there he composed, at the instance of his friend Mersenne, the work entitled 'Examen Philosophicum Robti. Fludd,' in answer to the dissertation of our countryman on the subject of the Mosaic philosophy. Upon his return to Digne, Gassendi applied himself with great diligence to astronomical studies, for which his fondness had grown with his years, and he had the good fortune, on the 7th November, 1631, to be the first to observe a transit of the planet Mercury over the sun's disc which had been previously calculated by Kepler.

In the year 1641, being called to Paris by a law-suit arising out of the affairs of the chapter, his amiable disposition and brilliant talents obtained for Gassendi the regard and esteem of the most distinguished persons of the metropolis of France, and the friendship of the Cardinal Richelieu and of his brother the Cardinal du Plessis, archbishop of Lyon. At this period Des Cartes, with whom Gassendi had long maintained a close and friendly intercourse, was working a reform in philosophy, and by the publication of his 'Meditationes' had opened for it a new and more useful career. In this work however Gassendi discovered much that was objectionable, and forthwith attacked the philosophical system of his friend in a work entitled 'Disquisitio Metaphysica, seu Dubitationes ad Meditationes Cartesii,' which was put into the hands of Des Cartes by their mutual friend Mersenne. Des Cartes wrote an answer, which he published together with the 'Doubts,' under the head, 'Sixth Objection to the Meditations.' In 1643 Gassendi composed the 'Instantiæ' in reply, and circulated them in MS. in Paris before he sent them to M. Sorbière to be printed at Amsterdam. The latter circumstance tended to confirm and widen the difference which, in the course of the controversy, had grown up between the two friends, who however entertained a sincere respect for each other, and were eventually reconciled by the kindly offices of a common friend, the Abbé d'Estrées. Baillet, the biographer of Des Cartes, ascribes the publication of the 'Doubts' to secret jealousy of the growing fame of the author of the Meditations, and to chagrin on the part of Gassendi at the omission in Des Cartes's Treatise of Meteors of his Dissertation upon the singular phenomenon of two parhelia which had been observed at Rome. But the mind of Gassendi seems to have been superior to the influence of such paltry motives, and the origin of the work in question may more justly be referred to the love of truth, which to Gassendi was dearer than friendship itself. Moreover, there was much in their respective characters that was calculated to lead to difference of opinion upon speculative matters. Carried away by a lively imagination, Des Cartes thought it sufficient to draw from his own mind and his individual consciousness the materials for constructing a new system of philosophy; whereas Gassendi, a man of immense learning, and the declared enemy of whatever had the appearance of novelty, was strongly biassed in favour of antiquity. Chimæra for chimæra, he preferred that which had at least the prescription of 2000 years in its favour. From Democritus and Epicurus, whose opinions were above all others most easily reconcileable with his own scientific information, Gassendi drew whatever was well-founded and rational in their system to form the basis of his own physiology. Having restored the doctrine of Atoms and a Void with such slight modification that at most perhaps he did but lend to it a modern style and language, his philosophy had the glory of dividing with Des Cartes the empire of the French philosophical world.

In 1645 Gassendi was appointed professor of mathematics in the College Royal of Paris, upon the nomination and by the influence of Cardinal du Plessis. As this institution was intended principally for the advancement of astronomy, he read lectures upon that science to a crowded and distinguished audience, by which he increased the reputation he had previously acquired, and quickly became the focus of the literary activity of France, so far as it was directed to his favourite sciences of mathematics and astronomy.

But the intensity of his studies had undermined the constitution of Gassendi, and a severe cold having occasioned inflammation of the lungs, he was forced to retire to Digne for the restoration of his health. In this retirement however he was far from idle. In 1647 he published his principal work, 'De Vitâ et Moribus Epicuri,' in which he clears the character of this philosopher from the mist of prejudice with which it had been invested and unfairly handed down to posterity. The 'Syntagma Philosophiæ Epicureæ,' which followed in 1649, is an attempt to reconstruct the system of Epicurus out of the extant fragments, and to give a complete and connected exposition of his theory. Notwithstanding the express refutation, which Gassendi subjoined, of the errors, both physical and moral, of this philosopher, and despite the purity of his own moral character and the exactitude of his religious observances, the sincerity of his religious belief was doubted by those who were constrained to admit the learning and critical acuteness which the work displayed; eventually however the injustice of the calumny redounded to the disgrace of his envious traducers.

His native air having produced a considerable amelioration in his strength, Gassendi was able to return to Paris in 1653, and the next year he published 'Tychonis Brahaei, Copernici, Peurbachii, &c. Vitæ,' a work which was not confined to the biography of these great men, but also contained a brief sketch of antient and modern astronomy down to his own day. The resumption of his literary labours quickly brought on a return of his former disorder, and he died on the 14th October, 1655, in the sixty-third year of his age. His valuable collection of books and his astronomical and philosophical apparatus were purchased by the Emperor Ferdinand III., and deposited in the Imperial library at Vienna.

The philosophical reserve and moderation of Gassendi have led Bayle to designate him as a sceptic, which however, to judge at least from his writings, is little in accordance with the spirit of his philosophy; for although he often complains of the weakness of human reason, which even in the sphere of physical investigations is constantly at fault, and therefore admits the insufficiency of his own discoveries to satisfy either himself or others, this circumstance, while it rendered him patient in controversy and unwilling to enforce his own conclusions upon others, only proves at most that his dogmatism was not as one-sided and immoderate as that of other dogmatists, and that even while he insisted upon the possibility of establishing positive results, he was yet sceptical enough to doubt the finality of his own positions.

By the philosophical cast of his mind and the variety of his acquirements, as well as by the amiable moderation of his character, Gassendi was one of the brightest ornaments of his age. Bayle has justly styled him the greatest philosopher among scholars, and the greatest scholar among philosophers. He may have been surpassed by some of his contemporaries in particular departments of inquiry, as, for instance, by Des Cartes, in the higher branches of mathematics, yet none came near to him in reach and universality of genius. Varied as was his erudition, it did not overpower the clearness of his intellect, the too common result of great learning; on the contrary, his works are distinguished for the perspicuous arrangement of the ideas, the justice of the reasoning, the acuteness of the criticism, and the pre-eminent lucidness of the style and diction.

The works of Gassendi were collected by Montmort and Sorbière, 6 vols., fol., Lyon, 1658; and by Averrani, 6 vols., fol., Firenze, 1728. There is a life of Gassendi by Sorbière, prefixed to the collected works, and one by Bougerel, Paris, 1737.

GASTERO'PODA,* the third class of Mollusks, according to the system of Cuvier, who remarks that it is very numerous, and that an idea may be formed of it from the slugs and shell-snails. Before we proceed to the sections, or rather orders, into which Cuvier has subdivided this extensive congregation, it will be necessary to put the reader in possession of his views of the conformation necessary to bring a molluscous animal within the class of Gastropods.

These mollusks, then, according to the great French zoologist, generally creep upon a fleshy disk placed under the belly; but which sometimes takes the form of a furrow or that of a vertical plate. The back is furnished with a mantle, which is more or less extensive, presents diversities of form, and, in the greatest number of genera, produces a shell. The head, placed in front, shows itself more or less, according to its greater or less retirement under the mantle, and is furnished with small tentacles, which are above the mouth, and never surround it. Their number ranges from two to six, and they are sometimes altogether wanting. Their proper use is only for touching, and, at the most, for smelling. The eyes are very small, sometimes adhering to the head; sometimes at the base, or at the side, or at the point of the tentacle; and sometimes these organs are altogether wanting. The position, the structure, and the nature of the respiratory organs vary, and afford grounds for dividing the animals into many families; but they never have any other than a single aortic heart, that is to say, placed between the pulmonary vein and the aorta. The site of the apertures by which the organs of generation come out and that of the vent vary; but they are nearly always on the right side of the body.

Many of the Gastropods are absolutely naked; others have only a concealed shell; but the greater number carry a shell, which is capable of receiving and sheltering them.

These shells are produced in the thickness of the mantle; some of them are symmetrical, consisting of more pieces than one; others are symmetrical, but formed of a single piece; and there are also some non-symmetrical, which in species where they are very concave, and where they grow a long time, necessarily produce an oblique spire. If the reader will imagine an oblique cone in which other cones are successively placed, always larger in a certain direction than in the others, it will follow that the whole rolls itself upon the side which is least. The part on which the cone is rolled is called the *Columella*, or *Pillar*: this is sometimes solid, and sometimes hollow. When it is hollow, the open end of it is named the *Umbilicus*. The whorls of the shell may remain nearly on the same plane, or may extend towards the base of the columella. In the last case, the preceding whorls are raised one above the other, and form what is called the *Spire*, which is pointed in proportion to the more rapid descent and small enlargement of the whorls. Those shells with an elongated or projecting spire are termed *Turbinated Shells*. When, on the contrary, the whorls remain nearly on the same plane, and are not enveloped one within another, the spire is flat or even concave. These are called *Discoïd Shells*. When the upper part of each whorl envelops the preceding ones, the spire is said to be concealed. That part of the shell from which the animal comes forth is termed the *Aperture*. When the whorls remain nearly on the same plane, the animal, when it creeps, carries its shell disposed vertically, the columella lying across the posterior part of the back; and its head passes under the border of the aperture opposed to the columella. When the spire is elongated, it is directed obliquely to the right in almost all the species: a small number only have it directed to the left when they creep; these shells are called *Reversed* or *Left-handed Shells*. The heart is always on the side opposite to that where the spire is directed. It is therefore ordinarily on the left side; in the reversed or left-handed shells it is on the right. The contrary of this disposition holds good with regard to the organs of generation.

The organs of respiration, which are always situated in the last whorl of the shell, receive the ambient element under its edge, sometimes by means of the mantle being entirely detached from the body along the whole length of this edge, sometimes in consequence of its being merely pierced by a hole. The border of the mantle is sometimes prolonged into a canal, so that the animal can advance to seek the surrounding fluid without exposing either its head or foot beyond the shell. For this purpose the shell, in such cases, has also on its edge, near to that end of the columella (the base) which is opposed to that whereto the spire tends (the apex), a notch or a canal for the lodgment of that of the mantle. The canal is consequently on the left in the ordinary species, and on the right in the reversed shells. The animal being very flexible, is able to vary the direction of its shell, and most frequently when there is a notch or a canal, it is directed forwards; the spire is thus behind, the columella on the left, and the opposite border, or external lip, as it is termed by some conchologists, on the right. A directly contrary disposition is manifested in the Reversed Shells, and these, in consequence of this contrary disposition, turn towards the left instead of turning towards the right, as in the normal structure. It follows as a consequence that the aperture of the shell, which is formed principally by the last whorl, is more or less large in proportion to the other whorls, accordingly as the head or foot of the animal, which is to be constantly protruded therefrom and retracted thereunto, is more or less voluminous compared with the mass of the viscera which remain fixed within the shell. The aperture is moreover wider or narrower in proportion as the same parts are more or less thick. There are shells whose aperture is narrow and long; the foot, in such cases, is delicate and doubles together for the purpose of re-admission. The greater number of aquatic Gastropods with a spiral shell have an *operculum*, or separate piece, which is sometimes horny, sometimes calcareous, attached on the posterior part of the foot, and which shuts the shell when the animal has re-entered it and is entirely retracted within.

Such is Cuvier's description of the shell which covers the testaceous Gastropods. The organization and general structure of *Shell* will be treated of under the proper head, and will be illustrated with explanatory figures. [SHELL; PEARL.] As far as this work has already proceeded, the reader will find examples of some of the forms of the shells of Gastropods under the articles AURICULA, vol. iii., p. 109; BULINUS, vol. vi., p. 7; BULLADÆ, vol. vi., p. 12; CERVICOBRANCHIATA, vol. vi., p. 440; CHISMOBRANCHIATA, vol. vii., p. 93; CHITONS, vol. vii., p. 94; CONUS, vol. vii., p. 484; CYPRÆIDÆ, vol. viii., p. 254; ENTOMOSTOMATA, vol. ix., p. 450, &c.

Cuvier, in continuation, remarks that there are Gastropods with the sexes separate, and others which are hermaphrodites: of these last some have the power of reproduction without the aid of a second individual, while the others require a reciprocal copulation for the continuation of the species. He adds that the organs of digestion present as many differences as those of respiration, and he divides the class into the following orders.

1. Les Pulmonés, Pulmonifera. (Pulmobranchiata of De Blainville.)

This order is distinguished from the mollusks inasmuch as they respire the elastic atmospheric air by means of a hole opened under the border of their mantle, and which they dilate or contract at their pleasure. They have consequently no *branchiæ*, or gills, but only a net-work of pulmonary vessels, which creep around the walls and principally upon the *plafond* of their respiratory cavity. Some are terrestrial, others aquatic; but these last are obliged to come to the surface of the water from time to time, in order to open the orifice of their pectoral cavity for the purpose of respiration.

The *Terrestrial pulmoniferous mollusks* have all four tentacles; two or three only, of very small dimensions, have not permitted the observer to see the lower pair. They are divided into those which are naked, and those which are protected by a shell. They are all hermaphrodites.

Those which have no apparent shell formed the great genus *Limax* of Linnæus; and of these every one may find examples in the common slugs. [LIMAX.] *Parmacella* and *Testacella* lead the way to

Those which have a complete and apparent shell, the borders of whose aperture, in the majority of instances, are reflected into a little roll *(bourrelet)* when the animal is adult. These were placed by Linnæus under his great genus *Helix*. The shell varies much in form; being, for instance, subglobular or subdiscoïd, as in many of the shell-

* *Gasteropoda*, *Trachelipoda*, and *Heteropoda*, of Lamarck; *Paracephalophora* and *Polyplaxiphora*, of De Blainville; part of the *Heterogangliata* of Owen. The nervous system of the *Heterogangliata* (Acephalans or Conchifers, Gastropods, and Cephalopods) consists of nervous filaments and ganglions for the most part irregularly or unsymmetrically disposed. The *Heterogangliata* comprise all the *Mollusca* of Cuvier, with the exception of the *Cirripeda*.

snails; or elongated and pyramidal, as in *Bulinus*, &c. [HELICIDÆ.]

The *Aquatic pulmoniferous mollusks* have only two tentacula, and always come to the surface to breathe; they do not therefore inhabit deep waters, but live for the most part in the fresh waters or salt lakes, or at least near the sides and mouths of rivers.

Cuvier goes on to give *Onchidium*, Buchanan, (*Peronia* of De Blainville) [CYCLOBRANCHIATA, vol. viii. p. 249] as an example of the Aquatic pulmoniferous mollusks without shells.

Those with shells, which are sometimes discoïd as in *Planorbis*, or elongated and pyramidal, as in *Limnæa*, &c., he illustrates by the genera *Physa*, *Scarabæus*, *Auricula*, and *Conovulus*.

2. Nudibranchiata. (Polybranchiata,—Tritonia, &c., of De Blainville.)

The mollusks composing this order have no shell, nor any pulmonary cavity; but their branchiæ are naked, and placed upon some part of the back. They are all hermaphrodites and marine. They often swim reversed, with the foot concave like a boat, at the surface, aiding their progression with their mantle and tentacles as with oars. A notice of *Doris*, *Polycera*, and *Onchidoris*, three of the genera placed by Cuvier under this order, will be found under the article CYCLOBRANCHIATA, vol. viii. p. 249.

3. Inferobranchiata.

This order presents nearly the same form and organization as the *Dorides* and *Tritoniæ*: but their branchiæ, instead of being placed upon their backs, are arranged in two long rows of leaflet-like appendages on each side of the body under the projecting border of the mantle. *Phyllidia* and *Diphyllidia*, Cuv., belong to the *Inferobranchiata*.

4. Tectibranchiata. (Monopleurobranchiata of De Blainville.)

This order has the branchiæ attached either along the right side or upon the back, in the form of leaflets, which are more or less divided, but not symmetrical. The mantle covers the branchiæ more or less, and almost always contains in its thickness a small shell. The *Tectibranchiata* approach the *Pectinibranchiata* in the form of the organs of respiration, and live like them in the sea; but the *Tectibranchiata* are all hermaphrodites, like the *Nudibranchiata* and *Pulmonifera*. The genera *Pleurobranchus*, Cuv., *Pleurobranchæa*, Meckel, *Pleurobranchidium*, De Blainville *Aplysia*, Linn.; *Dolabella*, Lam.; *Notarchus*, Cuv.; *Bursatella*, Blainv.; *Akera*, Müll.; *Bullæa*, Lam.; part of *Bulla*, Linn.; *Gasteroptera*, Meck.; *Umbrella*, Lam.; *Gastroplex*, Blainv.:—belong to this order. The reader will find a notice of BURSATELLA under that head, vol. vi. p. 47, and of *Akera*, *Bullæa*, *Bulla*, and *Gasteroptera*, under the title BULLADÆ, vol. vi. p. 11. The *Aplysiacea*, including *Dolabella*, *Notarchus*, &c., will be noticed under the title TECTIBRANCHIATA; and *Umbrella*, under that of PATELLOIDEA.

These four orders are united by M. de Blainville under the name of *Paracephalophora Monoica*.

5. Heteropoda, Lam. (Nectopoda, Blainv.)

Distinguished from all the others, inasmuch as their foot, instead of forming a horizontal disk, is compressed into a muscular vertical plate, which serves them as a fin, and at the edge of which, in many species, a dilatation, in form of a hollow cone, represents the disk of the other orders. Their branchiæ, formed of feathery lobes, are situated on the posterior part and left side of the back, directed forwards; and immediately behind them are the heart and a liver of no great size, with a part of the viscera and the internal organs of generation. Their body, lined with a muscular coat, is elongated, terminating most frequently by a compressed tail. Their mouth is formed by a muscular mass, and is furnished with a tongue beset with small hooks. The œsophagus is very long, the stomach delicate in texture, and two tubes at the right side of the packet of viscera give exit to the excrements and to the ova or to the prolific fluid. They generally swim with the back downwards and the foot above, and they can swell out their bodies by filling them with water by means which are not as yet well understood.

To this description Cuvier adds, that the method of swimming above described having induced Peron to believe that the natatory plate was on the back, and the heart and branchiæ under the belly, has given rise to many errors as to the proper place of these animals. Cuvier adds, that the examination of their nervous system led him to the opinion expressed in his memoir on the *Mollusca*, that they were analogous to the Gastropods. A more complete dissection, he observes, made since, and that given by Poli, in his third volume, have completely confirmed this conjecture, and he states that the fact is that the *Heteropoda* differ but little from the *Tectibranchiata*. M. Laurillard believes that the sexes are always separate. Cuvier also remarks, that M. de Blainville makes of his (Cuvier's) *Heteropoda* a family which he names *Nectopoda*, and unites them with another family which he names *Pteropoda*, and which comprehends none of Cuvier's Pteropoda, except *Limacina*. To this, Cuvier observes, M. de Blainville refers *Argonauta*, upon what conjecture Cuvier knows not.

Forskal places all the *Heteropoda* of Cuvier under his genus *Pterotrachea*.

In this work, the type of the family, CARINARIA, is described and figured under that title, vol. vi. p. 294, and ATLANTA is noticed and figured in vol. iii. p. 24. The other genera will be found under the article HETEROPODA.

6. Pectinibranchiata. (Paracephalophora Dioica, Blainv.)

This order is by far the most numerous division of the Gastropods, for it embraces nearly all those which have spiral univalve shells, and many of those whose shells are simply conical. Their branchiæ, composed of numerous leaflets or fringes (lanières) ranged in parallel order like the teeth of a comb (whence their name), are attached upon one, two, or three lines, according to the genus, to the *plafond* of the pulmonary cavity, which occupies the last whorl of the shell, and which forms a large opening between the border of the mantle and the body. Two genera only (*Cyclostoma* and *Helicina*) have, in the place of branchiæ, a vascular net covering the *plafond* of a cavity similar in other respects: these are the only genera which breathe air; all the others respire water.

All the *Pectinibranchiata* have two tentacula and two eyes sometimes carried on their proper peduncles, a mouth in form of a proboscis, which is more or less elongated, and the sexes separate. The intromissive organ of the male, which is attached to the side of the neck, cannot ordinarily be retracted into the body, but is reflected in the branchial cavity, and is sometimes very large, as may be seen in the figure of *Buccinum undatum* (ENTOMOSTOMATA, vol. ix. p 454), which will give a general idea of the form of a marine Pectinibranchiate testaceous mollusk, with a turbinated shell. *Paludina* indeed can cause this organ to re-enter the body by an orifice pierced at its right tentacle. The rectum and oviduct of the female creep also along the right side of the branchial cavity, and between them and the branchiæ is a particular organ composed of cellules containing a very viscous liquor, serving to form a common envelopment or case, which includes the eggs, and which the animal deposits with them. Several of these deposited ovaries present very complicated and singular forms, and may be often found on the sea-beach.

The tongue of the *Pectinibranchiata* is armed with small hooks, and files down the hardest bodies by slow and repeated friction.

The greatest difference among these animals consists in the presence or absence of the canal formed by a prolongation of the border of the pulmonary cavity of the left side, and which passes by means of a similar canal, or by a notch in the shell, so as to enable the animal to respire without leaving the shelter of its shell. Some of the genera again are without an *operculum*; and the species also exhibit differences in the filaments, fringes, and other ornaments exhibited on their head, their foot, or their mantle. These mollusks are arranged under many families, according to the form of their shells, which, generally speaking, present a sufficiently constant relation to the form of the animal. But the student should remember that this is not a rule without exception, as Mr. Gray has pointed out in his interesting paper in the 'Philosophical Transactions.'

The reader will find the numerous genera—the leading ones at least—of this most extensive order, principally under the titles of the different families into which they have been separated by zoologists; and sometimes under their generic appellations.

7. Tubulibranchiata.

Cuvier considers that this order should be detached from

the *Pectinibranchiata*, to which they nevertheless bear great resemblance, because their shell (which is in the form of a tube more or less irregular, the commencement of which only is turbinated or spiral) is fixed to different foreign bodies: they have in consequence no true copulative organs, and fecundate themselves. *Vermetus*, *Magilus*, and *Siliquaria* (all marine) belong to this order.

8. Scutibranchiata. (Paracephalophora Hermaphroditica, with exception of the Chitons, De Blainv.)

This order consists of Gastropods which bear a near relationship to the *Pectinibranchiata* in the shape and position of the branchiæ, as well as in the general form of the body, but which have the sexes united in the same individual. The shells of this order are always without an operculum, very wide in the opening (some of them may be said to be almost all aperture), and many of them have shells without any turbination, so that they cover the animal, and especially its branchiæ, like a shield. The heart is traversed by the rectum, and receives the blood by two auricles, as in the generality of Bivalves. Under this order Cuvier, in his last edition of the 'Règne Animal' places the *Haliotidæ* (Ear-shells), *Stomatia*, *Fissurella*, *Emarginula*, and *Parmophorus*. The reader will find *Fissurella*, *Emarginula*, and *Parmophorus* treated of in the article CERVICOBRANCHIATA, vol. vi. p. 443.

9. Cyclobranchiata.* (Cervicobranchiata, Blainv.)

Branchiæ in form of small leaflets or little pyramids, attached in a *cordon* more or less complete under the borders of the mantle, nearly as in the *Inferobrachiata*, from which the *Cyclobranchiata* are distinguished by their hermaphroditism; for they have no organs of copulation, and can reproduce the species without having recourse to a second individual. The heart does not embrace the rectum, but it varies in situation.

The genera *Patella* and *Chiton*, the only forms admitted by Cuvier to belong to his Cyclobranchians, are treated of under the articles CERVICOBRANCHIATA and CHITONS.

Such is Cuvier's arrangement; and, based as it is on anatomical investigation, there can be no doubt that, as a whole, it rests on a sure foundation, however necessary it may be for the more ready classification of the forms to have recourse to arbitrary methods. M. Rang adopts it, adding as orders De Blainville's *Nucleobranchiata* for Lamarck's *Heteropoda*, and De Blainville's *Cirrhobranchiata* for the genus *Dentalium*. [DENTALIUM, vol. viii., p. 404.]

FOSSIL GASTEROPODA.

A class which comprehends so great a number of animated organized beings, having the most extensive geographical range—a class embracing an immense mass of mollusks, multitudes of which are littoral, many terrestrial and inhabitants of the fresh waters, and a considerable number pelagic, for the most part protected by hard calcareous shells, presents materials, in a fossil state, of the greatest consequence to the geologist for decyphering the mineral structure of the earth.

Mr. Dillwyn, as is noticed by Dr. Buckland in his 'Bridgewater Treatise,' asserts that every fossil turbinated univalve of the older beds, from the transition lime to the lias, belongs to the herbivorous genera; and that the herbivorous class extends through every stratum in the entire series of geological formations, and still retains its place among the inhabitants of our existing seas. On the other hand the shells of marine carnivorous univalves are very abundant in the tertiary strata above the chalk, but are rare in the secondary strata from the chalk downwards to the inferior oolite; beneath which no trace of them has yet been found. Dr. Buckland further seems to be of opinion that, in the economy of sub-marine life, the great family of carnivorous trachelipods performed the same necessary office during the tertiary period which is allotted to them in the present ocean, and he alludes to the evidence showing that in times anterior to and during the deposition of the chalk, the same important functions were consigned to other carnivorous mollusks (the testaceous cephalopods), which are of comparatively rare occurrence in the tertiary strata in our modern seas; but throughout the secondary and transition formations, where carnivorous trachelipods are either wholy wanting or extremely scarce, there occur abundant remains of carnivorous cephalopods, consisting of the chambered shells of nautili and ammonites, and many kindred extinct genera of polythalamous shells. Their sudden and nearly total disappearance, as Dr. Buckland remarks, would have allowed the herbivorous tribes to increase to an excess that would ultimately have been destructive of marine vegetation, as well as of themselves, had they not been replaced by a different order of carnivorous creatures destined to perform in another manner the office executed by the various extinct genera of testaceous cephalopods. 'From that time onwards,' continues Dr. Buckland, 'we have evidence of the abundance of carnivorous trachelipods, and we see good reason to adopt the conclusion of Mr. Dillwyn, that in the formations above the chalk the vast and sudden decrease of one predaceous tribe has been provided for by the creation of many new genera and species, possessed of similar appetencies, and yet formed for obtaining their prey by habits entirely different from those of the cephalopods.'

The reader will find the fossil Gastropods noticed more in detail under the titles of the different families and genera.

GASTERO'PTERA. [BULLADÆ, vol. vi., p. 13.]

GASTERO'STEUS. [STICKLEBACK.]

GASTRIC JUICE. This term is applied to the fluid, secreted from the interior of the stomach, which is the principal agent in digestion. The gastric juice is a transparent slightly viscid liquid, which, when obtained from the stomach of an animal while fasting, possesses neither acid nor alkaline re-action, but has a saline taste. During the process of digestion, on the contrary, it is distinctly acid. Gastric juice possesses strong antiseptic properties, suspending putrefaction, and restoring the freshness of tainted meat: it also coagulates milk, which property is independent of the presence of any acid. But the most remarkable quality of the secretion of the stomach is its solvent effect, which will even act on nutritive substances out of the body. This power of solution cannot be explained satisfactorily on chemical principles, as there appears to be little connection between the properties and composition of this fluid. Tiedemann and Gmelin have ascribed its solvent qualities to the action of muriatic and acetic acids, which they say are always secreted during the digestive process; but they have not shown that, when in its neutral state, it is devoid of the solvent action, which proof is necessary to determine that the presence of the acid is indispensable. The chemical composition of gastric juice is involved in much obscurity from the difficulty of obtaining this fluid in a pure state, but it does not differ materially from that of some other animal fluids, as saliva, or from the secretions of mucous membrane generally: it consists of a large proportion of water, with some mucus, and certain salts in small quantities, the most plentiful of which is muriate of soda. The free muriatic acid which is sometimes found should rather be considered as developed during the process of digestion, and not as entering into the regular constitution of the fluid. With regard to the origin of the gastric juice, it is secreted by numerous small glands situated beneath the mucous membrane, and opening into the stomach by many minute apertures, from the orifices of which the fluid may be seen with a microscope to distil. These glands of the stomach are single, and vary in diameter from ·02 to ·08 of an inch; the largest are situated towards the fundus of the organ, the smaller towards the pylorus. The use of the gastric juice is to act on the food as a chemical solvent, and thus perform the first process of digestion; the office of the stomach being to convert the nutritive materials of food into a uniform semifluid mass, called chyme; which change is wrought, as many experiments have shown, through the exclusive influence of the fluids of the stomach. [DIGESTION.]

GASTROCHÆ'NA, a genus of Acephalous Mollusks or Conchifers, established by Spengler. Lamarck places it between *Pholas* and *Solen*, and Cuvier between *Fistulana* and *Teredina*. M. Deshayes, in his edition of the '*Animaux sans vertèbres*,' says that it is evident that Lamarck came to very erroneous conclusions as to this genus. The animal, observes M. Deshayes, has two posterior very short siphons when it is contracted; the lobes of the mantle are united up to the gape of the valves and even a little higher; this gaping of the valves, as well as the divarication of the

* The *Cyclobranchiata* are, in Cuvier's last edition of the 'Règne Animal,' headed 'Huitième ordre des Gastéropodes,' and they are cited as the 8th in the articles CERVICOBRANCHIATA, vol. vi. p. 440, and CYCLOBRANCHIATA, vol. viii. p. 248. The preceding order, *Scutibranchiata*, has the same heading: but the *Cyclobranchiata* form the 9th order; and Cuvier appears to have forgotten that he had published the *Tubulibranchiata*, an order which it seems probable from this repetition he may have intercalated.

lobes of the mantle, gives passage to a great short cylindrical foot, like that of the *Pholades*; but this opening is not at all destined for the passage of the siphons, as Lamarck supposed.

Mr. G. B. Sowerby ('Genera of Recent and Fossil Shells') remarks, that the genera *Pholas*, *Mya*, *Mytilus*, and *Chama*, have by turns served as a receptacle of the shells of this genus. He observes, that Lamarck has adopted Spengler's name, but has placed it next to *Pholas*, apparently not having known that the animal forms its own testaceous tube, either as a lining to the hollow it has previously perforated, or as a covering for its shell in those instances in which it has not perforated at all, but in which it has taken up its abode, as it frequently does, within some spiral univalve. Mr. Sowerby is further of opinion, that the fact of the shell being enclosed in a testaceous tube of its own depositing, renders it proper to remove it into Lamarck's family of *Tubicolæ*, to which indeed it appears to Mr. Sowerby to be more nearly related, though he notices a very considerable analogy between the shelly tube of Lamarck's *Tubicolæ*, and the coriaceous epidermis, which not only in a great measure covers the shell, but also encloses the tubes of the animal of Lamarck's *Pholadaceæ*, and Mr. Sowerby consequently thinks that the two families might very properly be united.

Mr. Owen, in his paper on *Clavagella*, remarks how closely that form follows the modifications which have been observed in *Gastrochæna*. [CLAVAGELLA, vol. vii., p. 244.]

Cuvier says that it appears that the *Gastrochænæ* constantly have a calcareous tube, and quotes Dr. Turton, M. Deshayes and M. Audouin as having observed it.

M. Rang says that all the *Gastrochænæ* have not a calcareous tube, though all of them burrow in stones after the manner of *Pholades*. If this is to be taken literally, it does not exactly accord with the fact; for, sometimes, the animal does not burrow at all, at others (and very frequently) it burrows in madrepores. M. Rang adds that two of the species which belonged to the genus *Fistulana* of Lamarck are now arranged in this, and that this arrangement is due to M. de Blainville. These two species, he says, are *Fistulana clava* and *F. Ampullaria*. Of these, *Fistulana clava* is referred, among the synonymes, to *Gastrochæna*, by Lamarck, and *Fistulana ampullaria* is declared by M. Deshayes to be a true *Fistulana*, but remarkable in this, that, according to circumstances, it forms a free tube sunk in the sand, or perforates calcareous bodies, and its tube serves as a lining to the cavity which it inhabits; this species therefore, he observes, would belong to the *Fistulanæ* in the first case, and to the genus *Gastrochæna* in the second; if indeed that genus be preserved.

M. Rang states that M. Charles Des Moulins, who a long time ago, and before the observations made upon this subject, had discovered the existence of a tube in the *Gastrochænæ*, had shown him this tube, not only in the living species on the French coast, but in the fossil at Merignac. Following De Blainville, M. Rang would divide the genus *Gastrochæna* into the two following groups.

α

Species whose shell is smooth and without a distinct tube. Example. *Gastrochæna cuneiformis*, &c.

β

Species whose shell is striated from the umbo to the base, and contained in a distinct tube.

Example. *Gastrochæna clava.*

M. de Blainville states that the animal of *Gastrochæna* has evidently the greatest relationship to that of *Saxicava*; but as it is not entirely contained in its shell, it often supplies the deficiency by forming an artificial tube adhering to the walls of the cavity which it inhabits in calcareous stones.

This tube, in the opinion of M. de Blainville, offers only an accidental character, and would thus make of species, or even of individuals which are provided with it, *Fistulanæ* of Lamarck. Thus, he observes, M. Deshayes has proposed to suppress the genus *Gastrochæna*, but he would consider it more convenient not to admit the genus *Fistulana*; first, because it is founded upon the presence of a tube; and, secondly, because it was established some time after *Gastrochæna*. He would however prefer its restriction as he has restricted it in his *Malacologie*. In uniting the species characterized by the true shell, whether it have an external tube or not, there exist already, he remarks, many species of known *Gastrochænæ*, both living in the seas of warm climates and fossils in his country. M. Defrance, he states, nevertheless quotes one fossil species only at Grignon, and an analogue; and he concludes by observing that *Gastrochæna clava* would perhaps, if it were better known, form a small distinct genus.

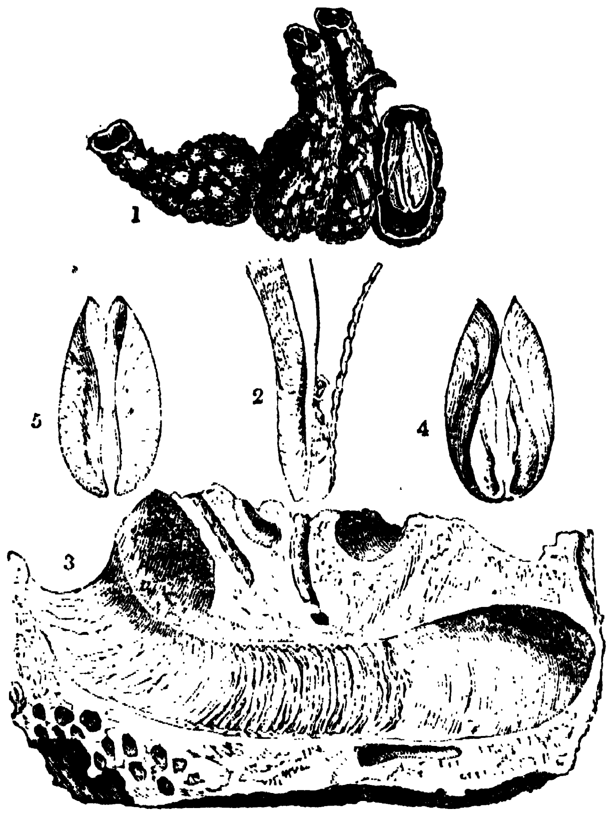
Mr. G. B. Sowerby (*Zool. Proc.* 1834) describes five new species brought home by Mr. Cuming from South America, and the Gallapagos and Lord Hood's Islands.

The following is M. Rang's definition of the genus:—

Animal oval, having the mantle closed with a very small anterior rounded opening for the passage of a small, conical, or linguiform foot: the tubes elongated and united throughout.

Shell delicate, oblique, oval, cuneiform, equivalve, very inequilateral, gaping extremely at its antero-inferior part; *umbones* well marked; *hinge* straight and linear without teeth; an apophysis often showing itself below the hinge in the interior of each valve; *ligament* external; *muscular impressions* distinct, connected by a slightly marked pallial impression excavated posteriorly.

Sometimes a calcareous tube, ampulliform, short, with a rounded aperture, enveloping the shell and lining the cavity of the stone.



1, A group of the tubes of Gastrochæna modiolina, Lam. (Mediterranean): one of the tubes is broken and shows the valves in situ; 2, Fusus Noæ (Grignon) cut open to show the clavate tube of a small fossil Gastrochæna; 3, a worn fragment of a Madrepore, broken to show the tube formed by a specimen of Gastrochæna cuneiformis, Lam.; 4 and 5, two views of the two valves of the last-mentioned species. (From the 'Genera of Recent and Fossil Shells,' by G. B Sowerby, now (January, 1838) in the course of publication, and almost complete.)

The depth at which living *Gastrochænæ* have been found ranges from 3 to 17 fathoms.

FOSSIL GASTROCHÆNÆ.

Among the fossil *Gastrochænæ*, *Gastrochæna tortuosa* has been found in the inferior oolite (Phillips); and Dr. Fitton, in his Stratigraphical Table, records *Gastrochæna* (species doubtful) in the lower green sand, in the Portland stone, in the Portland sand, in the Oxford oolite, and in perforations in dicotyledonous (silicified) wood;—*Gault*, east of Folkstone.

GA'STROPLEX. [GASTEROPODA, vol. xi., p. 92; PATELLOIDEA.]

GATAKER, THOMAS, born in London in 1574, studied at Cambridge, where he took his degrees, was afterwards chaplain to Sir William Cook, and also preacher to the Society of Lincoln's Inn. He applied himself especially to the study of the Scriptures in the Hebrew and Greek text, and wrote several works in illustration of the Old Testament. He also wrote 'Of the Nature and Use of Lots,' a treatise historical and theological, in which he distinguishes between innocent and lawful games of chance, and

those which are unlawful or reprehensible. His arguments having been misrepresented, he had to sustain a polemical correspondence in his own justification. In 1611 he was appointed rector of Rotherhithe. In 1624 he wrote a treatise against Transubstantiation. In 1642 he was chosen to sit in the Assembly of Divines at Westminster, where in several instances he differed from the majority. He afterwards wrote with others the 'Annotations on the Bible,' which were published by the same Assembly; the Notes on Isaiah and Jeremiah are by him. In 1648 Gataker, with other London clergymen, to the number of forty-seven, remonstrated against the measures taken by the Long Parliament with respect to king Charles, and he became in consequence an object of suspicion to the ruling powers, but by his mild and open conduct he escaped personal annoyance. In 1652 he published a Latin translation of M. Aurelius' 'Meditations,' with valuable notes, tables of reference, and a preliminary discourse on the philosophy of the Stoics. In the latter part of his life he had to sustain a controversy against the pretended astrologer William Lilly. He died above eighty years of age. His son Charles published his 'Opera Critica,' 2 vols., fol., Utrecht, 1698, which contain, besides the 'Meditations,' his 'Cinnus,' and 'Adversaria Miscellanea,' being disquisitions on biblical subjects, and 'De Novi Testamenti Stylo,' a philological treatise on the antient languages. Gataker's learning has been greatly praised by Boyle and other competent judges.

GATES, HORATIO, a distinguished American general of the Revolutionary war, was born in England in 1728. He received his military training in the English army, served in the West Indies, and accompanied General Braddock in his disastrous expedition against the French settlements on the Ohio in 1755. [BRADDOCK.] Being wounded in that affair, and obliged for a time to retire from active service, he purchased an estate in Virginia. He took the popular side in the Revolutionary troubles, and was appointed adjutant-general on the breaking out of the war. In 1776 he was sent to command the army on Lake Champlain. His conduct at first was not approved of, insomuch that he was superseded in the spring of 1777; but in the following August he was appointed to oppose General Burgoyne, who had forced his way from the Canadian frontier to the Hudson. An indecisive battle was fought September 18th, and a second October 8th, in which the British were defeated. General Gates then blockaded his adversary at Saratoga, who being disappointed in his hope of forming a junction with the Royalist troops on the Hudson, and cut off from all supplies, found it necessary to capitulate with his whole army. For the terms obtained, see BURGOYNE.*

This convention of Saratoga was one of the most important successes gained in the whole war: for near 6000 men surrendered on parole not to serve again, and their arms and artillery were converted to the use of the victors. Gates became the popular hero of the day: and attempts were made by some intriguing partisans, or misjudging friends, to raise him over the head of Washington. Fortunately for America these attempts came to nothing. In June, 1780, he was appointed to command the southern army, which at that time was in a wretched state of disorganization. It was no wonder therefore that on his first meeting with the British troops [CORNWALLIS] he received, though superior in numbers, a total defeat. This took place August 16th, at Camden, in South Carolina. By great exertion he was again in condition to take the field, when he received news that he was superseded by General Greene, and that Congress had resolved to submit his conduct to a court of inquiry. The investigation lasted until after the close of the war in 1782: in the end he was fully and honourably acquitted of blame.

General Gates then retired to his Virginia estate, from which, in 1800, he removed to New York; to the freedom of which city he was immediately admitted. In 1800 he was elected a member of the state legislature. Before his departure from Virginia he performed the noblest act of his life—the emancipation of his slaves, which he accompanied with a provision for those who needed assistance. He died April 10, 1806. (*American Encyclopædia; Hist. Amer. Revolution.*)

GATESHEAD, an antient borough and parish in the eastern division of Chester ward, in the county palatine of Durham, 272 miles N. by W. from London, and 13 miles N. by E. from Durham. It is situated on the southern side of the river Tyne, opposite to Newcastle, with which it communicates by a handsome stone bridge. The parish is about 3½ miles in length, its greatest width being somewhat more than two. Gateshead is supposed to have once been a fortified Roman station, which opinion is supported by the antiquities discovered here at various times, including coins of the emperor Hadrian. Prior to 1833 it was merely a borough by prescription, there being no charter extant, though it is believed to have been once incorporated. By the Reform Act it became a parliamentary borough, and now returns one member. As late as 1681 the town was governed by a bailiff appointed by the bishops of Durham, since which time the government has been vested in two stewards, who possess no municipal authority or jurisdiction, and who are elected annually by the borough-holders and freemen. There are two principal streets; the one descending towards the bridge is so steep as to be almost impassable for carriages during winter; the other, of recent erection, is of gradual descent. The church is an antient and spacious edifice, built in the form of a cross, surmounted by a lofty tower. There are two livings; the rectory of Gateshead and that of Gateshead-fell. The annual net income of the former, according to the Ecclesiastical-revenue Reports, is 636*l.*, and that of the latter 172*l.* They are both in the archdeaconry and diocese of Durham, and in the patronage of the bishop of that see. There are several charitable institutions, among which is an almshouse for poor women. On the east side of the main street are the ruins of an extensive monastery, founded in 1247 by Bishop Farnham, and dedicated to St. Edmund. The town is said to be thriving and increasing annually in manufacturing and commercial importance. It possesses coal-mines, extensively worked, situated within the borough, and which employ a considerable portion of the population of the town. The chief manufactories are of glass, cast and wrought iron, and whitening; and at Gateshead-fell there is an extensive quarry for grindstones, which are exported to most parts of the kingdom. The population of Gateshead and Gateshead-fell in 1831 was 15,177. There are several charity schools, among which is a free grammar-school founded in 1701 by the Rev. Theophilus Pickering, the rector of the parish. Besides Greek and Latin, the children are taught arithmetic and navigation. The revenue of the borough, arising from landed property, is 500*l.*, which is incumbered with a mortgage of 1600*l.* The annual expenditure is about 200*l.* The amount of assessed taxes levied in 1830 was 2036*l.*, and that of the parochial assessments in the following year 4709*l.*—(*Parliamentary Papers*, &c.)

GATINE or GASTINE, a district of Bas (or Lower) Poitou, in France; now comprehended in the department of Deux Sèvres.

GATINOIS, LE, a district in France, partly comprehended in the government of Ile de France, partly in that of Orléanois; and distinguished accordingly as Gâtinois François and Gâtinois Orléanois. Gâtinois was bounded on the north by Hurepoix and Brie François, on the east by Senonois and Bourgogne, on the south by Nivernois and Berri, and on the west by Orléanois Proper and the districts of Beauce and Chartrain. It extended from the Seine to the Loire, and was watered by the Loire, the Seine, the Loing, the Essonne, and their tributaries. It is now comprehended in the departments of Seine et Oise, Seine et Marne, Loiret, and Yonne. Its chief towns were as follows: Le Gâtinois François—capital Nemours, on the Loing (population 3839), Fontainebleau (pop. 8104 town, 8122 commune), Moret, on the Loing (pop. 1673), Beaumont, Château Laudon, Egreville, Milly (pop. 1881 town, 1941 commune), Courtenoy, on the Clery, and Chenoy, on the Lunain, feeders of the Loing; Le Gâtinois Orléanois—capital, Montargis, on the Loing (pop. 6781), Châtillon sur Loing (pop. 1721 town, 2126 commune), Briare (pop. 2243 town, 2730 commune), Gien (pop. 4631 town, 5177 commune), Puiseaux (pop. 1876 town, 1970 commune), and several others.

The district La Puisaye, capital, St. Fargeau (pop. 1519 town, 2132 commune), was a subdivision of Le Gâtinois Orléanois.

The population of the towns is from the census of 1831.

GATSHINA, a regularly-built town on the Ishora where it expands into a lake, about forty miles south of St. Petersburg, in the government of which it is situated.

* In that article the plan of Burgoyne's campaign is misstated: he marched from Canada to the Hudson—not from the Hudson to Canada.

It was a favourite residence of Paul the First, who conferred municipal privileges on it in 1796. It contains a Greek church, Protestant and Roman Catholic chapels, a large hospital, a free school, an asylum for 800 foundlings, a porcelain, a woollen cloth, and a hat manufactory, &c., and, including its dependencies, has a population of about 6500. Between the lake and the hills behind it, and close to Gatshina, is a handsome imperial palace, with a theatre, riding-house, and chapel, all of freestone, and spacious and very picturesque grounds laid out in the English style.

GATTERER, JOHANN CHRISTOPH, born in 1727, near Nürnberg, became professor of history at Göttingen, where he published numerous useful works on antient history, geography, chronology, genealogy, heraldry, and diplomacy, on all which subjects his information was very extensive. His principal publications are:—1. 'Elementa artis Diplomaticæ Universalis,' 4to., Göttingen, 1765, a work of great and curious research, especially concerning the graphic part, or the various characters, monograms, and symbols used in old diplomacy. 2. 'Handbuch der Universal Historie,' 2 vols. 8vo. 1764–5, in which he gives catalogues of numerous writers on the history of the various countries of Europe and Asia, according to the order of time. 3. 'Stammtäfeln zur Weltgeschichte,' 4to., 1790. 4. 'Einleitung in die Synchronistische Universal Historie,' 2 vols. 8vo., 1771, with chronological tables. 5. 'Abriss der Chronologie,' 1777. 6. 'Handbuch der Neuesten Genealogie,' 1772. 7. 'Allgemeine Historische Bibliothek,' 16 vols. 8vo., Halle, 1771. Gatterer died at Göttingen in 1779.

There was another contemporary professor, Christoph Wilhelm Jacob Gatterer, at Heidelberg, who wrote several works on geology and mineralogy.

GAUBIL, ANTHONY, a learned Jesuit, whose labours greatly advanced our knowledge of the literature of eastern Asia, was born in Languedoc in 1689. He entered the society of the Jesuits in 1704, and was sent in 1723 to China, where he applied himself to the study of the Chinese and Mantchoo languages, in which he made such proficiency that the first Chinese scholars sometimes consulted him about obscure and difficult passages in their authors. Besides the above-mentioned literary occupations Gaubil applied himself with great success to mathematics, and particularly to astronomy, without neglecting the numerous avocations of his ecclesiastical calling. Gaubil arrived in China just after the death of the celebrated Emperor Ching-Tsoo, better known in Europe under the name of Kang-Hi, who was very partial to Europeans, but whose successor was imbued with a strong prejudice against the Christian missionaries. Notwithstanding this unfavourable circumstance, Gaubil succeeded in obtaining the favour of the monarch, and was nominated director of the college, where a number of Mantchoo youths are instructed in Latin and Russian*. He was also employed as interpreter from the Mantchoo into Latin, and from Latin into the Mantchoo, for the diplomatical correspondence between China and Russia. Notwithstanding his multifarious occupations, Gaubil found time to write several important works in China, the first of which is an 'Historical and Critical Treatise on the Chinese Astronomy,' published in the 'Observations Mathematiques, Astronomiques, Géographiques et Physiques tirées des anciens livres Chinois, ou Faites nouvellement aux Indes ou à la Chine, par les Missionnaires-Jesuites, requeillies par le P. Souciet (a Jesuit),' Paris, 1729, 1 vol. 4to. The same collection contains the narrative of a 'Voyage from Peking to Canton,' by Gaubil, which has been likewise inserted by Prevot in the 5th vol. of his 'History of Travels.' But the work which reflects the greatest credit on the abilities of Gaubil is his translation into French of the 'Choo-king,' which contains the earliest traditions respecting the history of China. It was published after his death by Desguignes, in 1771, at Paris. Gaubil published also a 'History of Genghis Khan and his Dynasty' (1739, Paris), which alone, according to the celebrated Chinese scholar Abel Remusat, would be sufficient to establish the reputation of the author. The other works of Gaubil are a 'Description of Peking,' and many essays on China and the adjacent countries, which are inserted in that celebrated collection published by the Jesuits under the title of 'Lettres curieuses et édifiantes,' which contains the description of the countries where they exercised their missionary labours. Gaubil died at Peking in 1759, aged seventy-one, after having resided in China thirty-six years. For further particulars the reader may consult the 31st vol. of the 'Lettres curieuses et édifiantes.'

* According to the treaty of 1728 between Russia and China, all the diplomatic correspondence between those two countries is carried on in Latin, Russian, and Mantchoo, and every despatch must be written in these three languages. A special school was established at Peking, in order to teach Russian to twenty young Mantchoos, who are afterwards placed either in the office for foreign affairs, or in offices on the frontier, where a knowledge of the Russian language is requisite. But notwithstanding all the efforts of the government to support that school, it is very far from being in a state of efficiency; and it is said that in 1805, when the Russian embassy came to Mongolia, the Chinese governor of that province called for some translators educated in the above-mentioned school. He expected to find in them able and trusty interpreters, without being obliged to apply to the Russians; but the first interview proved that he was mistaken. The Mantchoo interpreters confessed that they did not understand a word of what the Russians said, and they were sent back to Peking.

GAUDAMA, or GAUTAMA. [BUDDHA, vol. v., p. 527.]

GAUGING is the method of determining by actual measurement the number of gallons contained in any vessel intended to hold goods. The greatest use of this art is in the collection of the revenue, in which it is necessary to measure the bulk of vessels without disturbing their contents. For this purpose a number of rules have been laid down by various writers, of whom the reader who is interested in the subject may consult Leadbetter's 'Treatise on Gauging,' John Ward's 'Young Mathematician's Guide,' or Dr. Hutton's 'Mensuration.' The rules laid down were, in many cases, of uncertain application; as for instance, a close cask was to be treated either as a frustum of a spheroid, or of a parabolic spindle, or as a double frustum of a paraboloid, or else of a double cone, according to its appearance. The allowance made for the thickness of a cask was a guess, and the method of using *small* sliding-rules, to which supervisors formerly resorted to escape calculation, is a species of estimation which would never have been tolerated in money transactions between man and man. The inference to be drawn from the art as described by early writers, is that, generally speaking, the results of excisemen's measurements were below the truth: had it been otherwise, the fact could not but have been known to merchants and tradesmen, who can gauge their own vessels after the contents are removed, or who learn their bulk in the removal. If the methods of the excisemen were tolerably uniform, which is perhaps pretty nearly true, if we may judge from writers on the subject, no injustice was done by unequal taxation: and the government would probably have found it as easy to increase the duties, as to raise an additional revenue from a more correct method of collecting the old one.

With *larger* sliding-rules for calculation, and the aid of habit derived from experience, it is possible very accurately and easily to measure casks which do not depart much from a given standard of form. This is what is done by gaugers at the present time: and their practice has attained considerable accuracy. In a particular instance which has come to our knowledge, and in the case of a vat which held 6500 gallons, the measurement of the exciseman did not differ more than ten gallons from the truth. This degree of accuracy is entirely modern, and must in a considerable degree arise from similarity of form being very nearly preserved in the different species of casks.

The great variety of cases which occur would make a summary inconveniently long. Wherever a content is to be found, either the figure itself is simple and regular, as in the case of a cylinder, or nearly a simple figure, as in the case of some casks, which may be considered as the frusta of spheroids [See BARREL as an instance of the approximating supposition], or so irregular that the content can only be found by dividing them into a considerable number of sections, and considering each section as a small cylinder or frustum of a cone. [QUADRATURES, METHOD OF.]

The work on gauging, which is most commonly used, is Symon's 'Practical Gauger,' which has been through several editions. Other works are, those of Leadbetter, Shirtcliffe, Moss, Gutteridge, and Hey. The first three are of the first half of the last century, and that of Shirtcliffe contains theoretical investigations. Ward's 'Mathematician's Guide,' and Hutton's and Bonnycastle's 'Mensuration,' contain small treatises on the subject.

GAUL. [FRANCE.]

GAULNA. [CANDEISH, vol. vi., p. 233.]

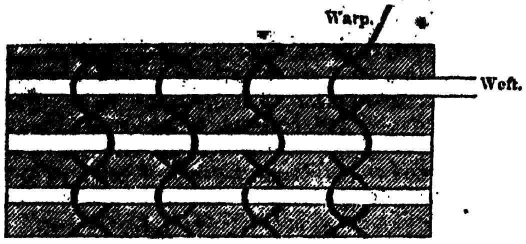
GAULS. [CELTÆ; FRANCE.]

GAURS. [GUEBRES.]

GAUZE, a light transparent texture, made of fine silken threads. Its name has led to the conjecture that this fabric was first invented in Gaza, a city of Palestine. Spitalfields was, some years back, the principal seat of the silk-gauze manufacture in Great Britain; but of late Paisley and Glasgow and their vicinities have almost entirely engrossed

this manufacture, and it is now nearly discontinued in London.

Gauze is one of the very few silken fabrics in the making of which the British manufacturer is still excelled by the French, both as to cheapness and quality. This cheapness results from the lower rate of wages paid to the French weavers as compared with ours; since the weight of silk contained in a yard of gauze is so trifling as to make the value of the material bear but a small proportion to that of the labour employed in its conversion.



The texture of gauze is different from that of plain weaving, in which the warp, or longitudinal threads, are always parallel to each other: the essential character of gauze-weaving is that between each cast of the shuttle a crossing of the warp threads shall ensue, and thus the weft (which forms the cross-threads interlaced by the warp) is not brought into absolute contact with the cross-thread immediately preceding. The intervals left between the interlacings cause that degree of transparency which, without such arrangement, could only result from a looseness of texture, incompatible with beauty and utility.

GAUZOU-POUCO, or Guazapuco Deer. [Deer, vol. viii., p. 361.]

GAVELKIND, a customary tenure existing at this day in the county of Kent only. It seems that this tenure was the common socage tenure among the Anglo-Saxons (Glanvil, l. 7, c. 3), and the reason of its continuance in Kent has been ascribed to the resistance which the inhabitants of the county made to the Norman invaders. This tenure also prevailed in Wales until the 34th Henry VIII., when it was abolished by statute. Various derivations of the term Gavelkind have been suggested: that adopted by Sir Edward Coke and his contemporaries was, *gave all kinde*, from the consequences of the tenure—an etymology worthy of Coke. But that generally received at the present day is from the Saxon *Gavel* (Rent); Gavelkind, that is, land of such a kind as to yield rent. A very elaborate examination of the several proposed derivations is given in the 1st chapter of Robinson's 'Treatise on Gavelkind.' The chief distinguishing properties of this tenure are: 'That upon the death of the owner without a will the land descends to all the sons in equal shares, and the issue of a deceased son, whether male or female, inherit his part; in default of sons, the land descends in equal shares to the daughters; in default of lineal heirs, the land goes to the brothers of the last holder; and in default of brothers, to their respective issue.'

The tenant may aliene at 15 years of age, by means of a feoffment [Feoffment], and the estate does not escheat in case of an attainder and execution, the maxim being, 'the father to the bough, the son to the plough.' The husband is tenant by curtesy of a moiety of his wife's lands, without having any issue by her; but if he marries again, not having issue, he forfeits his curtesy. A wife is endowed of a moiety of the lands of which her husband died seised, not for life as by the common law, but during chaste widowhood only. Gavelkind lands were generally devisable by will before the statute of wills was passed.

Several statutes have been passed, at the request of holders of Gavelkind lands, to render them descendible according to the course of the common law, or, as it is called, to disgavel them. These statutes however only alter the partible quality of the customary descent; they do not affect the other incidents to the tenure. And notwithstanding the extent of the disgavelling statutes, it is always presumed that lands in Kent are of this tenure, until the contrary is proved. The names of all the persons whose lands in Kent have been disgavelled may be found in Robinson's *Treatise*, before mentioned, p. 381. This was one of the tenures proposed to be abolished or modified by the Real Property Commissioners in their third Report. (2. Bl. *Com.*; Rob.'s *Gavelk.*)

This tenure existed also in Ireland as an incident to the custom of tanistry—and as such ceased with that custom in consequence of the judgment against it. (Davis's *Reports*, 28.) In the reign of Queen Anne, with the view of weakening the Roman Catholic interest in Ireland, the land of Roman Catholics was made descendible according to the custom of Gavelkind, unless the heir conformed within a limited time; but by the stat. 17 and 18 Geo. III., c. 49 (Irish), the lands of Catholics are made descendible according to the course of the common law. (Robinson, p. 21.)

This customary descent is followed in some manors, particularly in the manors of Stepney and Hackney. (See the custumal of those manors printed in 2 Watkins, *Copyh.*, 508.)

GAVIAL. [Crocodile, vol. viii., p. 167.]

GAVOT (*Gavotta*, Ital., *Gavotte*, Fr.), a lively dance of two strains, in duple time. This generally followed the minuet, and still succeeds the *Menuet de la Cour*, when the latter is introduced on the stage.

GAY, JOHN, a lively poet of the 18th century, born at or near Barnstaple, in Devonshire, in 1688, began the world as apprentice to a mercer in London. That employment however he soon forsook, and having published his first piece, 'Rural Sports,' in 1711, he dedicated it to Mr. Pope, and thus established an acquaintance which ripened into a firm and lasting friendship. In 1712 he became secretary to the Duchess of Monmouth, whose service he quitted in 1714, to attend the Earl of Clarendon, ambassador to Hanover, in a similar capacity. This was his introduction to a court life. He sought and obtained the favour of the Prince of Wales, but was neglected after that prince's accession to the throne: and the disappointment of his ambition he took so seriously to heart, that it appears to have had great effect in shortening his life. This was a great weakness, for Gay ought to have possessed in himself every requisite for comfort. His writings had been lucrative, and his wit, united with the simplicity and suavity of his temper, had secured to him a large circle of attached friends, both of the noble and the witty. But his spirits were easily elated and easily depressed; and an indolent improvident temper prevented him from making the best of the advantages which he possessed. The latter years of his life were spent in the household of the Duke of Queensberry, where he was treated with great kindness and respect. He died December 4, 1732, and was buried in Westminster Abbey, where a monument, with an affectionate inscription by Pope, is erected to him.

Gay wrote several comedies and farces, of which we need only mention a mock-heroic piece, the 'What d'ye call it,' which had a great run in 1715, and may still be read with amusement; and the celebrated 'Beggar's Opera,' which was brought on the stage in November, 1727, and was acted for 63 following days during that season, besides obtaining similar popularity in other places. The rest of his dramas have been long forgotten. His Fables, written with liveliness and elegance, are still popular with the young. The second part of them is of a political turn, and was written for the use of the infant Duke of Cumberland, in 1726. The 'Shepherd's Week' is a series of pastorals, written, it is said, in rivalry of Ambrose Philips, and representing rural life in its true character of poverty and rudeness, instead of in the false colours of romance. 'Trivia, or the Art of Walking the Streets of London,' shows talent for observation, and is a clever and spirited example of the mock-heroic. Of his minor pieces, the favourite ballad of 'Black Eyed Susan' is a good specimen. (Johnson's *Lives*; *Biog. Dict.*)

GAY-LUSSITE, a mineral so named in honour of the distinguished French chemist; it occurs in imbedded crystals; the primary form is a right-rhombic prism. Cleavage parallel to the lateral planes, distinct. Fracture conchoidal. Hardness 2·5. Very brittle and easily reduced to powder. Colour white or dirty white. Colour of the powder grey. Lustre vitreous. It is translucent or transparent, and doubly refractive. Specific gravity, 1·93 to 1·99.

It is slightly soluble in water; when heated it loses water; and before the blowpipe it fuses readily into an opaque globule, which has alkaline properties. Found in a thin stratum of soft clay covering a bed of sesquicarbonate of soda called *urao*, at the bottom of a lake near Lagunilla in Colombia.

Analysis according to Boussingault;—

Carbonic acid	28·66	
Soda	20·44	
Lime	17·70	
Water	32·20	
Alumina	1·

GAYA. [BAHAR.]

GAZA, now called Gazara, a town of Syria, or more properly speaking, of Palestine, on the S.W. frontiers of that country, near the borders of the desert which separates it from Egypt. It consists of the upper town, with a castle situated on a hill, about two miles from the sea, and a lower part, or suburb, in the valley below. The population is between 3000 and 4000. It has some manufactories of soap and cotton stuffs, and carries on some trade by sea, especially with Egypt, and also by land through the desert with Suez. Gaza is greatly fallen from its antient splendour; but it still exhibits signs of commercial activity and prosperity. It is repeatedly mentioned in Holy Writ, especially in Judges (c. xvi.), as one of the principal towns of the Philistines. It was besieged by Alexander the Great, and taken after an obstinate defence. It was afterwards destroyed by Alexander Jannæus, about 98 B.C., and forty years after was rebuilt by Gabinius, the Roman governor of Syria. The town was afterwards destroyed by the Jews in one of their revolts against the Romans; in the Acts of the Apostles (viii. 26), it is mentioned as being then deserted. It was however rebuilt, and is mentioned as a town of some consequence under Constantine, who gave it the name of Constantia. At a later period we find it mentioned in the wars of the Crusades. The traveller Sandys gives a good description of Gaza as it was towards the beginning of the 17th century, when there were still many remains of antient buildings, marble and granite pillars, &c. The hill upon which Gaza stands is about two miles in circumference at the base, and appears to have been once wholly enclosed by walls. The town being surrounded by gardens and plantations of olive and date trees, above which numerous and elegant minarets rise, has a pleasing appearance from a distance. The country around, which is hilly, is remarkably fertile. (Jolliffe's *Letters from Palestine*; Irby and Mangles' *Travels*; Richardson.)

GAZA, THEODORE, a learned Greek scholar, born at Thessalonica in the early part of the 15th century, emigrated to Italy, like others of his countrymen, at the time of the fall of the Eastern Empire. He found liberal patrons in his countryman Cardinal Bessarion, Pope Nicholas V., and King Alfonso of Naples. Gaza translated into Latin 'Aristotle's History of Animals;' the 'History of Plants,' by Theophrastus; the 'Aphorisms' of Hippocrates, and other Greek works. He also wrote a Greek Grammar, which was published at Rome in 1495, and was often reprinted. He was one of those who contributed powerfully to the revival of classical studies in Italy. Although he wrote in praise of Aristotle's opinions, and therefore on the same side as Georgius of Trebizond, in the then pending controversy concerning the comparative merits of Aristotle and Plato [BESSARION], yet his mildness and modesty kept him within the bounds of decorum, and he thereby became obnoxious to the more violent Georgius, who assailed him with invectives. Gaza died at Rome, or, as some say, in Calabria, at an advanced age. He wrote also a book on the 'Origin of the Turks,' and a treatise 'De Mensibus Atticis.'

GAZELLE. [ANTELOPE, vol. ii., p. 83.] Mr. Ogilby (1836) has elevated *Gazella* to the rank of a genus among his *Capridæ*; Type, *Gazella Dorcas*, *Antilope Dorcas* of authors. [GOAT.]

GAZETTE (*gazzetta* in Italian, *gaceta* in Spanish) is the name given to newspapers in several parts of the Continent. The name was, according to Ménage and others, derived from a small Italian coin, which was the price of the first newspaper established in that country. In England the London Gazette is an official newspaper, containing the proclamations, orders in council, promotions, bankruptcies, &c.

Gazetteer has been used in England to mean a geographical dictionary, such as Brookes' 'General Gazetteer,' and other similar works. [DICTIONARY.]

GEBERS. [GUEBRES.]

GEBHARDI, a German author, born in 1699 at Brunswick, died at Lüneburg in 1764. His most important work is a 'Universal Genealogy,' published in 1730-31, in German; it is divided into three volumes, each with a particular title; the first contains the pedigree of the sovereign houses of Europe which existed in 1731; the second, the pedigrees of the dynasties that were already extinct at that time; the third, the genealogy of Mohammedan and heathen monarchs. This production served as a basis to all the genealogical works published by the Germans during the eighteenth century. Gebhardi also wrote 'Historical and Genealogical Memoirs,' 3 vols., 8vo. His son published, after his father's death, a collection of materials for a genealogical history of the reigning families of Germany, which was left in manuscript by Gebhardi.

GE'BIA, GE'BIOS. [THALASSINA.]

GECARCI'NUS, Dr. Leach's generic name for those brachyurous decapod crustaceans known familiarly to the English as *Land-crabs*, and to the French by the appellations of *Tourlouroux*, *Crabes peintes*, or *Crabes violets*, some of these terms being applicable not only to different species, but to the same species at different ages, so that those various names cannot be depended upon as specific designations.

Latreille placed this tribe of crabs immediately after *Pinnotheres*. He seems to admit *Plagusia* and *Grapsus* into the same section with the Land-crabs, properly so called; and next to *Grapsus* come the *Orbiculata* (his fourth section), containing *Corystes*, &c.

Desmarest places *Gecarcinus* at the head of the *Quadrilatères* of Latreille, and arranges all the true Land-crabs under that generic title, which is preceded by *Pilumnus*, and succeeded by the *Orbiculata* of Latreille.

M. Milne Edwards makes the *Gecarcinians* the second tribe of his family of *Catametopes*; and in his arrangement they stand between the *Thelphusians*, the first tribe, and the *Pinnotherians*, the second tribe of that family.

According to the last-named author the tribe of *Gecarcinians* is one of the most remarkable groups of the class *Crustacea*; for it is composed of animals breathing by means of branchiæ, or gills, and yet essentially terrestrial, so much so indeed, that they would perish from asphyxia if submerged for any length of time. They may be distinguished easily from the rest of the family by their nearly oval carapace, which is much elevated and convex above. The branchial regions are in general very distinct, and project much below, occupying nearly two-thirds of the surface. The front is very nearly as large as the buccal frame (*cadre buccal*), and strongly curved below. The orbits are suboval, moderate, and very deep. The lateral borders of the carapace are very much arched, and generally describe a semicircle. The *internal antennæ* are lodged under the front, and fold back transversely in narrow and often nearly linear excavations. The disposition of the external antennæ varies, and so do the jaw-feet (*pates-mâchoires*); sometimes the fourth joint is inserted at the external angle of the preceding, and remains exposed, as in the *Ocypodians*, and sometimes it is entirely hidden under its internal surface. The *feet* of the first pair are long and strong; the succeeding feet are robust and long, and very nearly equal in size, and their tarsus is pointed and quadrilateral. The *abdomen* of the *male* is received in a deep excavation of the sternal *plastron*, and its second articulation reaches nearly always to the base of the posterior feet. It is in general so long that it comes up to the base of the mouth, and the appendages hidden beneath it are remarkably large. The branchiæ are generally seven in number, viz., five fixed to the vault of the sides, and two, in a rudimentary state, hidden under the base of the preceding, and taking their origin from the jaw-feet; but in some species there are nine on each side. The respiratory cavity is very large, and is raised into a vault highly elevated above the branchiæ, so that above those organs there is a large empty space. The tegumentary membrane with which it is lined is also very spongy, and sometimes forms a fold along the lower edge of the cavity, so as to form a kind of gutter, or longitudinal trough for containing water when the animal remains exposed to the air. (Milne Edwards.) Observations on this curious reservoir were communicated to the Royal Academy of Sciences in France by MM. Audouin and Milne Edwards some years ago, wherein the authors show that in all the crustacea the branchiæ are fitted to perform the functions of respiratory organs in the air as well as in the water; that the more or less rapid death of the aquatic species, when exposed to the air, depends upon various causes, of which one of the most direct is the evaporation from the

branchiæ, which produces their desiccation; that consequently one of the conditions necessary to the support of life in animals which have branchiæ, and live in the air, is the having these organs defended against desiccation; and lastly, that these dispositions actually occur in the Land-crabs, which all possess various organs destined for absorbing and keeping in reserve the quantity of moisture necessary for maintaining a suitable degree of moisture in the branchiæ.*

Geographical Distribution, Habits, Reproduction, &c.—The Land-crabs, or Gecarcinians, inhabit the warm countries of the New and Old World, and Australasia; but as far as observation has hitherto gone, America and its islands seem to be the places where the form is most highly and most numerously developed. Almost every writer on the Natural History of the countries last mentioned treats largely on the habits of these creatures, and in the works of Rochefort (*Histoire Naturelle des Antilles*), De Feuillée (*Observations faites sur les Côtes d'Amerique*), De Labat (*Nouveau Voyage aux Isles d'Amerique*), Sloane (*Natural History of Jamaica*), Browne (*Civil and Natural History of Jamaica*), Hughes (*Natural History of Barbados*), Catesby (*Natural History of Carolina*), &c. &c., will be found details more or less ample, and highly interesting, of their manners; though most of the writers do not determine the species sufficiently to enable us to judge of what particular Land-crab they are writing. All these authors will however well repay the trouble of consulting them.

Latreille sums up what he considers the credible parts of these narratives thus:—The crabs pass the greatest part of their life on land, hiding themselves in holes, and not coming forth till evening. Some keep about cemeteries. Once a year, when they would lay their eggs, they assemble in numerous bands, and move in the shortest direction to the sea, without caring for any obstacles. After they have finished their deposit they return much weakened. It is said that they block up their burrows during their moult; and while they are undergoing this operation, and are still soft, they are called *Boursiers* (Purse-crabs), and their flesh is then much esteemed, although it is sometimes poisonous. This quality is attributed to the fruit of the manchineel, of which the people think, falsely perhaps, that the crabs have eaten.

The reader will find under the article BIRGUS some extracts giving an account of the moulting of the Land-crabs, and showing that they are then called *Crabes Boursières*, in the attempt to point out that Linnæus was misled in supposing the true Purse-crabs to be inhabitants of the Antilles, on the authority of Rochefort (vol. iv., p. 433). With regard to the alleged want of foundation for the story of the Land-crabs being sometimes poisonous, in consequence of what they have eaten, there are so many testimonies to the fact, that it will be a fault on the right side to be cautious. Thus Sloane, who praises (as who does not?) their delicacy of taste, says, 'They are thought to be poysonous when they feed on the Mansanilla-tree leaves or fruit, which I suppose may come from some of it sticking to their chaps, or lying undigested in their stomachs, which are not separated before eating.' Catesby writes, 'Some are black, some yellow, some red, and others variegated with red, white and yellow mixed. Some of these, as well as of the fish of this country, are poisonous: of which several people have died, particularly of the black kind: the light coloured are reckoned best, and when full in flesh are very well tasted. In some of the sugar islands they are eat without danger, and are no small help to the negro slaves, who on many of the islands would fare very ill without them. They feed on vegetables.' Hughes, speaking of the 'large white land-crab,' and its feeding on grass, &c., remarks, 'They likewise often feed upon manchineel apples, as well as upon the leaves or berries of poison-trees. At such times they are dangerous to be eaten, unless very great care be taken to wash the fat, as well as the other meat on the inside, with lime-juice and water.' He says the same in effect of 'the Mulatto Crab.'

M. Milne Edwards thus gives his summary:—The greater number ordinarily haunt humid places, and hide themselves in holes which they excavate in the earth, but the localities preferred by them vary with the species. Some live in the low and marshy lands near the sea, others on the wooded hills far from the shore; and at certain epochs, these last quit their habitual dwelling to go to the sea. It is even reported that then these crustaceans unite in great bands and thus make very long journeys without suffering themselves to be stopped by any obstacle, and laying waste everything in their route. Their principal food consists of vegetable substances, and they are nocturnal or crepuscular in their habits. It is more particularly in the rainy season that they quit their burrows, and they run with great rapidity. It would appear that it is at the time of laying that they go to the sea and there deposit their eggs, but we know of no decidedly positive observation on this point. During their moult they remain hidden in their burrows. (*Hist. Nat. des Crustacés.*)

We select Browne's account of the habits of the 'black or mountain crab' (*Cancer Ruricola*, Linn.), because he resided many years in the Island of Jamaica, and seems to have lost no opportunity of making personal observations. 'These creatures are very numerous in some parts of Jamaica, as well as in the neighbouring islands, and on the coast of the main continent; they are generally of a dark purple colour, but this often varies, and you frequently find them spotted, or entirely of another hue. They live chiefly on dry land, and at a considerable distance from the sea, which however they visit once a year to wash off their spawn, and afterwards return to the woods and higher lands, where they continue for the remaining part of the season; nor do the young ones ever fail to follow them as soon as they are able to crawl. The old crabs generally regain their habitations in the mountains, which are seldom within less than a mile, and not often above three from the shore, by the latter end of June, and then provide themselves with convenient burrows, in which they pass the greatest part of the day, going out only at night to feed. In December and January they begin to be in spawn, and are then very fat and delicate, but continue to grow richer until the month of May, which is the season for them to wash off their eggs. They begin to move down in February, and are very much abroad in March and April, which seems to be the time for the impregnation of their eggs, being then frequently found fixed together; but the males about this time begin to lose their flavour and richness of their juices. The eggs are discharged from the body through two small round holes situated at the sides, and about the middle of the under shell; these are only large enough to admit one at a time, and as they pass they are entangled in the branched capillaments, with which the under side of the apron is copiously supplied, to which they stick by the means of their proper gluten, until the creatures reach the surf, where they wash them all off, and then they begin to return back again to the mountains. It is remarkable that the bag or stomach of this creature changes its juices with the state of the body; and while poor is full of a black, bitter, disagreeable fluid, which diminishes as it fattens, and at length acquires a delicate rich flavour. About the month of July or August the crabs fatten again and prepare for mouldering, filling up their burrows with dry grass, leaves, and abundance of other materials: when the proper period comes each retires to his hole, shuts up the passage, and remains quite inactive until he gets rid of his old shell and is fully provided with a new one. How long they continue in this state is uncertain, but the shell is observed to burst both at the back and sides to give a passage to the body, and it extracts its limbs from all the other parts gradually afterward. At this time the fish is in the richest state, and covered only with a tender membranous skin, variegated with a multitude of reddish veins, but this hardens gradually after, and becomes soon a perfect shell like the former; it is however remarkable that during this change there are some stony concretions always formed in the bag, which waste and dissolve gradually as the creature forms and perfects its new crust. A wonderful mechanism! This crab runs very fast, and always endeavours to get into some hole or crevice on the approach of danger; nor does it wholly depend on its art and swiftness, for while it retreats it keeps both claws expanded, ready to catch the offender if he should come within its reach, and if it succeeds on these occasions it commonly throws off the claw, which continues to squeeze with incredible force for near a minute after; while he, regardless of the loss, endeavours to make his escape and to gain a more secure or a more lonely covert, contented to renew his limb with his coat at the ensuing change; nor would it grudge to lose many of the others to preserve the trunk entire, though each comes

* 'De la Respiration aérienne des Crustacés, et des modifications que l'appareil branchial éprouve dans les crabes terrestres.'

off with more labour and reluctance, as their numbers lessen.'

Thus much of the habits of the Land-crabs of the New World. The late bishop Heber in his 'Narrative' gives an account of some Land-crabs in India, living at a great distance from the sea, and obstructed by great obstacles in their passage to it. 'The plain of Poonah,' writes the Bishop, 'is very bare of trees, and though there are some gardens immediately around the city, yet as both these and the city itself lie in a small hollow on the banks of the river Moola, they are not sufficiently conspicuous to interrupt the general character of nakedness in the picture, any more than the few young trees and ornamented shrubs with which the bungalows of the cantonment are intermingled. The principal and most pleasing feature is a small insulated hill immediately over the town, with a temple of the goddess Parvati on its summit, and a large tank (which, when I saw it, was nearly dry) at its base. All the grass-land round this tank, and generally through the Deckan, swarms with a small land-crab, which burrows in the ground, and runs with considerable swiftness, even when encumbered with a bundle of food almost as big as itself. This food is grass, or the green stalks of rice, and it is amusing to see them sitting as it were upright, to cut their hay with their sharp pincers, then waddling off with the sheaf to their holes as quickly as their sidelong pace will carry them.' Upon this passage Mr. Broderip observes, that when we call to mind the position of Poonah, and read of the neighbouring river and tank, we may feel inclined to ask whether the river or the tank might not be the scene of ovipositing; and, he adds, that it is not improbable that there may be a race of land-crabs appropriated to continental or even insular situations out of reach of the ocean, and that fresh water may be as necessary to their reproduction as sea water is to the land-crabs of the West Indies. Such a supposition, he thinks, is in unison with the bountiful provisions of nature for the general diffusion of animal life. (*Zool. Journal*, vol. iv.)

Mr. Westwood in his interesting paper 'On the supposed existence of Metamorphoses in the Crustacea' (*Phil. Trans.*, 1835), notices the abdomens of several female crabs having the interior surface covered with hundreds of eggs or newly-hatched young, which were in the collection of the late Rev. Lansdown Guilding. One of the bottles in which one of these was deposited was labelled by the last-mentioned gentleman, 'Eggs and young of a Land-crab not undergoing Metamorphosis.' From this specimen Mr. Westwood obtained eggs, and young crabs evidently just hatched, and others at a rather later stage of their growth. The eggs were of a dark-reddish colour, showing through the outer integument the rudimental limbs of a future animal of a paler colour. On removing the thin transparent pellicle which surrounded one of these eggs, the eyes were most conspicuous, the tail was seen extended as a narrow plate, nearly reaching to the eyes, and along its sides lay the large anterior cheliferous, and the four following simple pairs of limbs. The existing organs, although perfectly discernible, occupied only a small portion of one side of the egg, its greater part being filled with hardened matter composed of minute molecular grains. The animal was in a sufficiently forward state of development not to allow the least doubt to be entertained as to the nature of these limbs, nor did any organs appear answering to the two large split pairs of natatory organs of *Zoëa*. The branchiæ, in a fleshy and unorganized state, were also found at the base of the legs. The eggs were 1½ lines in diameter.

Mr. Westwood gives in his Memoir figures of the egg, and of the young crab in progressive stages of growth. His reputation as an observer is too well founded to allow a doubt of the accuracy of his illustrations and description; and though, it is true, the Rev. Mr. Guilding does not state the species, that lamented gentleman's acquirements are too well known to suppose it possible that he should have mistaken the tribe. Indeed, the subject of the reproduction of Land-crabs was one most likely to attract the attention of a naturalist who devoted so much of his attention to the zoology of the Caribean Islands, and resided so long in one of them. Mr. Westwood's observations, then, appear to embody a conclusive answer to the arguments adduced by Mr. Thompson from the habits of the West Indian Land-crabs; for they show that one species, at least, does not undergo metamorphosis.

Utility to man.—As an article of food some of the Land-crabs, when in season and well nourished, may be considered as combining the qualities of wholesomeness and delicious flavour. We have conversed with men of various tastes who have partaken of this luxurious food, and all agree in describing it as exquisite. Indeed it appears that when simply cooked in its own juices, in its own shell, it requires no condiment but a squeeze of the fragrant lime to make it one of the best of dishes. 'When the black crab (*Gecarcinus Ruricola*) is fat,' says Dr. Patrick Browne, 'and in a perfect state, it surpasses everything of the sort in flavour and delicacy; and frequently joins a little of the bitter with its native richness, which renders it not only more agreeable in general, but makes it sit extremely easy upon the stomach. They are frequently boiled and served up whole; but are commonly stewed when served up at the more sumptuous tables.' Land-crabs have been brought alive to this country. We saw one or two in apparently good health, running about in the Zoological Gardens in the Regent's Park. They were, as well as we recollect, of the species last named, and came from the West Indies. The suggestion may be rather hard upon the West Indians; but why, may we ask, are not these crabs imported for our tables as regularly as turtle? Barrels with grass and other vegetables, such as they are generally kept in, when there is no better convenience, in their native country, would not take much room on deck; and if the crabs were collected at the proper time and allowed sufficient moisture and only sufficient to keep them in health, an ordinary voyage would bring them to us, most probably, in very fair condition.

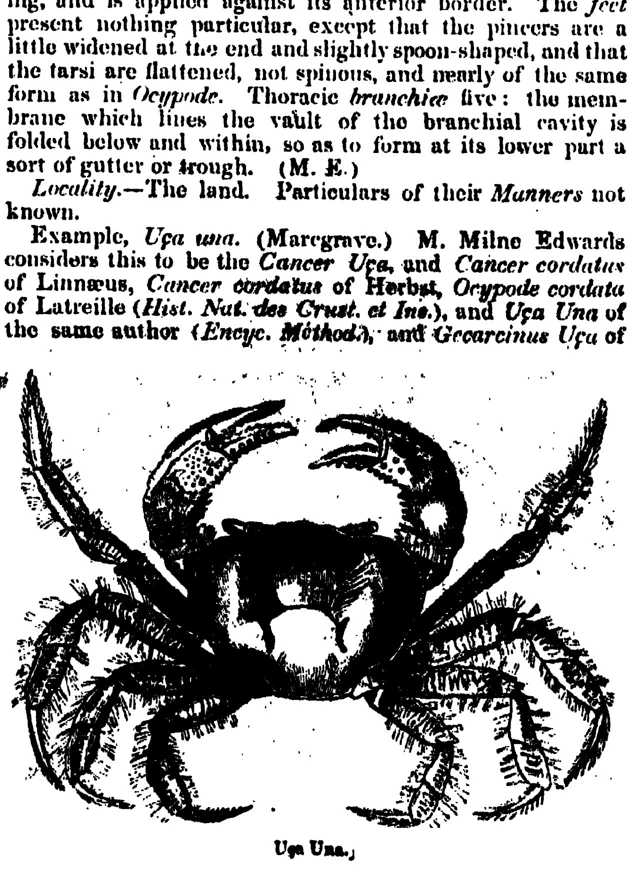
M. Milne Edwards separates the Gecarcinians into the following genera:—

Uça. (Latreille.)

Generic Character.—*Carapace* much wider than it is long, of a suboval shape, and very much elevated. *Front* narrower than in the other Gecarcinians, very much inclined and nearly semicircular. *Orbits* rather large, and open externally below their external angle. *Anterior fossettes* suboval, small, and separated by a small triangular prolongation from the epistome. The *external antenna* occupies the orbitary internal canthus. The *buccal frame* is of a rhomboïdal form. The second and third joint of the *external jaw-feet* are quadrilateral, nearly of the same size, and terminate on the internal side by a straight border. The fourth joint is inserted at the external angle of the preceding, and is applied against its anterior border. The *feet* present nothing particular, except that the pincers are a little widened at the end and slightly spoon-shaped, and that the tarsi are flattened, not spinous, and nearly of the same form as in *Ocypode*. Thoracic *branchiæ* five: the membrane which lines the vault of the branchial cavity is folded below and within, so as to form at its lower part a sort of gutter or trough. (M. E.)

Locality.—The land. Particulars of their *Manners* not known.

Example, *Uça una.* (Marcgrave.) M. Milne Edwards considers this to be the *Cancer Uça*, and *Cancer cordatus* of Linnæus, *Cancer cordatus* of Herbst, *Ocypode cordata* of Latreille (*Hist. Nat. des Crust. et Ins.*), and *Uça Una* of the same author (*Encyc. Méthod.*), and *Gecarcinus Uça* of



Uça Una.

Lamarck. He observes, that M. Latreille cites his *Ocypode fossor* as one of the synonymes of *Uça Una*, but that he (M. Milne E.) is inclined to believe that it is rather referrible to *Uça lævis*.

Description of *Uça Una*.—Lateral edges of the *carapace* furnished with a small projecting and finely dentilated crest. *Pterygostomian regions* very granulous. *Manus* spiny above and within. *Feet* hairy below, moderate in length; the third pair rather longer than the others. Size two inches (French). *Locality*, South America.

Cardisoma. (Latreille.)

Generic character.—*Carapace* more elevated and square than in the greater part of the same tribe. *Buccal frame* in the shape of a long squared figure, with its lateral edges straight. The second joint of the *external jaw-feet* narrowed anteriorly, and the third, which is a little shorter than the preceding, widening from behind forwards, so that these organs leave between them, in the middle of the buccal apparatus, a wide space with nearly the form of a lozenge; the third joint, which is nearly cordiform, is notched on its anterior border and gives insertion at its external angle to the fourth joint, which like the succeeding ones always remains exposed. *Front* very large and nearly straight. *Antennary fossettes* transversal and separated by a semicircular and very wide surface. *Feet* of the third and fourth pairs longest; the *tarsi* quadrilateral and very spiny. *Branchiæ* placed under the vault of the sides, seven on each side, the first being ordinarily very small and the two last very long.

Locality; Habits.—The species of this genus live in the woods and dig deep and oblique holes whence they come not forth except at night. (M. E.)

Example, *Cardisoma Carnifex.*—This, according to M. Milne Edwards, is the *Cancer Carnifex* of Herbst; *Ocypode cordata*, *Gecarcinus Carnifex*, and *Cardisoma Carnifex* of Latreille, and he cites also *Gecarcinus hirtipes* of Lamarck, as a synonyme, but with a query.

Description of *Cardisoma Carnifex.*—Carapace very much elevated and its surface very much curved from before backwards, but nearly horizontal transversely: its lateral edges marked by a projecting and elevated line. A small tooth behind the external orbitary angle. Four rows of spines upon the *tarsi*; the two lower not numerous. *Pincers* large on one side; *Manus* very large; *fingers* touching nearly throughout their length. Length two inches (French). (M. E.)

Locality.—The neighbourhood of Pondicherry.

Cardisoma Carnifex.

Cancer Hydromus of Herbst, in the opinion of M. Milne Edwards, is evidently a species approximating closely to the preceding, if indeed it can be distinguished from it.

Cardisoma Guanhumi, which inhabits the Antilles, is more than three inches in length, and the claws of the male are larger than the body, very much curved, and not touching except at their extremity.

Gecarcoïdea.

Carapace more oval and less elevated than in the preceding genera. *Front* of moderate length, straight, and very much inclined. *Antennary fossettes* rounded and separated by a small triangular prolongation of the front. *Orbits* small; their inferior border much less projecting than in the preceding genera, and leaving between its internal angle and the external antenna a large and deep notch. *Buccal frame* not so clearly circumscribed as ordinarily, and rather circular than square. *External jaw-feet* with a wide space between them; their third joint much less than the second, nearly quadrilateral, little or not at all narrowed backwards, and deeply notched at its anterior edge, at the middle of which is inserted the succeeding joint, which is exposed.

Example, *Gecarcoidea Lalandii.*—Carapace inclining to oval and without a crest on its lateral edges. Feet strong; pincers large, cylindrical, tuberculous, and touching throughout their length; anterior edge of the arms nodulous; succeeding feet dentilated on the edges, those of the third pair the longest. Six rows of dentations on the tarsi. Colour brownish-red. Length rather more than three inches. (M.E.)

Locality, Brazil.

Gecarcinus.

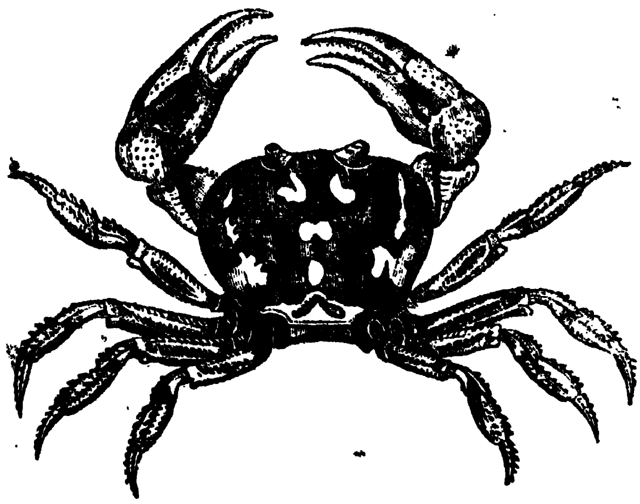
Carapace not much elevated, but very convex on the sides. *Front* very strongly curved below. *Orbits* deep, inclining to oval, and without a notch on the external side. *Internal Antennæ* nearly hidden under the front, which has a small prolongation that goes to join the epistome. The disposition of the *external antennæ* and that of the canthus of the orbit nearly the same as in the preceding genus. *Buccal frame* nearly circular and not clearly separated from the pterygostomian regions. *External jaw-feet* very wide, but with a space between them; their second joint completely covers the succeeding joints, which are inserted on its internal surface. The external appendage of these organs is hidden under their second joint and its extremity scarcely overpasses it. *Feet* presenting nothing remarkable, excepting that their edges are armed with spiniform teeth.

Localities.—The Antilles; Australasia.

Example, *Gecarcinus Ruricola*; *Cancer Terrestris*, Seba; *Cancer Ruricola*, Linn.; *The Land-Crab*, Sloane; *The Black* or *Mountain-Crab*, Browne; *Crabe violet ?* Labat.

Description.—Tarsi armed with six rows of spiniform teeth. Internal edge of the third joint of the jaw-feet without any remarkable fissure. Carapace very large. A few teeth on the internal edge of the carpus. Length rather more than three inches. Colour purplish or reddish-violet, or yellow washed with red. (M. E.)

Locality, the Antilles.



Gecarcinus Ruricola.

Fossil Gecarcinians?

M. Desmarest, in his *Histoire Naturelle des Crustacés fossiles*, describes and figures a species which he notices as being sufficiently common in collections, under the name of *Gecarcinus trispinosus*. The same author, in his *Considérations Générales sur la classe des Crustacés*, alludes to this figure and description, and observes that he has arranged the fossil, with doubt, under the genus *Gecarcinus*. M. Milne Edwards (*Histoire Naturelle des Crustacés*) expresses his belief that this fossil is not a Gecarcinian, and says that it would appear, from the form of the carapace, to approximate more to the genus *Pseudograpsus*.

GECKO, GECKO-FAMILY, GECKOTIDÆ, a natural family of Saurians.

Their head is wide and flattened, with the mouth wide; the nostrils are distinct and lateral; the eyes large, hardly surrounded by short lids, the lower edge of which in the greater number of species does not project outwards, the pupil sometimes rounded, but most frequently dentilated, linear, and lightly fringed; and the auditory opening bordered with two folds of the skin. The teeth are small, equal, compressed, sharp at the point, entire, and planted in the internal edge of the jaws: there are none on the palate. The tongue is short, fleshy, capable of but little elongation, and free at its extremity, which is either rounded or flattened, or very slightly notched.

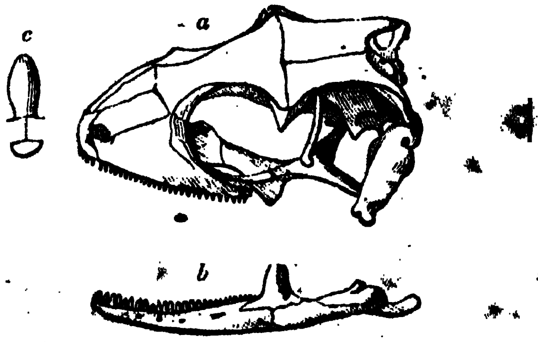
Their neck is apparently little, in consequence of the width of the back part of the head and the squareness of the shoulders. Their body is thick and short, depressed, and low on the legs, with a belly flat below, dragging on the ground, and largest in the middle. There is no crest on the back. The tail varies, but is not long, and often has folds or circular depressions, but never a dorsal crest.

The feet are short, nearly equal in length, wide apart, and robust; the toes nearly equally long, most frequently flattened below, widened, and furnished with transverse, imbricated plates; the nails vary, but they are ordinarily hooked, sharp, and retractile. The conformation of the feet enables the Geckos to run with ease on the smoothest surfaces in every direction, or to remain stationary on them with the back downwards, after the manner of a common house-fly.

The skin is defended by equal granular scales, most frequently interspersed with other tubercular scales, the points blunt or angular. There are femoral pores or pores in front of the vent, on the same line in the majority of species, and, most frequently, in the males only. The limbs and sides are sometimes bordered with fringed membranes.

Organization.

Skeleton.—The skull of the Geckotidæ is marked by some peculiar characters. The bones are well defined, nor do the sutures seem to be obliterated by age. In general contour it approaches the skull of the *Crocodilidæ* by its width, its flatness, and its length; its particular resemblances to the same part in that family are to be found in the disposition of the orbits and in the articulation of the jaws. The excavations for the eyes are very large and apparently incomplete, inasmuch as the orbital frame is not entirely bony in its back part, nor has it, so to speak, any flooring, so that when deprived of the softer parts the cavity communicates with the mouth. The articulation of the jaw is quite backwards, and the *os quadratum* or interarticular bone is wide, short, and hollowed on its posterior surface, for the purpose of receiving the muscle whose office it is to open the jaws and keep them open. The skull differs from that of the other lizards generally in the extreme smallness of the jugal and temporal bones, and in having the parietal bones divided longitudinally into two.



Skull of Gecko: *a*, cranium; *b*, lower jaw; *c*, a tooth enlarged. (Cuv. Oss. Foss.)

The vertebræ vary in number, and, according to Meckel, their body is hollowed into two conical cavities, very nearly like those of fishes: the spinal column is without any spinous processes or projections. The three or four first cervical vertebræ only are without false ribs or transverse articulated apophyses. These are gradually developed, and go on increasing in length and curvature to the fifth or seventh, but none of them are actually joined to the great anterior portion of the sternum. Those which follow reach and are articulated with that bone. They are succeeded by the free or abdominal ribs, which nearly equal in number the vertebræ which precede the pelvis, at least in the *Banded Gecko*.

The sternum in the *Common Gecko* (*Platydactylus guttatus* of Cuvier; *Gecko verus* of Merrem and Gray) consists of a very solid plate, which receives anteriorly and laterally in two angular notches the coracoïd bones, which are wide and delicate, and the clavicles, which are narrow, elongated, and flattened, more especially at their sternal extremity. The rhomboïd and backward portion of this sternal plate affords attachment on the two posterior facings to three pairs of ribs. From the posterior or abdominal angle of this bone two small parallel bones or sternal prolongations are given off, along which three other pairs of ribs are affixed by ligaments. After these six pairs of sternal ribs come seven other pairs, which are curved at their free or abdominal extremity into an obtuse angle, so that they are at this end directed forwards without any junction to a mesial line as in the Chameleons. M. Duméril says that generally he has only counted seventeen ribs; but he observes that there are twenty-four in the *Banded Gecko* (*Platydactylus vittatus* of Cuvier; *Gecko vittatus* of authors). Hence M. Duméril concludes that the number of ribs varies according to the species.

The caudal and pelvic vertebræ require notice. The articulation of the former is either weak, or the body of the vertebra itself is apt to break in the middle, so that a slight effort separates them, and many individuals consequently lose their tails. When these are regenerated, cartilage is generally found in the place of the former bone, and the tail then presents a variety of forms.

The bones of the limbs do not differ from those of the other Saurians so as to require any particular description, with the exception of those of the feet, and there the difference is striking with relation to the greater portion of the class. In the Geckotidæ the bones of the feet are so disposed as to receive the five toes of equal or nearly equal length, and which radiate as it were from a centre so as to form a nearly complete circle; for the external or great toe cannot separate itself from the others to extend itself backwards. The toes are not always furnished with nails; but they are often provided with very remarkable ones, which by their mobility and retractility remind the observer of the organization of the same parts in the cats (*Felidæ*).

Muscular System principally as relating to Locomotion.—The muscles of the *Geckotidæ* are highly irritable, as might be expected in such nimble creatures. Their power of adhering to smooth surfaces makes it necessary that the resistance produced by the adhesion should be instantaneously overcome in case of danger; and we accordingly find that a Gecko which at one moment is fixed motionless to a spot, vanishes as it were in the next from under the hand stretched forth to capture it.

Brain, Nervous System, and Senses.—The brain and nervous system are considerably developed in the *Geckotidæ*, and the greater part of the senses are acute.

Sight.—The orbits, as we have seen, are large and without any flooring or base, and as the eye in this family is very large in proportion to the size of the animal, the projection of the posterior part of the globe may be seen in the inside of the mouth much in the same way as is observable in some fishes. There is scarcely any lid, and what there is is so small that an additional appearance of prominence is given to the eyeball. This lid is simple, circular, and adherent to the globe of the eye by an internal fold. There is a nictitating membrane. Most persons have seen that an epidermic scale which seems to be the external layer of the cornea comes off in serpents with the rest of the skin, and in the Geckos also the integument passes over the front of the eyeball. The eye in such animals never appears humid. M. Jules Cloquet has shown that in the serpents the tears probably are diffused between the epidermic scale and cornea in order to arrive at the nostrils. The pupil is sometimes rounded, but most frequently presents a linear slit, the edges of which are fringed, so that the animal can at its pleasure dilate or diminish the opening through which the light and the images are to be admitted to the retina. Like the cats therefore, the Geckos, though said to be nocturnal in their habits, can also see perfectly well in broad daylight.

Hearing.—The auditory apertures in this family are some

times in the form of slits, sometimes in that of oval or circular holes, and the edges are often rounded and sometimes dentilated. Wagler states that these apertures can be closed in *Ptyodactylus* and *Spheriodactylus*, and it is extremely probable that the rims have a power of approximation generally. The tympanum lies deep, and the auditory cavity communicates with the back of the mouth or throat for the admission of air, as in most pulmoniferous animals. M. Duméril says, that he has proved the sensibility of these animals to the least noises, and that their sense of hearing is very fine.

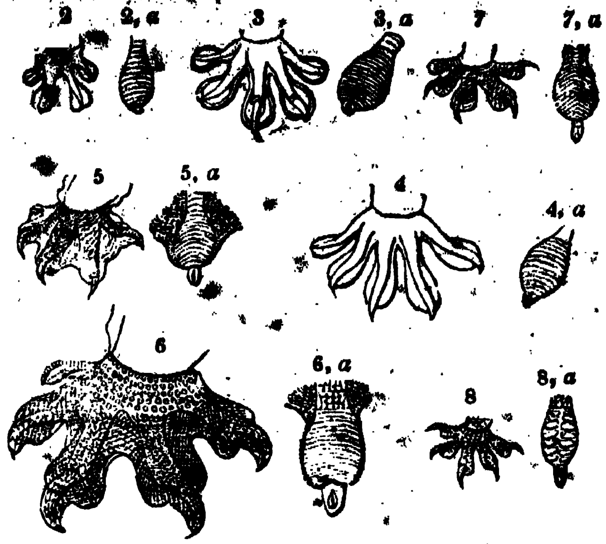
Smell.—The structure of the nostrils in this family would not lead to the conclusion that their sense of smelling is very acute, though it is probably more highly developed than it is in the Frogs.

Taste.—The *Geckotidæ* swallow their prey living, or nearly so, and almost entire, but the presence and form of the teeth render it probable that they can masticate; and this power, combined as it is with the form and structure of the tongue, which is soft, moveable, very fleshy, and furnished with papillæ, seems to indicate a certain degree of the sense of taste.

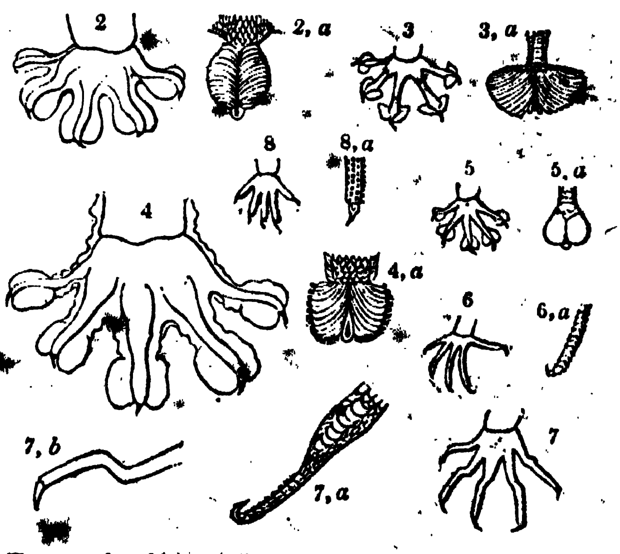
Touch and Integuments.—The skin of the Geckos is generally delicate, and adheres but little to the muscles, from which it is easily detached. In the middle of the back, and sometimes on the sides, granular tubercles rounded on their edges, with others which project at the centre, and are even fashioned into facets, are to be detected in the greater number. When the skin is detached and held up to the light it is seen to be regularly furnished with small delicate, rounded, escutcheon-like bodies, set in the thickness of the skin. The form and distribution of these bodies vary according to the different species in the regions of the belly, of the neck, of the thighs, of the head, and of the tail. M. Duméril, who gives us this information, goes on to state that generally the skin of the *Geckotidæ* is grey or yellowish, but that there are species in which lively colours are disposed on some parts of their bodies, and that it is even said that tints of red, blue, and yellow may be distinguished, which the animal causes to appear and disappear nearly after the manner of the chameleons. Some travellers assured Wagler that certain Indian Geckos became luminous or phosphorescent during the night.

In some of the species the skin is prolonged on the sides of the body and tail into membranes regularly festooned or fringed, and the Geckos generally moult or change their skins at certain periods of the year, when their colours, as is usual in such cases, become brighter. M. Duméril says that he has himself observed this in living individuals captured in their wild state at Cordova, in Spain, in the middle of the summer. There can be little doubt that there is considerable sensibility where the skin is constructed as it is in the Geckos; but, in considering the sense of touch, the curious organization of the feet and toes demands our particular attention. These are the great organs of station or fixation and progression, and the manner in which they perform their office is very interesting. M. Duméril, after referring to Wagler's reflections on this subject in his remarks on the *Platyglossi*, gives his own observations on this part of the organization of the Geckos. He refers to the comparative shortness and general structure of the feet above given, and then proceeds to notice the particular conformation of the toes in the greatest number of species. The lower surface of these, and the sole, are very much dilated, widened, and furnished with small plates or lamellæ, following or overlying each other (lamelles placées en recouvrement) in a regular manner, but in a mode which varies in the different species. The nails, which are sometimes wanting on all the toes, are most frequently pointed, hooked, and more or less retractile, constituting a sort of claws, which remain constantly sharp. The toes are sometimes united at their base, and, as it were, semipalmated. In some of the species, *Ptyodactylus* and *Spheriodactylus* of Cuvier, for instance, the extremity of the toes expands, and widens considerably in form of a fan or semi-disk, as in the Tree-frogs. The same author then alludes to the organization of the feet in certain insects, particularly the *Orthoptera* and *Diptera*, which enables them to maintain an inverted position.

The membranous and soft plates with which the lower surface of the toes of the Geckos are furnished present a variety of modifications in the different genera. Sometimes they are simple, or continued from one edge to the other, and those of this class offer distinctions in the furrows themselves, and in the curves described by the lines which mark them; sometimes they are separated longitudinally by a groove, sometimes they are complete or continued throughout the length, sometimes they exist on the last phalanges only; and, lastly, in the aberrant genera they are hardly distinct. The modifications of this curious apparatus, as well as the absence or presence of the nails, afford the leading characters on which Herpetologists have established the different genera, and we here present the various forms collected by M. Duméril.



Feet and structure of the under part of the toes of *Geckotidæ*. The figure marked with the numeral only, represents the foot; the figure marked with the added letter *a*, represents the structure of the lower part of the toe. 2, Platydactylus Cepedianus; 3, Platydactylus Ægyptiacus; 4, Platydactylus guttatus (Gecko verus, Common Gecko, of Gray); 5, Platydactylus homalocephalus (Ptychozoon, of Kuhl; Pteropleura, of Gray): 6, Platydactylus Leachianus (Ascalabotes Leachianus; Griff., 'Anim. King.'); 7, Hemidactylus Oualensis (Peropus of Wiegmann); 8, Hemidactylus triedrus.



The numerals and letters indicate the same parts as they do in the upper figure, with the exception of 7, *b*, which represents a claw in profile. 2, Thecodactylus Theconyx; 3, Ptyodactylus Hasselquistii (P. guttatus, of Rüppell, House Gecko, Griff., ('Anim. King.'); 4, Ptyodactylus fimbriatus (Gecko fimbriatus of authors; Fimbriated Gecko, Griff., 'Anim. King.'); 5, Phyllodactylus porphyreus; 6, Gymnodactylus scaber (Stenodactylus scaber, of Rüppell; Cyrtodactylus of Gray)? 7, Gymnodactylus pulchellus (Gonyodactylus pulchellus of Wagler; Cyrtodactylus pulchellus, of Gray); 7, *b* represents a claw of the animal seen in profile.

Digestive System.—The numerous teeth of the Geckos are similar in form and length, placed on the same line, and fixed in a longitudinal furrow on the internal edge of the jaw by the external surface of their roots. The enamelled crowns are cutting, and their base is rounded. From their position in the jaw, Wagler has derived his designation *Pleurodonts*, the teeth being attached laterally while they are free internally, or in the furrow destined for their reception. In the greater number the crown increases from above downwards. These teeth are so closely set that they seem to touch each other, and altogether form a very trenchant dentilated blade, though not long enough for cutting up substances of any thickness, nor does the bite of the animal inflict a wound.

The œsophagus is very wide, and M. Duméril notices an extraordinary appearance therein, when it is remembered that the part is not exposed to the light. In many species, both living and dead, which he examined, he found the interior of this canal strongly coloured with different but uniform shades, sometimes of an orange-yellow, but principally of a deep black. There is no distinct limit between the œsophagus and the stomach; the crop (jabot) is continuous, and the whole forms a kind of longitudinal sac, which appears to be suddenly narrowed at the point corresponding to the pylorus, which is not to be detected except by this diminution of diameter and its position on the free and lower edge of the liver. The intestine is arranged in folds, and about three times the length of the œs and ventriculus taken together, it turns to the left, and is lost on the side of a true and large cœcum, furnished with an appendage, and terminating by a large tube which has its opening in the cloaca.

The triangular liver is placed in the mesial line, but its upper angle is so much elongated, that in some species it forms a conical point, at least twice as long as the base. This point lies in front of the stomach in the space left by the two lungs when they are filled with air. Below, the liver enlarges, and is divided into many lobes or indistinct strips, with the exception of that on the left, which is longest. The gall-bladder is situated under the mesial lobe. M. Duméril states that there does not appear to be a pancreas, but he observed in the *Common Gecko* and in the *Fimbriated Gecko* (*Ptyodactylus fimbriatus*) a very small spleen situated on the left side of the stomach.

Circulating System.—The shape of the heart varies. In the Common Gecko it is large and flat, but has nevertheless a tolerably regular conical form, the point of the cone being below, and the base, which is slightly notched, leaning on the root of the two lungs. In the *Fimbriated Gecko*, on the contrary, M. Duméril states the heart to be proportionally smaller, and apparently formed of three distinct but approximated portions, the two upper rounded and oval, resembling auricles, and the other and lower portions small and conical. He acknowledges that he has not followed out the vascular system, but presumes that it resembles in its distribution that of the other Saurians.

Respiratory System and Organ of Voice.—The glottis consists of a longitudinal slit with two large lips, which form a sort of tubercle behind the posterior notched portion of the tongue, the movements of which it follows, and can consequently be lifted up and applied to the concavity of the palate. The trachea is very large, and the rings, which are cartilaginous anteriorly but membranous on the side next to the œsophagus, cause it to be considerably flattened. The lungs form two sacs, as in the Salamanders, and are nearly equal in volume and length. Their internal cavity is simple, but there are polygonal cellules on their internal membranous linings, and in the lines forming these the arterial and venous vessels are ramified. The Geckotidæ are without any goître, and M. Duméril is unable to account for the production of the voice, but he inquires whether the cry which they emit, and which is supposed to be in some degree imitated by their names of 'Gecko,' 'Geitje,' &c., may not be assisted by the movements of the tongue, and its reception in the concavity of the palate; analogous, we suppose, to the production of the sound with which a coachman or groom stimulates his horses by applying the tongue to the upper part of the mouth and suddenly withdrawing it.

Urinary and Genital Organs.—There is no urinary bladder, nor do the rounded kidneys, whose ureters are not long and open directly into the cloaca, require particular notice. The organs of generation in the males (which are smaller, more agile, and more brightly coloured than the females) are double, and lodged on each side of the base of the tail, which has consequently a swollen appearance. The eggs, which are often deposited between stones, are quite round, with a rather solid, slightly rough, calcareous shell, of a uniform dirty white. M. Duméril has seen these eggs produce the young ones, which were well formed and very nimble.

Peculiar Secretions.—The author last named states that he has observed in many species, some peculiar organs, sometimes double, sometimes united in a single flattened elongated mass under the abdominal parietes in front of the pubis, in place of a urinary bladder. They appeared to be of a fatty nature, and were sustained in one part by the os pubis, and on the other possessed vascular or membranous single or double prolongations, rising in the thickness of the peritoneum as far as the liver. Though he knows not the office of these organs, he thinks it probable that they may be destined to afford nourishment to the animal in a state of hybernation. The pores of the thighs, &c. secrete a thick humor; and M. Duméril observes that these pores afford no generic character.

Habits, Food, &c.—The Geckotidæ are none of them large in size, and the greatest number feed on small animals, such as insects, their larvæ and pupæ. These they catch either by lying in ambush or by pursuing their feeble prey in the holes and dark crevices to which it retires. The structure of their feet enables them to run in every direction over the smoothest surfaces, and they can even remain suspended beneath the large leaves which a luxuriant tropical vegetation so frequently puts forth. The sharp and retractile nails with which the feet of the greater number are armed enable them to cling to and make rapid progress on trees with the smoothest bark, to penetrate the holes of rocks, and to climb walls. Of sombre or varying colours adapted generally to the locality where their lot is cast, they will often remain for hours in positions as extraordinary as the flies and insects for which they watch, the wonderful apparatus with which their feet is furnished enabling them to overcome the general law of gravity, and without which they would instantly fall to the earth. The hues of their skins thus render them less objects of suspicion to the little animals for which they lie in wait, and also serve to dodge even the acute eye of the bird of prey that seeks to destroy them. Their eyes, as we have seen, enable them to discern objects in the dark, and are at the same time capable of bearing the rays of a bright sun; for many insects are nocturnal or crepuscular, while the great mass of them are diurnal. The pursuit of their prey leads them near the habitations of man, whose dwelling always attracts certain kinds of insects, and they sometimes fall victims to their appearance, which frequently inspires terror, and often disgust. A Gecko, confident in his powers of flight, appears boldly to await his adversary, and his sudden disappearance at a nearer approach adds to the horror which ..... uncouth form inspires. The poor Geckos too have a bad name. They are supposed to poison whatsoever they touch, be it animate or inanimate, and their saliva is said to vex the skin of those on whom it falls with foul eruptions. Many of these cuticular irritations, when they have actually existed from the intervention of these animals, may have arisen from the extremely sharp claws of a Gecko running over a sleeping man, or small blisters may have been raised by the adherent apparatus at the bottom of its feet.

Geographical Distribution.—The form is found in all the four quarters of the globe, and is widely distributed in warm climates. In this distribution Europe, as far as observation has yet gone, claims by far the fewest number. Two species only have yet been found in this quarter of the globe, and even these are common to the northern coasts of Africa. The Prince of Musignano has noticed them in the 'Fauna Italica,' under the names of *Ascalabotes Mauritanicus* and *Hemidactylus triedrus*. The former is a Platydactylus of Duméril and others. In Asia the greatest number are found: thirteen species are recorded as Asiatic. Africa is said to possess twelve, and America eleven species, as far as researches have hitherto gone. In Australasia and Polynesia there are said to have been found twelve species. M. Duméril, in his Table, gives the following numbers:—In Europe, 2; in Asia, 13; common to both, none. In Africa, 12; in America, 12; common to both, none. In Australasia and Polynesia, 12. Of unknown origin, 4: = 55. In addition to the 13 Asiatic species, there is another which is also found in South Africa and in the neighbouring islands. Some of the African species are found also in Madagascar, the Mauritius, and the islands of Seychelles, Teneriffe and Madeira. It is not clear that Mr. Gray's genus *Gehyra*, which he characterizes from a Gecko ...d in an island of the Pacific Ocean, is included in this ...ation. Besides the species which Mr. Gray describes ...'Zool. Proc.' (1834), he alludes to the probability ...two other species, one in the British Museum, and another in the Museum d'Histoire Naturelle, at Paris.

Systematic Arrangement, &c.

There can be little doubt that the Ἀσκαλαβώτης of Aristotle and of the Greeks generally was a Gecko. Aristophanes and Theophrastus, as Gesner has shown, speak of those lizards which the Italians called *Tarentola*, whose bodies were short and thick, and which clambered about the walls

in the interior of their edifices for the purpose of catching spiders, on which they fed, under the names of *Ascalabotes* and *Galeotes*. That the *Stellio* of Pliny was no other than a Gecko, Schneider has shown.

Linnæus placed the *Geckos* under his great genus *Lacerta*, and recorded but three species (1766).

Laurenti (1768) seems to have been the first modern who established the *Geckos* as a genus. Gmelin (1789—13th edit. of *Syst. Nat.*) introduced a section in the genus *Lacerta*, consisting of five species, under the name of *Gekkones*, and the term Gecko was used as a generic appellation for these Saurians by Lacépède (1790), Schneider (1797), Cuvier (1798), and Brongniart (1801).

Daudin (1803) divided the genus *Gecko* into three sections, taking for the basis of his division the number and connexion of the toes, the form of the tail, and the disposition of the scales. These sections consisted of the *Geckos* properly so called, the *Geckottes*, and the *Geckos* with a flat tail. M. Duméril, who has written so much and so well on this subject, and to whose writings we are so much indebted, states that in 1806 he profited by the foregoing works, and established in the *Zoologie Analytique* and in his public lectures the genus *Uroplatus* (1806), and he says that Oppel, in his *Prodromus* (1811), established the family *Geckotidæ* after his (Duméril's) indications. M. Duméril, who established also the genus *Urotornus*, adopts in great measure the system of Cuvier, and separates the *Geckotidæ* into two great divisions, each embracing subdivisions. These divisions take the structure of the toes for their basis; the first consisting of those *Geckotidæ* which have dilated toes; the second of those whose toes are not dilated. The subdivisions depend upon the variation in the structure of the lower part of the toes. The genera are—*Ascalabotes*, *Platydactylus*, *Hemidactylus*, *Ptyodactylus*, *Thecadactylus*, *Stenodactylus*, and *Gymnodactylus* (1836).

Cuvier (1817—1829) placed these Saurians under his great genus *Gecko*, which he divided into the following subgenera:—*Platydactylus*, *Hemidactylus*, *Thecadactylus*, *Ptyodactylus*, *Sphæriodactylus*; at the same time arranging those Geckos which have retractile claws, but slender or rather not enlarged toes, in three groups, under the names of *Stenodactylus*, *Gymnodactylus*, and *Phyllura*, the latter embracing those with a horizontally-flattened, foliated tail.

Merrem (1820) places the Geckos in the 1st tribe (*Gradientia*) of the class *Pholidoti*. The sub-tribe *Ascalabotes*, according to him, embraces the *Iguanidæ*, as well as *Geckos*.

M. Latreille (1801-1825) seems to have adopted the views and descriptions of Lacépède in the first instance, and not to have gone much beyond a change of nomenclature in the last work published by him.

M. Fitzinger (1826) makes his *Ascalabotöids* consist of the genera *Sarrubus*, *Uroplatus*, *Ptyodactylus*, *Hemidactylus*, *Thecadactylus*, *Ptychozöon*, *Platydactylus*, *Ascalabotes*, *Stenodactylus*, and *Phyllurus*.

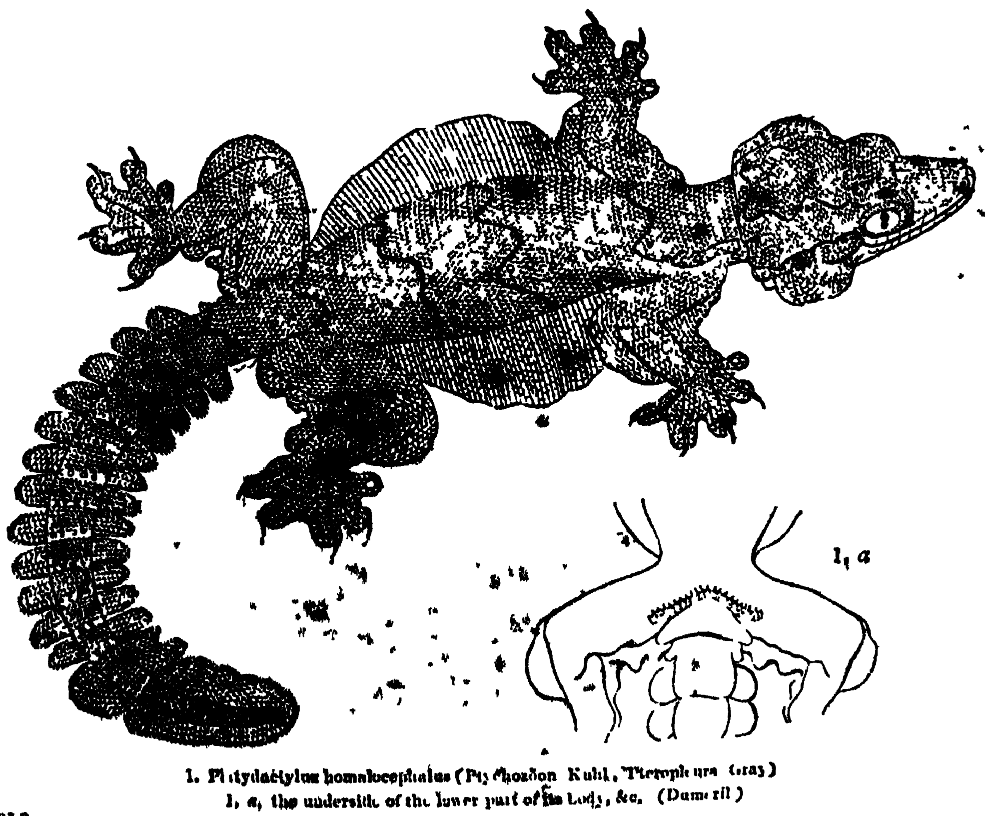
Mr. Gray (1827-1834) arranges the following genera under the family *Geckotidæ*:—*Hemidactylus*, *Platydactylus*, *Gecko*, *Pteropleura*, *Thecadactylus*, *Ptyodactylus*, *Phyllurus*, *Eublepharis*, *Cyrtodactylus*, *Phyllodactylus*, *Diplodactylus* (vol. ix., p. 11), and *Gehyra*.

Wagler (1830), under the family name of *Platyglossi*, makes the *Geckotidæ* consist of the following genera:—*Ptychozöon* (Kuhl), *Crossurus* (Wagler—*Uroplatus* of Duméril in part), *Rhacöessa* (Wagler—one of Duméril's *Uroplati*), *Thecadactylus* (Cuvier), *Platydactylus* (Cuvier), *Anoplopus* (Wagler), *Hemidactylus* (Cuvier), *Ptyodactylus* (Cuvier), *Sphæriodactylus* (Cuvier), *Ascalabotes* (Lichtenstein), *Eublepharis* (Gray), *Gonyodactylus* (Kuhl), and *Gymnodactylus* (Spix).

Dr. Cocteau (1835) arranges the Geckos in six divisions. 1, *Platydactylus*, containing five subdivisions, represented in part by *Anoplopus* of Wagler, *Phelsuma* (Cocteau), *Pachydactylus* (Wiegmann), *Ptychozöon* (Kuhl), and *Pteropleura* (Gray); with others resting principally upon the absence or presence of pores before the cloaca, and the development of the claws; 2, those Geckos which correspond to *Thecadactylus* of Cuvier; 3, *Hemidactylus*; 4, comprehending *Ptyodactylus* (*Uroplatus*, Duméril, *Rhacöessa*, Wagler, *Crossurus*, Wagler); 5, *Sphæriodactylus*, comprehending *Diplodactylus*, Gray, and *Phyllodactylus*, Gray; 6, *Stenodactylus*, (*Eublepharis*, *Gonyodactylus*, *Gymnodactylus*, *Cyrtodactylus*, *Pristurus*, *Phyllurus*).

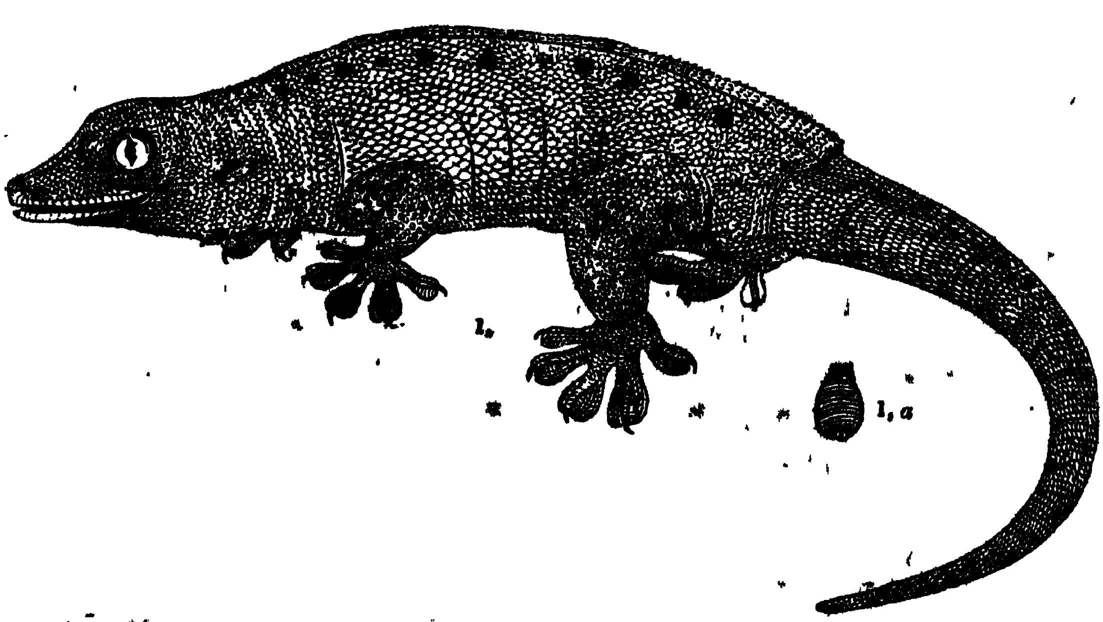
M. de Blainville ('Nouvelles Annales du Muséum,' April, 1836) places the family of *Geckos* at the head of the family of *Saurophians*. The species forming the genus *Platydactylus* of Cuvier he designates as *Geckos*; those ranging under *Hemidactylus* as *Demi-Geckos*; the *Ptyodactyli* as *Tiers-Geckos*; the *Stenodactyli* as *Quart-Geckos*; and the *Gymnodactyli* as *Sub-Geckos*.

The following cuts will convey an idea of the form of some of the Geckotidæ:—



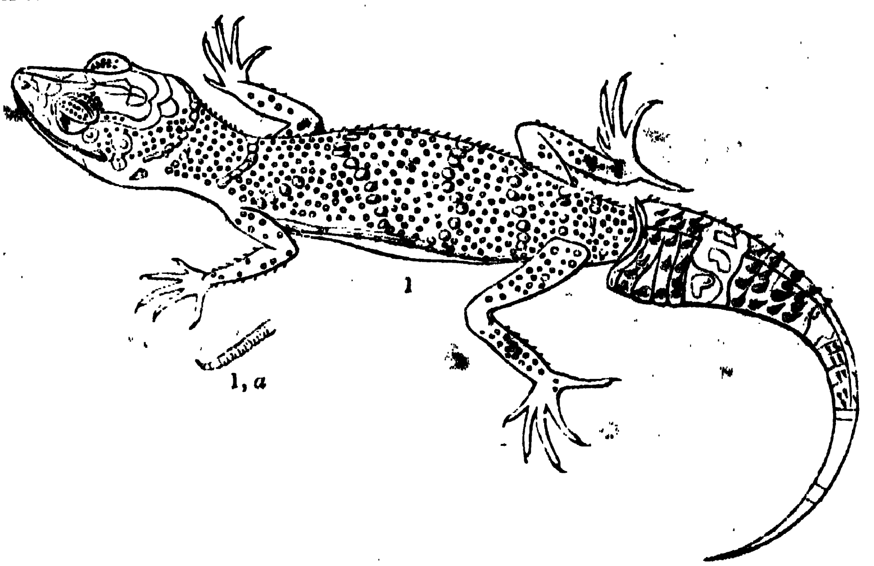
1. Platydactylus homalocephalus (Ptychozöon Kuhl, Pteropleura Gray)
1, a, the underside of the lower part of its body, &c. (Duméril)

Locality, Java.
P. C., No. 671.



1. Platydactylus Seychellensis. (Duméril.)
1, a, the underside of one of its toes.

Locality, the Seychelles Islands.



1. Gymnodactylus Milliusii (Cyrtodactylus Milliusii, Gray).
1, a, the underside of one of its toes. (Duméril.)

Locality, New Holland.

The student who wishes to follow out the natural history of this family of Saurians should consult the works of Aldrovandi, Aristotle, Bonaparte (Prince of Musignano), Brongniart, Creveldt, Cuvier, Duméril, Edwards, Eichvald, Feuillée, Flacourt, Geoffroy, Gesner, Gmelin, Gray, Hermann, Houttuyn, Knorr, Kuhl, Lacépède, Latreille, Lesson, Lichtenstein, Linnæus, the Prince of Neuwied, Oppel, Osbeck, Pallas, Perrault, Pisa, Pliny, Rafinesque, Risso, Rüppel, Ruysch, Schneider, Schinz, Seba, Sparmann, Spix, Tilesius, Wagler, White, Wiegmann, and Wormius.

GEDDES, ALEXANDER, LL.D., was born at Arradowl, in the parish of Ruthven and county of Banff, in Scotland, in A.D. 1737. His parents, who were in humble circumstances, were enabled, by the kindness of the laird of the village, to give their son a respectable education. After spending seven years at Scalan, a Roman Catholic seminary in the Highlands, he was removed at the age of twenty-one to the Scotch college in Paris, where he diligently studied theology, and made himself master of most of the modern European languages. On his return to Scotland he resided for some time in the house of the Earl of Traquaire; and, after paying another visit to Paris, he accepted, in 1769, the charge of a Catholic congregation at Auchinhalrig in the county of Banff, where he remained for ten years, beloved by his people, and attentive to the duties of his station. He had resolved—in the early years of his life to make a new translation of the Bible into the English language, for the use of the Roman Catholics; but pecuniary difficulties prevented him during his residence at Auchinhalrig from obtaining the necessary books. On his removal to London, in 1779, he was introduced to Lord Petre, who warmly approved of his purpose, and engaged to allow him 200*l.* a year for his life, and to procure for him all the works that he considered requisite. Thus encouraged he published, in 1780, a pamphlet under the title of an 'Idea of a new version of the Holy Bible, for the use of the English Catholics,' in which he proposed to make the Vulgate the basis of his new translation. This plan being afterwards abandoned, he resolved to make an entirely new translation from the Hebrew and Greek; for if he had adopted the former method, he stated 'that he must have been perpetually confronting the Vulgate with the originals, and very often correcting it by them; or presented his readers with a very unfair and imperfect representation of the sacred text.' In accomplishing this work, his first object was directed to obtaining an accurate text, and no labour was spared by this indefatigable scholar to render the translation as complete as possible. He consulted the most eminent biblical scholars of the day, among whom were Dr. Kennicott, and Dr. Lowth, the bishop of London, who assisted him with their advice. The prospectus, which contained an account of his plan, was published in 1786; this was soon followed by a letter to the

bishop of London, containing 'Queries, doubts, and difficulties, relative to a vernacular version of the Holy Scriptures,' by a specimen of the work, and by a 'General Answer to the queries, counsels, and criticisms' which his prospectus and specimens had called forth. It was not however till 1792 that the first volume of the translation was published under the title of 'The Holy Bible, or the Books accounted sacred by the Jews and Christians, otherwise called the Books of the Old and New Covenants, faithfully translated from corrected texts of the originals, with various readings, explanatory notes, and critical remarks;' the second, which contained the translation to the end of the historical books, appeared in 1793; and the third, which contained his critical remarks upon the Pentateuch, in 1800. The remainder of the work was never finished; he was employed at the time of his death on a translation of the Psalms, which he had finished as far as the 118th Psalm, and which was published in 1807. He died at London on the 26th of February, 1802, in the 65th year of his age.

In his translation and commentary Dr. Geddes maintained opinions very similar to those held by that class of divines in Germany denominated *Rationalist*, and of whom Eichhorn and Paulus were the most celebrated in his day. He considered the writers of the Scriptures to have had the same degree of inspiration which has been granted to good men in all ages, and which, according to the common meaning attached to the word inspiration, amounts to none at all. He disbelieved the divine mission of Moses, and asserted that 'Moses only did what all other antient legislators had done, required a greater or less degree of implicit obedience to their respective laws, and for that purpose feigned an intercourse with the Deity to make that obedience more palatable to the credulous multitude.' He rejected the various miracles ascribed to him, or laboured to reduce them to the standard of natural phenomena. He explains the account of the creation in the book of Genesis 'as a most beautiful mythos or philosophical fiction, contrived with great wisdom, and dressed up in the garb of real history.' These and similar opinions exposed the author to severe censure; and charges of infidelity and of a desire to undermine the authority of the Scriptures were widely circulated against him. His own church was the first to condemn him; a pastoral letter, signed by three out of four of the apostolical vicars of England, forbad the faithful from reading his translation; and Dr. Geddes himself was soon afterwards deposed by the apostolical vicar of the London district from the exercise of his duties as a priest. We cannot be surprised at this, for though he professed himself a member of the Catholic Church, he disclaimed all papal authority, and was strongly opposed to many of the tenets of that church. His heterodox opinions on these subjects had occasioned a similar suspension from his office when he officiated as priest at Auchinhalrig. To vindicate his character Dr. Geddes published an 'Address to the public on the publication of the first volume of his new translation of the Bible,' in which he repelled the charge of infidelity, and asserted, 'I willingly confess myself a sincere though unworthy disciple of Christ; Christian is my name, and Catholic my surname—rather than renounce these titles I would shed my blood.' We have no reason for doubting the truth of this declaration; his whole life showed that he was a diligent inquirer after truth. Though we may consider the opinions of Dr. Geddes as detrimental to the authority of the Scriptures, we have no reason on that account for charging him with infidelity, since he believed that his interpretation of the Scriptures tended to place Christianity on a firmer basis, and that 'those were the enemies of religion who seek to support her on rotten props, which moulder away at the first touch of reason, and leave the fabric in the dust.' His translation is well described by Dr. Mason Good (*Life of Geddes*, p. 358) to be, 'for the most part, plain and perspicuous, conveying the sense of the original in its native simplicity. But his language is occasionally unequal, and strongly partakes of the alternations of his own physical constitution; in consequence of which, in the midst of a passage most exquisitely rendered in the main, we are at times surprised with scholastic and extraneous expressions, or disgusted with intolerable vulgarisms.' It cannot be denied that his work was a valuable help to the science of biblical criticism in this country, and it must have been a source of consolation to him, in the midst of the virulence with which he was assailed in England, to know that such men as Paulus and Eichhorn appreciated his labours; the latter of whom observed that Dr. Geddes was the only individual by whose opinion he would consent to be judged.

In addition to his translation, Dr. Geddes published many other works, most of which had only a temporary interest, as they were written on the politics of the day, or on some theological or literary dispute which has long since been settled. A complete catalogue of them is given in the beginning of Dr. Mason Good's 'Memoirs of the Life and Writings of the Rev. Alexander Geddes, LL.D.,' published in 1803. (See Graves *on the Pentateuch*, and the 4th, 14th, 19th, and 20th volumes of the *British Critic*, old series, for a review of his theological opinions.)

GEDIKE, FRIEDRICH, was born at Boberow, near Lenzen in Brandenburg in the year 1754. The death of his father, when he was but nine years old, plunged him in great distress, and he was taken to the Orphan Asylum at Züllichau. Dr. Steinbart, who was director of the public institutions for instruction in this place, educated him seven years at the Asylum. In 1766 Steinbart founded a school of his own, where Gedike became a pupil, and here talents which had hitherto lain dormant began to manifest themselves. He went to the university at Frankfort in 1771, and studied under Töllner. On the death of Töllner, Steinbart, who succeeded him, once more became his instructor. In 1775 Spalding appointed Gedike private teacher to his two sons, and in 1776 he was made subrector of the Friedrichwerder Gymnasium at Berlin, of which in a few years he became director. He now showed himself to be one of the most eminent teachers in Germany. Indefatigable in devising new methods of instruction, and constantly aiming at improvements, he animated both pupils and tutors, and raised the almost sinking establishment to a high eminence. He became in 1795 director of the Berlin Gymnasium, having previously received the degree of doctor of theology. He died in 1803.

The works of Gedike are chiefly school-books and works on education, but he also published an edition of the 'Philoctetes' of Sophocles, and of select dialogues from Plato, as well as some translations of Pindar, which are mentioned with respect.

GEERTRUYDENBERG. [BRABANT.]

GEESE. [GOOSE.]

GEHLENITE, a mineral which occurs in imbedded and massive aggregations of rectangular or slightly rhombic crystals. Primary form uncertain. Cleavage parallel to the planes of a rectangular or rhombic prism. Surface usually rough and dark. Fracture uneven, passing into splintery. Hardness, 5·5 to 6. Colour in general grey, frequently with a yellowish or greenish tint. Lustre slightly vitreous, resinous. Translucent slightly or opaque. Specific gravity, 2·832 to 3·029.

Before the blowpipe gehlenite suffers no change when alone. With borax it melts with difficulty into a glass coloured by oxide of iron. When heated in hydrochloric acid it gelatinizes.

This mineral occurs only in the valley of Fassa in the Tyrol. By analysis it yielded, according to

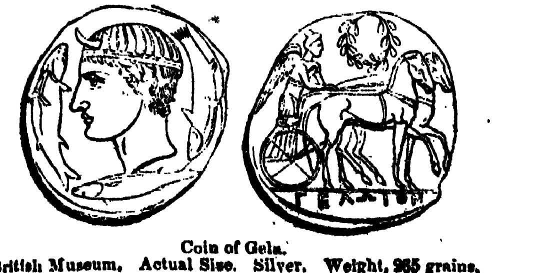
GEHYRA. [GECKO, vol. xi., pp. 104, 105.]

GELA, a Grecian colony on the south-western coast of Sicily, was founded by a joint colony from Crete and from Lindus, a city in Rhodes, forty-five years after the foundation of Syracuse. (Herod., vii. 153; Thuc., vi. 4.) It was



Coin of Gela.
British Museum. Actual Size. Silver. Weight, 265 grains.

one of the most powerful of the Grecian colonies in Sicily, and continued so to the time of Gelon [Gelon], who removed the greater part of its inhabitants to Syracuse: after which it rapidly sunk in importance, and never again obtained its former power. The modern town of *Terra Nova* is supposed to have been built upon its site. The Minotaur on the coin of Gela, below, is symbolical of the origin of the city.

Coin of Gela.
British Museum. Actual size. Silver. Weight, 269½ grains.

GELA'SIMUS, a genus of Brachyurous Crustaceans. [Ocypodians.]

GELA'SIUS I. succeeded Felix II. as bishop of Rome, A.D. 492, and carried on the controversy with the Greek church which had begun under his predecessor, but without bringing it to any conclusion. He died in 496, and was succeeded by Anastasius II. Gelasius wrote several theological works, such as 'De Duabus Naturis in Christo,' in which he expresses sentiments which are considered as opposed to transubstantiation. It is found in the Lyon *Bibliotheca Maxima Patrum*.

GELA'SIUS II., a Benedictine monk, succeeded Paschal II., A.D. 1118. The popes were then at open war with the emperors of Germany; and the partizans of the latter at Rome, headed by the powerful family of Frangipani, opposed the election of Gelasius, and afterwards seized him and personally ill-treated him, until he was rescued from their hands by the præfect of Rome. Soon after, the Emperor Henry V. came himself with troops, and the pope having run away to Gaëta, an anti-pope was elected by the Imperial party, who styled himself Gregory VIII. Gelasius, after many wanderings, repaired to France, where he held a council at Rheims. He died at the convent of Cluny, in January, 1119, after a short but stormy pontificate, and was succeeded by Calixtus II.

GELATIN. [Food, vol. x., p. 343.]

GELDER ROSE, or rather, GUELDRES ROSE, a double variety of the Viburnum Opulus, a marsh shrub, common in this country and all the north of Europe. The name of this variety is supposed to indicate its origin in the Low Countries: it is also called the snowball-tree, in allusion to its large white balls of flowers.

GELE'E, CLAUDE. [Claude Lorraine.]

GELLERT, CHRISTIAN FURCHTEGOTT, born near Chemnitz, in Saxony, acquired a great reputation as a writer of fables and as a moralist. The simplicity of his manners, his candour, and goodness of heart, contributed to render him popular with all classes. Frederic II. and Prince Henry were very partial to him, notwithstanding his habitual shyness. His 'Fabeln und Erzählungen' had a prodigious success in Germany. He also wrote 'Sacred Odes and Songs,' which are much esteemed. His 'Letters' have also been published. The collection of his works, 'Sämmtliche Werke,' forms part of the 'Karlsruher Deutscher Classiker,' 1823-6. His fables and letters were translated into French, 5 vols. 8vo., with a biographical notice of the author. Gellert died at Leipzig, where he was professor of philosophy, in December, 1769, and a monument was raised to him in the church of St. John, with a cast of his head in bronze. The bookseller Wendler, who published his works, also raised a monument to the memory of Gellert in his garden.

GE'LLIUS, AULUS (or, according to some writers, Agellius), the author of the 'Noctes Atticæ,' was born at Rome in the early part of the second century, and died at the beginning of the reign of the Emperor Marcus Aurelius. We have few particulars of his life; we know that he studied rhetoric under Cornelius Fronto at Rome, and under Phavorinus at Athens, and that he was appointed at an early age to a judicial office. (*Noct. Att.* xiv. 2.) The 'Noctes Atticæ' was written, as he informs us in the preface to the work, during the winter evenings in Attica, to amuse his children in their hours of relaxation. It appears from his own account, that he had been accustomed to keep a common-place book, in which he entered whatever he heard in conversation or met with in his private reading that appeared worthy of memory. In composing his 'Noctes Atticæ,' he seems merely to have copied the contents of his common-place book with a little alteration in the language, but without any attempt at classification or arrangement. This work contains anecdotes and arguments, scraps of history and pieces of poetry, and dissertations on various points in philosophy, geometry, and grammar. Amidst much that is trifling and puerile, we obtain information on many subjects relating to antiquity, of which we must otherwise have been ignorant. It is divided into twenty books, which are still extant, with the exception of the eighth and the beginning of the seventh. He mentions, in the conclusion of his preface, his intention of continuing the work, which he probably never carried into effect. The 'Noctes Atticæ' was printed for the first time at Rome, 1469, and has been frequently reprinted; the most valuable editions are the Bipont., 2 vols. 8vo. 1784, the one published by Gronovius, 4to. 1706, and a recent one by Lion, 2 vols. 8vo., Göttingen, 1824. The work has been translated into English by Beloe, 3 vols. 8vo., London, 1795; and into French, by Douzé de Verteuil, 3 vols. 12mo., Paris, 1776—1777.

GELON, a native of Gela, rose from the station of a private citizen to be supreme ruler of Gela and Syracuse. He was descended from an ancient family, which originally came from Telus, an island off the coast of Caria, and settled at Gela when it was first colonized by the Rhodians; at which place his ancestors held the office of hereditary minister of the infernal gods (χθόνιοι θεοί (Herodotus, vii. 153). During the time that Hippocrates reigned at Gela (B.C. 498—491), Gelon was appointed commander of the cavalry, and greatly distinguished himself in the various wars that Hippocrates carried on against the Grecian cities in Sicily. On the death of Hippocrates, who fell in a battle against the Siceli, Gelon seized the supreme power (B.C. 491). Soon afterwards a more splendid prize fell in his way. The nobles and landholders (γαμόροι) of Syracuse, who had been expelled from the city by an insurrection of their slaves supported by the rest of the people, applied to Gelon for assistance. This crafty prince gladly availing himself of the opportunity of extending his dominions, marched to Syracuse, into which he was admitted by the popular party (B.C. 485), who had not the means of resisting so formidable an opponent. (Herodotus, vii. 154, 155.) Having thus become master of Syracuse, he appointed his brother Hieron governor of Gela, and exerted all his endeavours to promote the prosperity of his new acquisition. In order to increase the population of Syracuse, he destroyed Camarina, and removed all its inhabitants, together with a great number of the citizens of Gela, to his favourite city. As he was indebted for his power in Syracuse to the aristocratical party, he took care to strengthen it against the people. Thus when he conquered the Megarians and Eubœans of Sicily, he transplanted to Syracuse all those who were possessed of wealth, but sold the remainder as slaves. (Herod. vii. 156.) By his various conquests and his great abilities he had become a very powerful monarch; and therefore, when the Greeks expected the invasion of Xerxes, ambassadors were sent to Syracuse to secure if possible his assistance in the war. Gelon promised to send to their aid 200 triremes, 20,000 heavy-armed troops, 2000 cavalry, and 6000 light-armed troops, provided the supreme command were given to him. This offer being indignantly rejected by the Lacedæmonian and Athenian ambassadors, Gelon sent, according to Herodotus, an individual named Cadmus to Delphi with great treasures, with orders to present them to Xerxes if he proved victorious in the coming war. (Herod. vii. 157—164.) This statement however was denied by the Syracusans, who said that Gelon would have assisted the Greeks, if he had not been prevented by an invasion of the Carthaginians with a force amounting to 300,000 men under the command of Hamilcar. This great army was entirely defeated near Himera by Gelon, and Theron, monarch of Agrigentum, on the same day on which the battle of Salamis was fought. (Herod. vii. 165—167.) An account of this expedition is also given by Diodorus (b. xi. p. 254, Steph.), who states that the battle between Gelon and the Carthaginians was fought on the same day as that of Thermopylæ.

Gelon appears to have used with moderation the power which he had acquired by violence, and to have endeared himself to the Syracusans by the equity of his government and the encouragement he gave to commerce and the fine arts,

There are still existing many coins of Gelon and his successor Hieron, of beautiful workmanship, of which a description is given in Mionnet, vol. i. p. 328. It is supposed by some that these coins were not struck in the time of Gelon, but by order of Hieron II. (B.C. 275—216), a supposition somewhat inconsistent with the number of coins still remaining. We are informed by Plutarch, that posterity remembered with gratitude the virtues and abilities of Gelon, and that the Syracusans would not allow his statue to be destroyed, together with those of the other tyrants, when Timoleon was master of the city. ('Life of Timoleon,' p. 247.) He died B.C. 478, and was succeeded by his brother Hieron. (Aristotle, *Polit.* b. v., c. 12, p. 678, Elzevir.)

This constellation derives its name from two remarkable stars, of the first and second magnitude, to which the names of Castor (or α Geminorum) and Pollux (or β Geminorum) are given. The latter star is marked by Flamsteed as of the first magnitude, by the greater part of astronomers as of the second, and by Piazzi as of the third! These two stars, whose proximity will cause them to be easily recognised when once known, may be found by drawing a line through the belt of Orion and the two bright stars the line of which cuts through the belt. This line, lengthened upwards, will pass very near to the two stars of Gemini. They are also about halfway between Regulus and Aldebaran: and if the Great Bear and Orion be seen together, then Capella on the one side, and Castor and Pollux on the other, will be conspicuous boundaries of the intermediate space.

GEMINIA'NI, FRANCESCO, a very distinguished composer, and also a famous violinist, was born at Lucca, about the year 1680. The foundation of his profesional knowledge was laid by Alessandro Scarlatti, but he completed his studies under Corelli. England was then, as now, the place of attraction for foreign musical talent, and Geminiani arrived in London in 1714, where his performance speedily gave him celebrity. He soon became acquainted with Baron Kilmansegge, chamberlain to George I. as Elector of Hanover, through whose means he was introduced to the king, and had the honour to perform before that sovereign some of his recently published Sonatas, for '*Violino, Violone, e Cembalo*,' in which Handel accompanied him on the harpsichord. Successful as he was professionally, his finances were continually in a disordered state, for some demon whispered 'Have a taste,' and following such seductive advice, he indulged in the passion for collecting pictures, which he often sold again at a loss, and thus not only expended all that his talent and labour acquired, but too frequently was tempted to neglect his business. Embarrassed circumstances were the unavoidable result; he therefore applied for the appointment of Composer of State Music in Ireland, and through the interest of the Earl of Essex was nominated to that good situation; but belonging to the Catholic communion, and, though no bigot, refusing to take oaths irreconcilable to his conscience, the office was given to his pupil, Matthew Dubourg. He now set down industriously to compose, and published numerous works. Six of Corelli's Solos and as many of that great musician's Sonatas he converted into Concertos for a band, and in so efficient a manner, that some of them are yet annually listened to with delight at the Ancient Concerts. These were followed by his own Six Orchestral Concertos, *Opera Terza*, and Twelve Sonatas for Violin and Base, all of which abound in beautiful melody, and evince his skill in harmony. His deep knowledge of the latter was further exhibited soon after, in his *Guida Armonica*, which the old musicians treated as one of those attempts at innovation that ought to be resisted, and omitted no means in their power to prevent the sale of a work which they had not wit enough to understand. A French critic however, the Père Castel, wrote a vindication of it in the *Journal des Savans*, a publication of vast influence at that time, and Geminiani finally triumphed over his obstinate and jealous opponents. But as the emoluments arising from his many publications were by no means commensurate to the thought and time necessarily bestowed on them, or to his expensive habits, his necessities still pursued him, and he had recourse to a kind of benefit-concert at Drury Lane theatre, by which he made a considerable sum, and was thus enabled to gratify his love of travelling. He went to Paris, and there printed two sets of Concertos. On his return to England he continued composing and publishing. In 1761 he paid a visit to his friend Dubourg, in Dublin; but soon after his arrival in that city he lost, through the treachery of a servant, a manuscript treatise on music, on which he had bestowed much time and labour, and on the success of which his hopes of future independence were founded. This he never recovered; and the circumstance so preyed on his mind, that we are told it shortened his life, though probably not by any long period, for he reached his eighty-third year, and breathed his last in the Irish capital in 1762.

GEMMASTRÆA. [MADREPHYLLIÆA.]

GEMMULI'NA. [FORAMINIFERA, vol. x., p. 346.]

GEMS. [CAMEO; INTAGLIO.]

GENDARMERIE (from *Gens d'Armes*, men-at-arms) was a chosen corps of cavalry under the old monarchy of France: it is mentioned with praise in the wars of Louis XIII. and Louis XIV. Under the present system the gendarmerie is a body of soldiers entrusted with the police

all over France; it furnishes patrols, arrests criminals, examines the passports of travellers, and contributes to the maintenance of good order. Gendarmes are generally stationed at the barriers or gates of the towns, at the principal inns on the roads, at markets and fairs, and along the lines of the frontiers. They are divided into foot and horse: *gendarmes à pied, gendarmes à cheval*. They form a distinct corps in the army, under their own superior officers, who are under the orders of the ministers of the interior and of police; but in case of war, they may be called into active service like the other corps of the army. The gendarmerie is mostly recruited from old and deserving soldiers of other regiments, who consider it as a promotion, as they have better pay and enjoy greater liberty. This explains why the gendarmes, generally speaking, are remarkably well behaved and trusty men, who, while strictly executing their duties, behave with considerable civility towards unoffending people, such as travellers, and especially foreigners. The same description of troops exists in the Italian states, where they are called Carabineers.

GENDER is a grammatical principle entering into the structure of nearly every language, according to which nouns are distributed into classes. There are, strictly speaking, but two genders, *masculine* and *feminine*; those which belong to neither of those classes were said to be *neutrius generis*, of neither gender: this third class are called somewhat incorrectly *neuters*, and hence by a second irregularity it is the ordinary practice of grammarians to speak of three genders.

That sexual distinction was the fountain from whence the doctrine of grammatical gender was derived cannot be reasonably disputed. As a consequence of this the principle must have been confined originally to living beings, and among these it must have been still further limited to those animals where the distinction of the sex was readily perceived, as in the mane of the lion, the plumage of the peacock, or the magnitude of the bull. In the smaller animals it would be often difficult to ascertain the sex, and useless to denote it. But utility and truth are not the sole governing principles of language; they are often sacrificed to the love of imagery and personification. Thus the beautiful and pleasing absurdity which characterises the language of fable recommends itself to the infant mind whether of the savage or the child. The rose, the lily, the sun, the moon, are all endowed with the faculty of speech, and it then becomes almost necessary to add the distinction of sex. Here the choice must depend upon the association of ideas. Action, freedom, strength, magnitude, and violence, are the marked attributes of the male; sufferance, subjection, timidity, together with pregnancy, of the female. In the application of these notions, the realities of nature are often neglected. The domestic animals, having lost all the violence of the natural state, convey to the mind the idea of something feminine. Thus among the Romans even the dog was in ordinary language considered to be of that gender; while the English, contrasting that noble and powerful animal with the clean and delicate but irritable cat, have allotted the masculine gender to the dog, to the other the feminine. The feathered creation again, by their small size, their weakness, and the delicacy of their plumage, are naturally associated with the tender sex, with the exception commonly of the eagle, kite, hawk, &c.

In the meanwhile the neuter is employed to denote that the notion of gender is not entertained; it is therefore, as Grimm has well observed, the proper grammatical form for the young of animals where the sexual distinctions are imperfectly developed. Thus in the greater part of the Teutonic languages, the terms for *foal, calf, lamb, child*, &c., are of the neuter gender; and in the Greek there occur many similar forms, as *τεκνον, βρεφος*, &c. Hence by an easy connexion the diminutives generally in the Greek and Teutonic languages are of the same gender. In the further extension of the idea of gender, first to material objects without life, and then to abstract terms and mental notions, the directing associations are weaker, and the mind is in a state of oscillation. It may be observed however that abstract nouns, or to speak more correctly, general terms, are usually included among the feminines, perhaps from a notion of pregnancy, the one term including a large aggregate of concrete ideas. There are indeed exceptions to this principle; for instance, in the large family of Latin words which have the suffix *or* (*honor, pudor*, &c.), but this variety is probably to be explained by the similarity of the termination to the masculine suffix *tor*. The French language has corrected this anomaly in *la pudeur*, &c.

The mode of denoting gender is also deserving of consideration. One of the most direct methods would appear to be to assign names absolutely different to the male and female, that is, in those cases where the terms are used in their natural, not their metaphorical sense. Thus we have in our own language *boy* and *girl, horse* and *mare, bull* and *cow*, &c. One of the defects of such a principle would be the want of a general rule by which to denote the gender in any new instance, and the consequent multiplication of terms. But independently of the advantages and disadvantages of this notation, there are good reasons for believing that in fact the distinction of sex was not originally denoted by an absolute difference of term.

The word *man*, for instance, in the oldest Teutonic language had the general meaning of a human being, like the Greek *ανθρωπος*, or Latin *homo*, and only gained the exclusive notion of a male when its derivative *mannisco* or *mensche* was formed to express the general idea. The German term *frau* again is now confined to the female, but there is found in nearly all the older dialects of the German a masculine so nearly identical (*frauha*, Gothic; *frô*, old high German; *froho*, old Saxon; *frea*, Anglo-Saxon) that the notion of the female can scarcely have been inherent in the word. Similar results would be given by an examination of the English word *maid*, the Latin *puer*, &c. In the animal kingdom the same confusion prevails. The Latin *ovis* is commonly feminine; and in fact our English term *ewe* may be indisputably proved to be the same word; still, in the earlier form of the Latin language, the word was also applied in the sense of *aries*. It occurs, for instance, in the name of the sacrifice *Suovetaurilia*, where the word *taurus* leads us to expect the idea of a *ram* in *ovis*, and of a boar in *sus*; and in fact antient reliefs prove that the animals sacrificed at this festival were uncastrated males. The word *sus*, corresponding in ordinary signification, as also in form, to the English *sow*, is a parallel case. Indeed the Greek language exhibits this very word as not confined to either sex. A long enumeration of similar instances, with the necessary proofs, would be out of place here. It will be sufficient to notice that the English terms *mare* and *hen* appear in other branches of the Teutonic language as representatives of the male. Lastly, those who attribute to those monosyllabic forms a distinct notion of gender will find it difficult to avoid the inference that if *gallus*, for example, originally meant a *cock*, and not, as is here maintained, a *fowl* generally, *gallina* included the notion of both sexes, a *female cock*. A more simple mode of denoting gender is by the addition of a special suffix. Thus the Latin termination *on*, like the Italian *one*, appears to have carried with it the idea of magnitude, as in the familiar cognomina *Nuson, Capiton*, &c. It was therefore well adapted to denote the male gender, which is commonly accompanied by superior magnitude. Thus *leon*, a lion, is in reality formed of two words, *le* or *li*, the simple name of the animal, and *on*, great. The form *li* (nom. λις) occurs in the Greek language as well as λεων; and moreover, if the name of the animal was thus monosyllabic, it is seen at once how natural it was to adopt it, as was in fact the case, for the hieroglyphical symbol, or at any rate for the Hebrew character of the letter *l*. The addition of the feminine suffix *ina* or *aina* to the same root *le* gave the female *leaena*; and indeed the same suffix appears in *gallina, regina*, the Greek *βασιλιννα*, the German *königinn*, &c. Of the male suffix other examples may be seen in *centurion, capon, falcon, pavon*, &c.; the last of which may be compared with the Greek *ταως*, and the English *pea-cock*. The most frequent suffix in the Greek language to denote the feminine is the syllable *sa*, as in *Phoinissa, Kilissa*, and the participles *tuptont-sa*, the parent of *tuptousa, tuphthent-sa*, afterwards *tuphtheisa*. The same suffix is found in the Gothic, as *gait-sa, capra*; and in German, as *farre*, a bull, *färse*, a cow. Our own language too is familiar with what is probably the same suffix in *seamstr-ess, laundress* (from *lavender-ess*). In the Greek language this suffix appears at times to have lost its sibilant, as was so common in that language. Hence the forms *βασιλε-ια, οἰκ-ια, τετυφυ-ια*, for *τετυφοτ-ια*.

Thus, at last, the vowel *a* appeared to be the characteristic of the feminine gender; and it would appear to be the result of error rather than of principle, that in the Latin language the first declension got connected with that gender. The forms *scriba, incola*, &c., with the numerous

proper names, *Cinna*, *Sulla*, &c., prove that the notion of the female was not inherent in this declension; and probably the fact was that there co-existed in Italy two dialects, one preferring *a*, the other *o* (precisely as in our own island, there are the two forms *two* and *twa*, *who* and *wha*, *one* and *ane*); and secondly, that by a false refinement in language, an arbitrary distinction of gender was set up between them. The same argument of course applies to the Greek form *ἀγαθο-ς* and *ἀγαθα* or *ἀγαθη*, in which it must be carefully recollected that the sibilant at the end of *ἀγαθος* has nothing to do with the question, as it is simply the representative of the nominative case. It should also be recollected that the older Greek language abounds in the common adjectives, such as ὁ and ἡ *ἀθανατος*. Moreover the advocates of an original distinction of gender in the two first declensions have to explain the anomalies of such forms as ἡ *ὁδος*, &c., and the Latin *manus*, *fagus*, &c. Again, that the Latin forms *bono* and *bona* were originally but dialectic varieties appears to be established by the consideration that nearly all derivatives from the second declension take an *a*, as *albare*, *aurare*, &c., a strange consequence of which is, that the Latin language is almost wholly deprived of a conjugation of verbs in *o* corresponding to the Greek *δουλο,ω*. It is a strange fact too, that in Gothic the forms in *a* are masculine, those in *o* feminine.

On this subject it may be permitted to quote a passage containing a similar argument from Coleridge's 'Table Talk,' i. 119:—'Originally, I apprehend, in the 'Platt-Deutsch' of the north of Germany there were only two definite articles, *die* for the masculine and feminine, and *das* for the neuter. Then it was *die sonne* in a masculine sense, as we say *the sun*. Luther, in constructing the *Hoch-Deutsch* (for really his miraculous and providential translation of the Bible was the fundamental act of construction of the literary German), took for his masculine article the *der* of the Ober-Deutsch, and thus constituted the three articles of the present high German, *der*, *die*, *das*.'

Lastly, every language has the power of denoting gender by the addition of a distinct word, as in *jack-snipe*, *cock-sparrow*, *tom-cat*. This use of the names of men is seen in other languages besides our own. Thus the Anglo-Saxon employs *carl* for this purpose; and the suffix *erick*, or *erich*, or *erock*, would also appear to have been originally a proper name, though attached to the names of male birds, as *taub-erich*, *gänserich*, &c., in German. Violent corruptions of this form exist in our own tongue in *lark*, abbreviated from *laverock*, a term still used in Scotland; and *drake* from *andrake*, itself a corruption from *anat-erock*.

Many suffixes which denote simply an agent are erroneously supposed to include the idea of gender. Thus the word *spinster* is in modern use solely significant of a female; but this arises from the accident that in the olden time the duty of spinning was confined to the female. The same termination *ster* is seen in the old words *brewster*, *webster*, *bagster*, now more commonly expressed, at least in England, by *brewer*, *weaver*, *baker*; and these certainly belong not exclusively to the female.

Nothing has been said of suffixes to denote the neuter gender; simply because there exist, strictly speaking, no such suffixes. There are indeed appearances of such additions; first, in the Greek neuters *ἀγαθον* and the Latin *bonum*; secondly, in the neuter pronouns of the Latin language terminating with a *d*, which correspond to an *s* in German and a *t* in English; as *quod*, *was*, *what*; *id*, *es*, *it*, &c. Of the first class it is enough perhaps to throw out a suspicion that the letter *n* is merely an outgrowth from the preceding vowel *o*. [See O.] As to the second, if the letter had been really representative of the neuter gender, it ought to have run through the genitives and datives as well as the nominatives and accusatives; so that the Latin language, for instance, should have given us the forms *idius idi*, not *eius ei* for the neuter. The English form *its* is no answer to this objection, as it is well known that this little word has been but a short time naturalized. In the age of Shakspeare the only form for the neuter genitive was *his*, as appears in the original editions. But in fact it would be ridiculous to have a suffix to denote a negation.

GENDRE, LE. [LEGENDRE.]

GENEALOGY. [PEDIGREE.]

GE'NERA, in ancient Greek music, were of three kinds, —the Diatonic, Chromatic, and Enharmonic. [DIATONIC; CHROMATIC; ENHARMONIC.] These were subdivided into many species, which are enumerated by Gaudentius and Aristoxenus. 'Indeed,' says Sir J. Hawkins, 'the representations of the genera and their species, as well by diagrams as in words, are almost as numerous as the writers on music.' To that erudite historian of music we refer the reader who wishes for more information on a subject in which so few now take the slightest interest. The modern diatonic and chromatic genera, or scales, are probably much the same as, or nearly allied to, those of antiquity. Our Enharmonic is, practically—at least on most instruments—but a convenient evasion, the mere bestowal of two names on one and the same sound.

GENERAL, a title conferred on military men above the rank of field-officers. In all the states of Europe it indicates the commander-in-chief of the forces of the nation; the commander of an army or grand division, and also those who, under the latter, exercise his functions, with the particular designations of lieutenant-general and major-general.

The origin of the title appears in the history of France, in which country it seems to have been conferred on the commander of the royal army about the middle of the fifteenth century, when something like a regular military force was first established in Europe. The kings were then considered as holding the chief command of the army in virtue of their birth; and, on appointing persons under them to exercise a general superintendence of the forces, they gave to such officers the title of *lieutenant-general*, in order to designate at the same time the extent of their duties and their dependence on the sovereign whom they represented. By a decree made in the year 1450, in the reign of Charles VII., John, count of Dunois, was so qualified; and the title of lieutenant-general, denoting the immediate commander-in-chief of an army, was long retained in the French service. In the course of time, by an abbreviation in language, the prefix of the title was omitted, and the term *general* alone was applied to persons holding such command.

Previously to the epoch above mentioned the title of Grand Sénéchal of France appears to have conferred the right of commanding the royal armies; but the dignity being hereditary in the counts of Anjou, when that province passed to the crown of England in the reign of Henry II., the right ceased, and the kings of France delegated their authority to noblemen chosen at pleasure. In 1218 Philip Augustus conferred the command on Mathieu de Montmorenci, the constable of France; and the successors of that high officer held it till the re-formation of the army in the reign of Charles VII.

It must be remarked, however, that at a period more early than that of the creation of lieutenant-generals under the sovereign, the title of captain-general had been conferred on certain officers with military jurisdiction over particular districts. This species of command is supposed to have been first instituted in 1349 by Philip of Valois, who placed Guy de Nêle, already Maréchal de France, over the district of Xaintonge; within which he was authorised to inspect the castles and fortified towns, and to superintend all the military affairs. The nature of the duty therefore seems to have resembled that of the inspecting field-officers now appointed to particular divisions of this country and the colonies. But in 1635, that is, about eight years after the suppression of the post of constable of France, Louis XIII. gave the title of captain-general, for the army of Italy, to the duke of Savoy; and this appointment was precisely that of commander-in-chief, since it placed the duke above the maréchal de Créqui, who was previously at the head of the army.

It is about this time that the term lieutenant-general, in the sense which it now bears, first appears. For, according to Père Daniel, who quotes the history of Cardinal Richelieu for the fact, when the prince of Condé was made commander-in-chief of the army destined against Spain, the Marquis de la Force was appointed his *lieutenant-general*, and M. de Fouquières held the same rank under the Duc de Longueville, who was to act with an army in Franche-Comté. We have here but one lieutenant-general for each army: but the writer above mentioned observes that, during the reign of Louis XIV., the armies of France being much more numerous than before, the officers were also greatly multiplied; and adds that, in 1704, there were more than sixty who had the title of lieutenant-general.

The title of captain-general above mentioned must not be confounded with that which was created by Cardinal Riche-

lieu, in 1656, in favour of the Marquis de Castelnaut: this officer was placed above the lieutenant-generals of the army, but was subordinate to the marshal of France, who commanded in chief; and it appears that some of the former having retired from the service in disgust, in consequence of the new appointment, the cardinal was obliged to create others in their places.

In the reign of Francis I. the title of colonel-general was instituted; and it was first in 1544 conferred on M. de Taix, with the command of all the infantry of the nation. The title existed however only to the time of Louis XIV., by whom it was abolished.

The English nation has nearly followed the practice of France in matters appertaining to the military service. Thus the lord-high-constable and the lord-marshal of England, in former times, were at the head of the military establishments of the country; and, when the first office was suppressed by Henry VIII. in 1521, the title of captain-general appears to have been adopted for the commander-in-chief. This title occurs in the list of the army which served at St. Quintin in 1557, of which list a copy is given by Grose from a MS. in the British Museum. From the same list it appears that a lieutenant-general for the whole army was immediately subordinate to the former; and that under the last was a general of horse, a captain-general of foot, with his lieutenant, and a sergeant-major (corresponding to a present major-general). But the title of captain-general probably did not long remain in use; for, in the list of the army raised by Elizabeth in 1588, the highest officer is styled lieutenant-general, the queen herself being probably considered as the commander-in-chief. In the army which, in 1620, it was proposed to raise for the recovery of the Palatinate, and, in that raised by Charles I. in 1639, the commander is entitled the lord-general; a lieutenant-general appears as the second in command, and the third is designated serjeant-major-general. It was probably soon after this time that the last officer was called simply major-general; for we find that in 1656 Cromwell appointed twelve officers under that title to have civil and military jurisdiction over the counties of England. (Clarendon, b. 15.)

It is evident, from the histories of the northern states, that the armies in that part of Europe have always been commanded nearly in the same manner as those of France and England. Sir James Turner, who wrote his 'Military Essayes' in 1670, states that in Germany, Denmark, and Sweden, the commander-in-chief was designated feld-marshal, and that he had under him lieutenant-generals of the whole army, besides generals and major-generals of horse and foot. With respect to the first title, he considers it to have been granted, as a more honourable distinction than that of lieutenant-general, only within about fifty years from his time; and he appears to ascribe the introduction of it to the king of Sweden (Gustavus Adolphus), who, when he invaded Poland, thought fit to gratify some of his generals by designating them lieutenant-feld-marshals. (*Pallas Armata*, ch. 13.) From that time, both in Germany and Great Britain, such title, omitting the word lieutenant, has been considered the highest in the army.

In France, during the reign of Louis XIV., and perhaps at an earlier time, the naval commander immediately below the rank of vice-admiral was entitled lieutenant-general. A similar designation seems to have been early employed in the English service, for in the time of Queen Elizabeth the commander of a squadron was called the *general*; and, as late as the time of the Commonwealth, a joint commission of admiral and general was given to Blake and Mountague, though the expedition on which the fleet was sent was confined to an object purely naval.

The administration of military affairs in the great nations of Europe becoming highly complicated during the eighteenth century, the commanders-in-chief, even when not actually on the field of battle, found themselves fully occupied with the higher departments of the service; and it became indispensable that the number of subordinate generals should be increased, in order that all the steps which were to be taken for the immediate security of the armies, and for the acquisition of the necessary supplies, might be duly superintended by responsible officers. The division of an army, for the purpose of occupying important positions or of obtaining subsistence, led also to the appointment of several distinct commanders, each of whom required his own particular staff; and this circumstance, added to the necessity of having a number of officers prepared at once to assume the command of troops when circumstances should require it, will explain why military men holding the rank of general appear now to be so numerous.

In the British service there are about 75 full generals, and about 360 lieutenant and major-generals; but of this number many command particular regiments as colonels, or hold military governments in the country and colonies; many of them have only local rank; and many have retired from the service, retaining the title, but without receiving the pay or being qualified for obtaining any progressive promotion.

The *staff* of the whole military force of Great Britain consists of the general commanding-in-chief, the adjutant-general, and the quartermaster-general.

The duty of the adjutant-general falls partly under that of the sergeant-major-general in the sixteenth century: in the field he receives the orders from the general officer of the day, and communicates them to the generals of brigades; he makes a daily report of the situations of all the posts placed for the security of the army; and, in a siege, he inspects the guards of the trenches.

The quartermaster-general corresponds in part to the harbinger of the army in the sixteenth century. This officer has the charge of reconnoitring the country previously to any change being made in the position of the army; he reports concerning the ground which may be favourable for the site of a new encampment, and upon the practicability of the roads in the direction of the intended lines of route. He also superintends the formation of the encampment and the disposition of the troops in their cantonments.

The first notice of a commander of the artillery occurs in the time of Richard III.: this officer was designated simply master of the ordnance till 1603, when the earl of Devon was dignified with the title of general. The head of this department is now styled master-general of the ordnance.

GENERAL ASSEMBLY OF THE CHURCH OF SCOTLAND. This is the Scottish ecclesiastical parliament; it is a representative, legislative, and judicial body, which differs essentially in its constitution from the Convocation of the English church [CONVOCATION], in being composed of representatives of the laity, as well as of the clergy; and, therefore (like the British House of Commons), may be considered as a delegation from its constituency, the church. [CHURCH.] The following is the composition of the General Assembly:—

Eighty presbyteries, each of which consists of a certain number of parishes, varying from six to thirty-six, send to the Assembly 218 ministers and 94 elders; the city of Edinburgh sends 2 elders, and 65 other royal burghs send each one elder; the four universities send each a representative, and an additional one is sent from Marischall college, Aberdeen—these five may be either ministers or elders; one minister and one elder represent the churches in India in connexion with the church of Scotland. The kirk of Scotland has 1023 parishes, with 1050 ministers.

The General Assembly meets annually, in the month of May, in Edinburgh. The session lasts only ten days; but special business not decided within the period of the session may be referred to a commission, which is, in fact, the Assembly under another name; the commission can hold quarterly meetings. The speaker, or president of the assembly, is called moderator; he is chosen annually, and is, in modern times, a clergyman, it being a rule that the moderator should preach a sermon before the opening of the Assembly; but laymen have occasionally filled the chair. [BUCHANAN, GEORGE.]

Each parish in Scotland has its kirk session, composed of the minister and lay elders of the parish, which manages the parochial business. From the decision of the kirk session there is an appeal to the presbytery in which the parish lies. Each presbytery is composed of the ministers and elders of a certain number of parishes; but the presbyteries vary considerably in the number of parishes of which they are formed. A higher court, called a synod, is composed of two or more presbyteries. From the decision of a synod an appeal lies to the General Assembly, whose decision is final. The functions of the Assembly are analogous to a combination of the functions of both houses of

parliament. Its members speak and vote; it judges all matters connected with the government of the church; and it can proceed judicially against any member of the church, clerical or laical, for alleged impropriety or inconsistency of conduct or doctrine.

The connexion of the Church of Scotland with the State is indicated in the General Assembly by the presence of a functionary, who, under the title of lord-high-commissioner, represents the king or queen. The Scottish church however does not recognise the king or queen as head of the church, but as head of the state, with which the church is allied, for purposes of protection and civil authority. The lord-high-commissioner has no voice in the assembly; business is not necessarily interrupted by his absence; and his presence merely implies the sanction of the civil authority. On the conclusion of the session of the General Assembly, the moderator, after mentioning the day in the following year on which the Assembly meets again, dissolves the meeting in the name of the Lord Jesus Christ, the head of the church (sometimes the words 'the only head' are used), and then the lord-high-commissioner adds the sanction of the civil authority by appointing in the name of the king or queen the Assembly to meet on the day named by the moderator.

GENERALISSIMO, the commander-in-chief of an army which consists of two or more grand divisions under separate commanders. The title is said by Balzac to have been first assumed by Cardinal Richelieu, when he led a French army into Italy, and it has been since occasionally given to officers at the head of armies on the Continent, but it has never been adopted in this country.

GENERATING FUNCTIONS. The term *generating function* is a name given by Laplace to any function of x, considered with reference to the coefficients of its expansion in powers of x, as follows: if

$$\phi x = \psi 0 + \psi 1 . x + \psi 2 . x^2 + \ldots + \psi n . x^n + \ldots .$$

then ϕx is the generating function of ψn. Thus the generating function of n is $x \div (1-x)^2$, since the coefficient of x^n in the expansion of the preceding is n.

The theory of Generating Functions was investigated by Laplace, and it may be found in his 'Théorie des Probabilités,' or in Lacroix, 'Treatise on the Differential Calculus' (in the third volume of the quarto edition), or in the Appendix to the Cambridge translation of Lacroix. Its principal use is in the solution of equations of differences, and in the deduction of theorems connected with that subject.

GE'NESIS, THE BOOK OF, is the first of the five books of Moses, and derives its name from the principal event recorded in it, namely, the creation of the world and the human race, which in the Septuagint Greek translation is expressed by the word *Genesis* (Γένεσις) 'creation' or 'production.' In the original Hebrew it is named, according to the usual custom, from the first word in the book, *Bereshith* (בראשית) 'In the beginning;' it is not unfrequently cited by the Rabbins as *Sepher Yezirah* (ספר יצירה) 'The Book of the Creation;' and Josephus in his treatise against Apion (i. 8) called it 'the account of the creation of man,' (ἡ τῆς ἀνθρωπογονίας παράδοσις).

It has been thought by many critics that the Book of Genesis was not written by Moses. There are some passages in it which evidently could not have been the composition of Moses, since they refer to events which happened after his death. See c. xiii. 18, c. xxiii. 2, and c. xiv. 14, where Hebron and Dan are mentioned, which, we learn from other parts of the Bible, had different names in the time of Moses. See also Gen. xxxvi. 31, where an allusion is made to the kings of Israel, and a list is given (31—43) of the princes of Edom which is the same as the list given in Chronicles, I., c. i. 43—54. But these and similar passages might easily have been inserted in later times. Dr. Graves in his *Lectures on the Pentateuch*, and Faber in his *Horæ Mosaicæ*, vol. i. p. 305—336, show that there is no other period in the history of the Jews to which its composition can be so well referred. The preface to the first volume of the last edition of Rosenmüller's *Scholia* contains a fair view of the controversy; in which he gives many reasons for relinquishing the opinion he formerly held, that the book of Genesis was not written by Moses.

Supposing Moses to have been the author, it becomes an interesting question to ascertain in what manner Moses was enabled to give a faithful history of events which happened so many centuries before his own age. The book must have been composed in one of three ways: 1st, by immediate revelation of every circumstance from God; 2nd, by a collection of antient traditions; or 3rd, from former documents. The first supposition is generally abandoned in the present day by all theologians, with the exception of those who believe in the verbal inspiration of the Scriptures. The second, which is a common opinion amongst theologians in this country, would not injure the credibility of the book; since Lamech, the father of Noah was contemporary with Adam, Shem the son of Noah lived in the time of Abraham, his son Isaac was contemporary with Joseph, and some of the contemporaries of Joseph might have known Moses; so that few persons were required for the transmission of the traditions. The third opinion is the one generally received by the German theologians of the present day, and was maintained by many former writers. (See Carpzov., *Introd.*, part i. p. 57; Vitringa, *Observ. Sacr.*, l. i., dissert. i., c. 4.; Le Clerc, *Proleg.*, dissert., iii. p. 30; Calmet, *Commentaire Littéral*, vol. i., part i., p. 13.) Astruc believed that this book of Moses was composed from twelve such documents. (*Conjectures sur les Mémoires Originaux dont il paroit que Moise s'est servi pour composer le Livre de Genèse*, 1753.) Ilgen reduced the number to three (*Die Urkunden des ersten Buchs von Moses in ihren Urgestalt*, 1798); and Eichhorn in his 'Introduction to the Old Testament,' vol. iii., p. 42—135, maintains there were only two. There is however considerable difficulty in assigning the number, though there are strong reasons for believing that the general hypothesis is correct. Our limits will only permit us to give two examples. It is supposed that the first three chapters were composed from two separate documents; one containing the first chapter and the first four verses of the second, the other the remainder of the second chapter and the whole of the third. The second document, which begins with the words, 'These are the generations of the heavens and the earth,' contains another account of the creation, which would hardly have been given again after the full account of the same event in the first chapter, if all three had been written by one person. In addition to this, the name of the Deity is different in the two documents; in the first he is invariably called *Elohim* (אלהים), and in the second *Jehovah Elohim* (יהוה אלהים). The frequent repetition of the same circumstances in the history of the Deluge have induced critics to believe that it was composed from two documents. Compare vi. 5, with vi. 12; vi. 9, with vii. 1; vi. 19, 20, with vii. 2, 3; vi. 17, with vii. 4; vi. 22, with vii. 5; vii. 6—9, with vii. 11—16; vii. 18, with vii. 19; vii. 21, 22, with vii. 23; viii. 21, 22, with ix. 8—11. The whole of the book of Genesis is divided by Eichhorn, in his 'Introduction to the Old Testament,' and by Jahn, in his 'Hebrew Bible,' (Vienna, 1806), into the original documents from which they believed it was compiled. Dr. Lamb, in his work on 'Hebrew Letters taken from Hieroglyphics,' supposes, without a shadow of reason, that Moses copied the first eleven chapters from hieroglyphics.

The book of Genesis may be divided into two parts; the first extending from the beginning of the book to the 9th verse of the 11th chapter, and the second containing the remaining chapters. The object of the author was to give the history of the Jews from the earliest times; and the first part, which contains the history of the world from the creation to the birth of Abraham, is merely introductory. The real history commences with his birth, preceded by a genealogical table of his pedigree.

I. The first part (i.—xi. 1—9,) gives an account of the creation and of the institution of the Sabbath (i. ii. 1—3); of the fall of man and his expulsion from Paradise (ii. 4—25, iii.); of the history of Adam and his descendants till the Deluge (iv. v.); of the Deluge (vi. vii.); of the restoration of the world (viii.); of the history of Noah and his sons (ix.); of the peopling of the world by his descendants (x.); and of the confusion of tongues and dispersion of mankind (ix. 1—9). Many theologians, from a supposed difficulty in the literal interpretation of the first three chapters, have supposed them to be *mythical*. The arguments for such a mode of interpretation may be seen in Seiler's *Biblical Hermeneutics*, transl. by Dr. Wright, p. 163—169. To this it is replied that the style is purely historical, that the difficulties are imaginary, and that the writers of the 'New Testament' refer to the events contained in the first three chapters as real transactions. (Mat. xix. 4; John viii. 44; 1 Tim. ii. 13, 14; 2 Cor. xi. 3; 1 John, iii. 8.)

The positive enactments of the patriarchal religion were few and were all retained in the laws of Moses. They related to the Sabbath (ii. 3; viii. 10—12), to sacrifices (iv. 3, 4), and to abstinence from the flesh of animals with the blood in it (ix. 3, 4).

II. The second part (xi. 9, to the end of the book) gives an account of the family of Abraham and his journeys into Canaan and Egypt (xi. 10—32, xii.); of the wanderings of Lot and Abraham in Canaan (xiii.); of the defeat of the four kings by Abraham (xiv.); of the promise of God to Abraham (xv.); of the birth and early life of Ishmael (xvi.); of the institution of circumcision and the renewal of the promise (xvii.); of the destruction of Sodom and Gomorrah (xviii., xix.); of the sojourning of Abraham at Gerar and the birth of Isaac (xx., xxi.); of the trial of Abraham (xxii.); of the death of Sarah (xxiii.); of the marriage of Isaac (xxiv.); of the birth of Esau and Jacob (xxv.); of the history of Isaac (xxvi., xxvii.); of the departure of Jacob to Padan-Aram, and of his return to Canaan (xxviii.—xxxiii.); of the cruelty of Simeon and Levi to the Shechemites (xxxiv.); of the death of Isaac (xxxv.); of the history of Esau and his descendants (xxxvi.); of the selling of Joseph into Egypt (xxxvii.); of the incest of Tamar (xxxviii.); of the history of Joseph in Egypt (xxxix.—xlv.); of the descent of Jacob into Egypt, and his settlement there with his family (xlvi.—xlix.); and of the death of Jacob and Joseph (l.).

The chronology of the book of Genesis has occasioned great difficulty. This arises from the difference of the Hebrew text from the Septuagint. According to the Hebrew text the deluge happened A.M. 1656, according to the Septuagint A.M. 2262; the former giving B.C. 4004, and the latter B.C. 5411, as the epoch of the creation. Dr. Hales, with many other critics, considers the dates of the Septuagint to be more in accordance with profane history and with the various events related in the first chapters of Genesis. Our limits prevent us from giving an account of the controversy; we can only refer to the arguments in Dr. Hales' *Analysis of Chronology*, vol. i. 273—303, and Clinton's *Fasti Hellenici*, vol. i., p. 283—301; the latter of whom defends the chronology of the Hebrew text, and observes with much justice that there does not appear any sufficient reason for inducing the Jews to change the numbers, while the translators of the Septuagint were naturally anxious to make the epoch of the creation more conformable with the high pretensions of the Egyptians and Chaldæans. From the Deluge to the common date of the birth of Abraham, the Hebrew text gives 292 years, the Septuagint 1072. This date is given on the authority of Gen. xi. 26, 'And Zerah lived 70 years, and begat Abram, Nahor, and Haran.' But there is sufficient reason for believing that Abraham was not born till 60 years afterwards, and that his name is only placed first on the catalogue on account of his celebrity, not because he was the first-born. Adding 60 years to the former numbers we obtain the birth of Abraham, according to the Hebrew text A.M. 2008 or B.C. 1996; according to the Septuagint, as corrected by Dr. Hales and Mr. Clinton, A.M. 3258 or B.C. 2153. Having obtained the birth of Abraham, there is no great difficulty in ascertaining the dates of the principal events that follow. The following table is abridged from Clinton's 'Fasti Hellenici;' the dates are reckoned from the birth of Abraham:

Birth of Abraham, in 130th year of Zerah. Gen. xi. 32, xii. 3—5, compared with Acts vii. 4.

10. Birth of Sarah, ten years younger than Abraham. Gen. xvii. 17.
75. The call of Abraham. Gen. xii. 1—4.
86. Birth of Ishmael. Gen. xvi. 16.
100. Birth of Isaac. Gen. xvii. 17.
137. Death of Sarah, at the age of 127. Gen. xxiii. 1, 2.
140. Marriage of Isaac, at the age of 40. Gen. xxv. 20.
160. Birth of Esau and Jacob. Gen. xxv. 26.
175. Death of Abraham. Gen. xxv. 7, 8.
237. Jacob goes to Haran at the age of 77.
257. Jacob returns to Canaan. Gen. xxxi. 41.
268. Joseph, at the age of 17, sold into Egypt. Gen. xxxvii. 2.
280. Death of Isaac, at the age of 180. Gen. xxxv. 28.
281. Joseph, at the age of 30, governor of Egypt. Gen. xli. 46.
290. Jacob, at the age of 130, goes into Egypt. Gen. xlvii. 9.
307. Death of Jacob, at the age of 147. Gen. xlvii. 28.
360. Death of Joseph, at the age of 110. Gen. l. 26.

The following passages are supposed by most Christian divines to be prophecies relating to Christ:—iii. 15; xii. 3; xviii. 18; xxii. 18; xxvi. 4; xxviii. 14; xlix. 10.

(Eichhorn's *Einleitung in's Alte Testament*, vol. iii. p. 18—176; Augusti's *Grundriss einer historisch-kritischen Einleitung in's Alte Testament*, p. 157—162; Faber's *Horæ Mosaicæ*; Graves *On the Pentateuch*; Rosenmüller's *Scholia*; Holden's *Dissertation on the Fall of Man*; Horne's *Introduction to the Scriptures*, vol. iv. p. 3—9.)

GENESSEE. [NEW YORK.]

GENETTA (Zoology), Gennet. [VIVERRIDÆ.]

GENE'VA, GENE'VE (*Genf* in German, *Ginevra* in Italian), a town and canton of the Helvetic Confederation, situated at the south-west extremity of Switzerland, is bounded on the north by the canton of Vaud and the Leman Lake, on the east and south by Savoy, and on the west by the French department De l'Ain. It consists of the territory of the old republic of Geneva, of the district of Versoix ceded by France, and of the districts of Carouge, Hermance, and others, ceded by the king of Sardinia by the treaties of Paris, 1814, and of Turin, 1816. The area of the canton is reckoned at about 93 square miles, it being the smallest canton in Switzerland, though by no means one of the lowest, either in population, industry, wealth, or political importance. The population of the canton amounted, according to the census of 1834, to 56,655 inhabitants, of whom 27,177 were in the town of Geneva. Of the inhabitants of the town about 17,000 were Genevese by birth, 5000 were Swiss of other cantons, and the rest were natives of France, Savoy, Italy, Germany, and other countries, among whom were two or three hundred English. The greatest length of the canton is about 17 miles, from Hermance, on the extreme north-east frontier, towards the Chablais, to Chancy, a commune on the left bank of the Rhône, south-west of Geneva, near the Fort de l'Ecluse, which is a French military outpost on that side.

The territory of Geneva extends along both banks of the lake and the valley of the Rhône, being confined on the west by the lower offsets of the Jura, and on the east and south-east by the mountains of Voirons and Salève, which are about 4000 feet above the sea. These mountains however are out of the territory of Geneva, which contains only some hills, the highest of which are not 400 feet above the level of the lake. The territory of the canton is divided into three districts:—1. The district north of the Rhône, including a strip of land along the west bank of the lake as far as the borders of the canton of Vaud, beyond Versoix. 2. The district south of the Rhône, and between it and the left bank of the Arve, which includes Carouge, a neat well-built town, with 4000 inhabitants, about one mile south of Geneva. 3. The district north of the Arve, and between it and the east bank of the lake, along which it extends in a narrow strip as far as Hermance. The principal place of this last district is Chesne, consisting of two large villages adjoining each other, which reckon together about 2000 inhabitants. Numerous other villages are scattered about the whole territory; and the immediate neighbourhood of Geneva, both along the banks of the lake and in the direction of the principal avenues leading to the town, exhibits extensive lines and groups of country-houses, which form handsome suburbs.

The territory of Geneva, though not naturally fertile, is rendered productive by the industry of the inhabitants: about one-third of it is sown with corn, another third is pasture-land, a much smaller proportion is planted with vines, which yield an indifferent sort of wine; the rest consists of woods, orchards, and gardens. In 1835 there were about 7650 head of cattle. The deficiency in corn, cattle, and wine, for the consumption of the town of Geneva, is supplied by the neighbouring countries.

Manufactures, and the employment of capital in foreign funds, banking and exchange, and commercial speculations, form the principal sources of wealth of the Genevese. There are among them many capitalists; and Geneva, which is the most populous town of Switzerland, is also the wealthiest, with the exception perhaps of Basel. Industry, calculation, and economy are characteristics of the people in general. Watches and jewellery are now the principal manufactures: about 100,000 watches are made annually and exported to France, Italy, the Levant, and other countries. This branch of industry employs nearly 2000 individuals, and jewellery nearly 1000 more. There are in

the town about 1600 tradespeople, and about 2500 servants, of whom 1900 are foreigners, chiefly from Savoy and the canton De Vaud.

Three-fifths of the population are of the Reformed or Calvinist communion; the rest are Catholics, the number of whom, formerly consisting chiefly of foreign residents, has much increased since 1814 by the incorporation of the ceded districts of France and Savoy. The town of Geneva is divided into 14 parishes; and the old territory of the republic, which is mostly inhabited by Protestants, into 14 more. The Catholic rural districts contain 28 parishes, which are included in the diocese of Freyburg, whose bishop styles himself bishop of Lausanne and Geneva. In the town of Geneva there is a Catholic church, the curate of which superintends the Catholic families scattered about the town. The Jews have a synagogue at Carouge, but they have not the freedom of the city of Geneva.

The roads of the canton are kept in very good order by the State Government, at the annual expense of 136,000 florins (the Geneva florin is about 4½*d.*). The other principal heads of expenditure are administrative and judicial departments, 310,000 florins; support of the Protestant clergy, 135,000; ditto of Catholic clergy, 92,000; public instruction, 230,000; military, 525,000, police and prisons, 200,000; pensions, 30,000; emoluments of the deputies to the Diet and other expenses for federal objects, 30,000; public works, 90,000 florins. The revenue of the canton amounts to about 2,000,000 florins, derived from the following sources: land and house-tax, 204,000 florins; stamps, registry of sales, and deeds and mortgages, and legacy-duty, 950,000; income tax, called tax des gardes, 189,000; post-office, 169,000; customs, 144,000; monopoly of salt, 214,000; tax upon servants, 45,000; patents and licenses, 35,000; tolls at the gates, 39,000. All this is exclusive of the municipal taxes of the city of Geneva.

There are 41 elementary schools in the various communes of the canton, attended by about 3860 children. For administrative purposes the canton, exclusive of the capital, is divided into 37 communes, of which 15 belong to the old territory of the republic, 16 have been dismembered from Savoy, and 6 ceded by France. In every commune there is a municipal council, elected by the inhabitants above 21 years of age, and who pay at least two florins of direct taxes. The council is presided by the maire, who is appointed by the council of state.

The canton is bound to furnish to the Swiss Confederation, when summoned by the Diet, a contingent of 2 battalions of infantry, 3 companies of artillery, and a company of cavalry; in all, 1760 men. The militia of the canton, including all citizens from 20 to 45 years of age, and amounting to about 5500 men, is exercised and reviewed every year. Besides these there is for the service of the town and the police a garrison of 120 salaried artillery-men, and 80 gendarmes, almost all foreigners. The arsenals of the canton contain 79 pieces of artillery, and 3900 muskets.

Geneva is one of the oldest sites in Western Europe. It is mentioned in the Gallic War of Cæsar (1. 7).

The republic of Geneva originated in the municipal government of the town, to which Charlemagne granted certain privileges and franchises, subordinate however to the bishop, who was styled Prince of Geneva and was an immediate feudatory of the empire. Frequent dissensions occurred between the citizens and the bishop on one side, and the counts of Genevois, 'Comites Gebennenses,' or 'Genevensium,' a feudal dynasty grown out of the wreck of the old kingdom of Burgundy, and which ruled the adjoining province of Savoy, which is still called Genevois or Genevese, and of which Annecy is the capital. These counts claimed jurisdiction over the town of Geneva. The line of the counts of Genevois becoming extinct in the fourteenth century, their inheritance escheated to the house of Savoy, who obtained the investiture of it from the Emperor Sigismund in 1422; and hence are derived the claims of the dukes of Savoy over Geneva, claims however never completely enforced. At the Reformation the bishop quitted Geneva, and retired to Annecy, and from that epoch the town governed itself as an independent municipality, and formed an alliance with the Swiss cantons of Bern and Freyburg, and afterwards Zürich. The dukes of Savoy, after several fruitless attempts to reduce Geneva by force or surprise, acknowledged its independence by the treaty of St. Julien in 1603.

In the eighteenth century Geneva was distracted by interior feuds between the popular party, or représentans, and the aristocratic families, or négatifs. [DELUC.] These troubles furnished the French Directory with a pretence for seizing it by force, and incorporating it with France in April, 1798. It then became the head town of the new department 'Du Léman.' In 1814 it was occupied by the Austrians, and was restored by the allied powers to its independence as a canton of the Swiss Confederation, to the great satisfaction of its inhabitants.

The town of Geneva is built on two hills divided by the Rhône, where it issues out of the Leman lake, the higher of which, on the south bank of the river, is about 100 feet above the lake. The larger part of the town lies on that side. The river forms an island within the town, which is also built upon and is a separate district, joined to the two banks by bridges. The district on the north bank is called St. Gervais. A smaller island, at the very point where the Rhône issues from the lake, is planted with trees and forms a public promenade, which is adorned with the statue of Rousseau. A handsome suspension-bridge has been lately thrown across the river to connect both banks and the island. A handsome quay with fine buildings has also been constructed along the south bank of the river. The streets in the old part of the town, or cité, as it is called, are narrow and steep, the houses high, and the appearance of the streets rather gloomy. The most remarkable buildings are, 1, the church of St. Peter, the handsome front and portico of which were restored in the 18th century; 2, the Hôtel de Ville, which is a very old and massive building; 3, the hospital; 4, the Musée Rath, which has some good paintings; 5, the College, with a library of 50,000 volumes; 6, the Botanic Garden; 7, the Observatory; 8, the new Hôtel des Bergues, one of the largest and finest in Europe; 9, the Penitentiary, where a strict discipline is enforced; the convicts work together in silence, and are separated for the night. The illiterate are taught to read and write There is another prison for individuals waiting for trial, or condemned for misdemeanors by the correctional police. The town is regularly fortified with ramparts, ditches, and bastions, but is commanded by the hills of La Batie and St. Jean, which makes it unfit to stand a regular siege. There are three gates, two on the Savoy or south side, and one on the French or Swiss side.

The municipal expenditure of the town amounts to about half a million of florins annually, the revenue being derived chiefly from the octroi, or duty on provisions levied at the gates. Geneva abounds with means of instruction. There is the Academy or University, with four faculties—theology, law, sciences, and belles lettres, with forty professors; the schools of drawing and architecture, mechanic schools (écoles industrielles) where they teach mathematics, physics, and chemistry, applied to the arts; a school for music; a school of gymnastics; a school for watchmakers' apprentices; besides elementary schools, infant schools, and other schools both public and private. There are also societies of arts, of medicine, of physics, and natural history, a mechanics' society, a military society, and a reading society, which has a library of 30,000 volumes, receives foreign journals and papers, and has about 300 subscribers; a museum of natural history, which is very rich; a cabinet of medals, a botanical garden, under the direction of Professor De Candolle, and other scientific institutions.

It would be difficult to name a town of equal size which has produced so many illustrious men as Geneva. The most distinguished names are those of Turretin, Diodati, Tronchin, Burlamaqui, Godefroi, Leclerc, Bonnet, Saussure, Deluc, Pictet, Odier, Trembley, Sénebier, Delolme, Dumont, Say, Mallet, Rousseau, Madame de Stael. Among the living are Sismondi, Lullin de Châteauvieux, De Candolle, Huber, the engineer Dufour, Prevost, &c.

The social and moral state of Geneva bears still, after a lapse of three centuries, marks of the strong impression which John Calvin stamped upon it. He found a society disjointed, disorderly, ignorant, and licentious; and left it at his death orderly, religious, moral, and patriotic. A mere speck on the map of Europe, exposed to the political and religious antipathies of its powerful neighbours of France, Savoy, and the Spanish government of Lombardy, an object of the fixed hostility of the Court of Rome, Geneva withstood all attacks through the public spirit of its citizens and the wisdom and policy of its councils. Henry IV. of France protected it. It was assisted by Bern and Zürich against the Dukes of Savoy, and the States of Holland, the Protestant

princes of Germany, and the government of Great Britain interested themselves in its favour. By these means Geneva maintained its political and religious independence, and was looked upon as the rallying point of the Reformed communion in western Europe, so as to be styled by some the 'Rome of the Protestants.' It supplied the Reformed churches of France with pastors and teachers, and when Louis XIV. persecuted his Reformed subjects, many of them found an hospitable asylum within its walls. Religious emigrants from Italy came also to swell the number of its citizens. Even to this day it is considered as a sort of metropolis by the Reformed or Calvinist churches of the Continent. Religious dissent however has broken out within its own bosom. A party of zealous religionists have arisen, who seem to charge the majority of the clergy of Geneva with having forsaken the tenets of their Reformer. This party have their chapels, their own school of theology, and they form an association known by the name of the Evangelical Society. Much has been written upon this controversy, and the clergy of Geneva have had a defender in the Rev. J. L. Pons: 'The Doctrine of the Church of Geneva, illustrated in a series of Sermons preached by the modern Divines of that City,' 2 vols. 8vo., 1832. The clergy of Geneva are under the discipline of a synod, called La Compagnie des Pasteurs, presided by a moderator who is changed annually.

By the present constitution of Geneva the council of state, or executive of twenty-four members, has alone the initiative of laws. The projects of laws are laid before the representative council, consisting of 274 members, which accepts or refuses, and may make amendments, with certain restrictions. The members of the representative council are elected for nine years by all the citizens, that is to say, all the natives of either town or territory above twenty-five years of age, who pay seven florins of direct taxes, and who are neither paupers, bankrupts, nor servants, and have not been condemned in any criminal process. The representative council names the members of the council of state for eight years; it also fixes the annual budget of the canton, and also the municipal budget of the town, and appoints the judges and magistrates. The sittings of the representative council are public. The liberty of the press is guaranteed. (Lereschc, *Dictionnaire Geographique de la Suisse.*)

A good account of the old republic of Geneva, of its domestic troubles and external affairs, is given in Berenger, *Histoire de Genève*. Sénebier has written an account of its learned men: *Histoire Littéraire de Genève*. Cox, in his 'Travels,' has given a sketch of its antient constitution, and numerous other travellers have described the peculiarities of this little state.

Geneva is 33 miles south-west of Lausanne, and 80 miles south-west of Berne.

GENEVA, LAKE. [LEMAN, LAKE.]

GENEVA, a spirituous liquor, which is frequently confounded with gin. It is however a fermented liquor, which bears the same relation to gin as wine does to any distilled spirit. It is procured by the fermentation of the berries of the Juniperus communis. These berries consist of a peculiar saccharine principle (which exists to the amount of about 33 per cent. along with acetate of lime), and a volatile oil, which is contained in ten peculiar cells, which lie close to the seeds; as the oil assumes a resinous state in old berries, these cells may be easily seen in such specimens. The green one-year-old berries contain much more volatile oil, and are to be preferred to the ripe berries. The oil rarely exceeds 1 per cent. From the quantity of sugar which they contain they can easily be caused to ferment and yield a spirit, or vinegar may be made from them. Geneva is a very powerfully stimulating liquor, containing a large proportion of alcohol. The volatile oil having a special action on the kidnies renders it the most proper cordial in cases of dropsy from debility, or even connected with diseased heart, when the system requires support. The flavour is attempted to be communicated to English gin, by adding oil of turpentine to brandy; but it is very inferior.

GENEVRE, MONT. [ALPS.]

GENGIS KHAN was the son of a Mogul chief named Pisoucay or Yesoucay, who ruled over thirty or forty thousand families. He was born A.H. 559 (A.D. 1164), at a place called Blun Yulduck. His original name was Temugin, which he exchanged for that of Gengis Khan, *i. e.* 'Khan of Khans,' when he became the supreme ruler of the Moguls and Tartars.

Gengis Khan was early trained to the art of war. His father died when he was in his fourteenth year; and the neighbouring princes took advantage of his youth to invade his dominions. At this early age he marched in person against his enemies, but was obliged to retreat, and fled for protection to Oungh, the powerful Khan of the Keraites, who was known in Europe under the name of Prester John. [PRESTER JOHN.] Gengis Khan remained for many years in the court of Oungh Khan, who gave him his daughter in marriage, and advanced him to the highest dignities in his kingdom. Gengis Khan at length incurred the suspicions of his patron, and orders were given for his arrest. He escaped this danger, and returned to his own dominions, where he defeated the troops that were sent against him, and persuaded many of the Mogul hordes that were subject to Oungh Khan, to rebel against his authority. Oungh Khan marched in person against them, but was entirely defeated by Gengis Khan, A.H. 599 (A.D. 1202), who obtained the dominions of his father-in-law in consequence of this victory. He next conquered the Naimans, and compelled the most celebrated of the Mogul and Tartar chiefs to submit to his authority. Having thus united the various hordes that wander over the steppes of Central Asia, he summoned a great council consisting of Mogul and Tartar chiefs, in which he was proclaimed *Khan* of the whole nation, A.H. 602 (A.D. 1205). In the same assembly he disclosed his intention of invading China and Southern Asia, and pretended to have received from heaven a commission for the conquest of the world. With this object in view, he published a code of laws, and introduced stricter discipline into the army, which he divided into bodies of tens, hundreds, thousands, and tens of thousands; called respectively in the Mogul language *Dehe*, *Sede*, *Hezare*, and *Toman*. Before he could carry his projects into effect, he was obliged to defend himself against those Mogul chiefs who refused to submit to his sovereignty. These chiefs were subdued in the course of five years; and Gengis Khan was at length able to commence his career of conquest. China first experienced the devastations of the Moguls, A.H. 607 (A.D. 1210); but a temporary peace was concluded between the two countries, and the daughter of the king of China was married to Gengis Khan. Three years afterwards another Mogul army invaded the country, and after defeating the Chinese, took the city of Pekin. The northern provinces of China were from this period annexed to the Mogul empire.

The most powerful monarch in southern Asia at this time was Mohammed Kothbeddin, king of Carizme, whose ancestors had established an independent monarchy on the decline of the power of the Seljuke Sultans. [SELJUKIDES.] He ruled over almost all the countries of southern Asia from Syria to the Indus, and had demanded of the Abbaside Caliph to be allowed to reside at Bagdad as *Emîr al Omara*, a dignity which had formerly belonged to the Seljuke Sultans. This demand was refused; and the Caliph fearing the power of Mohammed, sent an ambassador to Gengis Khan to implore his assistance. Gengis Khan did not immediately comply with the Caliph's request; but anxiously waited for some act of hostility on the part of Mohammed to justify him in breaking the peace which then subsisted between them. This was soon given him by the murder of some Mogul ambassadors and merchants at Otrar, a town on the Jaxartes, in the dominions of Mohammed. Gengis Khan collected all his forces, and with an army of 700,000 men, according to Oriental historians, advanced to the Jaxartes, A.H. 615 (A.D. 1218). Near this river he was met by Mohammed with an army of 400,000 men, and though the issue of the battle was doubtful, Mohammed dared not hazard a second contest, but retreated to the south after placing strong garrisons in all the fortified towns. The conquest of Transoxiana was completed in two years, and all its cities taken, after an obstinate resistance. A body of 30,000 men was sent into Khorasan to pursue Mohammed, who escaped to an island in the Caspian Sea, where he died shortly afterwards.

In A.H. 618 (A.D. 1221) Gengis Khan advanced castward and entered the city of Balkh, whose inhabitants he massacred on account of the assistance they had rendered to Gelal-eddin, the son of Mohammed. While he was engaged in the conquest of the neighbouring countries, he sent part of his forces to subdue Khorasan, part to conquer the western provinces of Persia, and an army of 80,000 men to pursue Gelal-eddin, who had fled into the countries west of the Indies. These expeditions were successful, with the

exception of the last. Gelal-eddin, who appears to have been a brave and enterprising prince, defeated the Moguls, but was soon afterwards conquered by Gengis Khan, who had marched in person against him. In the two following years the lieutenants of Gengis Khan conquered Azerbijan and all the other provinces of the Persian empire. In A.H. 620 (A.D. 1224), he again crossed the Jaxartes, and returned to his capital, Cara-corom, after an absence of seven years, during which period he had laid waste the most fertile regions of Asia, plundered the cities of Carizme, Herat, Balkh, Candahar, Bokhara, Samarcand, and many others of less note, and destroyed, according to the calculation of Oriental historians, five millions of human beings. His empire now extended from the Volga to the Pacific, and from Siberia to the Persian Gulf; but he still meditated new conquests, and in the following year led his victorious Moguls through the desert of Gobi against the King of Tangut, whom he defeated and subdued. He then continued his march towards the southern provinces of China, but died on the borders of that country on the 10th of Ramadhan, A.H. 624 (24th August, 1227), in the sixty-fourth year of his age. He was succeeded by his son Octai. His two other sons had the provinces of Transoxiana and Khorasan assigned to them. The Mogul princes have always claimed descent from the family of Gengis Khan; but his descendants lost all real power, though they still retained the title of Khan, in the time of Tamerlane. [TAMERLANE.]

The code of laws published by Gengis Khan is still known in Asia under the title of *Isa Gengis Khani*, 'The Laws of Gengis Khan.' An interesting account of them is given by M. Langlès in the fifth volume of *Notices et Extraits des Manuscrits de la Bibliothèque du Roi*.

(Petit de la Croix's *History of Genghizcan the Great*, Eng. Trans.; De Guignes, *Histoire des Huns*, vol. iii.; D'Herbelot, *Bibliothèque Orientale*, arts. *Genghiz Khan*, *Mohammed Kothbeddin*, &c.; Gibbon's *Decline and Fall*, c. lxiv.)

GENII, called in the East *Ginn* (Arabic جن), are supposed to be a race of beings created from fire, capable of assuming any form and becoming invisible at pleasure. All Moslems are obliged to believe in their existence, since they are said in the Koran (c. vi.) to be created by God. It is imagined that they inhabited this world many ages before man was created, and were governed by forty successive monarchs of the name of Solomon, the last of whom was called Gân Ebn Gân, and that from him they derived their name. It is also said that they frequently rebelled against God, who at length deprived them of their possessions and gave them to man. We learn from the Koran (c. 72) that many of these wicked spirits were converted by hearing Mohammed reading a portion of it, and that those who continue unbelievers (called, in c. 27, *Ifrît*) will be condemned to the fires of hell. They are believed to take great interest in human affairs, and to be the authors of much happiness and misery to mankind. (An interesting account of the superstitions of the modern Arabs respecting Genii is given in Lane's *Modern Egyptians*, vol. i. 283—290; ii. 164—166.)

GENITIVE. [ABLATIVE CASE.]

GENIUS, in its original acceptation, denoted the tutelary god or dæmon which, according to an antient and common superstition, was allotted to every individual at his birth, to guide and rule him during life, to preside over his fortunes and destiny, and eventually to lead him from existence; and it was supposed that the variety observable in the characters and capacities of different men was dependent upon the higher or lower nature of their attendant genii. Afterwards the word came to signify the disposition itself, without reference to its supposed cause; and lastly, in modern times it has been employed, in a restricted but peculiar sense, to designate either that high mental pre-eminence which is occasionally found in a few individuals, or, by a metonymy, the person possessed of such rare excellence.

Like every thing else that is truly beautiful and great, Genius has in it a something undefinable; and hence the variety of notions as to its origin and nature, in all of which there is and must be something deficient. Dr. Johnson's definition ('Life of Cowley,') is this: 'The true genius is a mind of large general powers accidentally determined in some particular direction.' Generally it is understood to be the perfection of human intelligence. And as this consists in the highest possible activity of the mental energies, genius is essentially creative, and all its productions are indelibly stamped with the impress of originality and grandeur. It is at once a law and a model to itself; it produces what has never before been accomplished, and which all, in all ages, are constrained to admire. It receives therefore its impulse from enthusiasm, for nothing great can be accomplished without that enthusiasm which is enkindled by some dominant idea, to which all else is made subordinate and postponed; and its chief faculties are the reason and the imagination, which alone are inventive and productive.

But according as one or other of these faculties predominates, Genius becomes either scientific or artistic. In the former case it seizes at once those hidden affinities which otherwise do not reveal themselves, except to the most patient and rigorous application; and as it were intuitively recognising in phenomena the unalterable and eternal, it produces truth. In the latter, seeking to exhibit its own ideal in due and appropriate forms, it realises the infinite under finite types, and so creates the beautiful.

But even the most eminent genius must duly form and develop itself by a careful contemplation of the beautiful and true which the great geniuses of past time may have created and discovered. It is by looking exclusively to this circumstance, that those who deny any original inequality among men have been led to maintain that what is called genius is simply a result of education and culture; while on the other hand an equally partial consideration of those extraordinary powers which have occasionally been exhibited in totally uneducated minds, and under the most unfavourable circumstances, has deceived the zealous partizans of original genius.

In active life the grand and ambitious designs of successful statesmen and conquerors are often ascribed to genius, but they belong more properly to the energy of the will than to that of the intellect, to force of character rather than to power of mind.

The phrase 'universal genius,' in order to be legitimate, requires to be limited in one or other of its terms. When applied to a Fontenelle we must restrict the signification of genius to the power and capacities of the human mind in general; and it is only by confining the term universal to all the subordinate branches either of art or science, that it is even allowable to ascribe it to the genius of a Michael Angelo or a Leibnitz.

Genius and fancy are often confounded: the latter is undeniably a pre-eminent capacity, but it exerts itself rather to imitate than to invent, and is devoid of all enthusiasm.

Consult Sharpe's 'Dissertation on Genius,' London, 1755; Duff's 'Essays on Original Genius, and its various Modes of Exertion in Philosophy and the Fine Arts,' London, 1767; and 'Lælius and Hortensia, or Thoughts on the Nature and Objects of Taste and Genius,' Edinburgh, 1782.

GENLIS, STEPHANIE FELICITE DUCREST DE ST. AUBIN, COUNTESS DE, was born near Autun in 1746, of a respectable but not rich family. She became at an early age a proficient in music, and her skill as a player introduced her to some persons of distinction, in whose company she had an opportunity of studying the manners and adopting the language of refined society. Her first writings exhibited a remarkable elegance and fluency of diction, which attracted attention, and excited the interest of the count de Genlis, who married her. She was soon after entrusted with the education of the children of the duke of Orleans, and one of her pupils, Louis Philippe, is the present king of the French. In the course of her task, to which she brought great assiduity and zeal, she wrote several works for the use of her pupils, which were afterwards published, namely, 'Les Veillées du Château,' 'Les Annales de la Vertu,' 'Le Théâtre de l'Education,' 'Adèle et Theodore,' &c. These rank among her best and most useful works, and they have had and still have a deserved popularity. After the French revolution broke out, Madame de Genlis, who had been at first its partizan, was obliged to seek safety in flight; she went successively to England, Belgium, Switzerland, and lastly to Hamburg, followed everywhere by the suspicions which her avowed sentiments, her connexions with several leading revolutionists (among others with Lord Edward Fitzgerald, who married her adopted daughter Pamela), and the slander of the royalist emigrants, raised against her. At Hamburg she wrote a kind of political work styled 'Les Chevaliers du Cygne,' which did not add to her reputation either as an author or a moralist. She afterwards attempted

a justification of her own conduct and sentiments, 'Précis de la Conduite de Madame de Genlis.' She returned to France under the consulship of Bonaparte, who had a favourable opinion of her talents, and she became one of his admirers and panegyrists. After her return to Paris she wrote 'De l'Influence des Femmes sur la Littérature,' in which she replied to the attacks of some of the principal literary men of Paris, and Ginguené among the rest; and she also assailed some authors of her own sex—among others, Madame Cottin.

The pen of Madame de Genlis seemed inexhaustible. After the Restoration she wrote in defence of monarchy and of religion; her work, 'Les Dîners du Baron d'Holbach,' which is in a great measure historical, and in which she exposes the weaknesses and the intrigues of the so-called philosophers of the eighteenth century, made a great sensation, and roused the anger of the freethinking party in France. It is a work that contains some curious information. She also wrote 'Dictionnaire Critique et Raisonné des Etiquettes de la Cour,' 2 vols. 8vo., 1818. When she was past eighty years of age she wrote her memoirs. She lived to see the events of July, 1830, and her former pupil raised to the throne. She died on the 31st of December, 1830, aged 84.

Besides the works mentioned above, Madame de Genlis wrote numerous novels, of which those styled 'La Duchesse de la Vallière,' 'Les Battuecas et Zuma,' ou la Decouverte du Quinquina,' are the best. Her works have been published together in 84 volumes, 12mo.

GENNESARET. [PALESTINE.]

GE'NOA, GE'NOVA, a city of Italy, situated on the coast of the Mediterranean, at the foot of the Ligurian Apennines, in the recess of a wide gulf, which extends in the form of a crescent from the frontiers of France to those of Tuscany, and which washes the coasts of the territory of the old Republic. That territory now forms part of the Sardinian monarchy, under the name of Duchy of Genova, and is divided into several administrative provinces,—Genova, Chiavari, Novi, Albenga, San Remo, Savona, and Spezia. The province of Genoa is bounded to the north by that of Novi, east by that of Chiavari, west by that of Savona, and south by the sea, and contains 60 communes and 208,000 inhabitants. It includes the town of Genoa with 94,000 inhabitants within the walls, its extensive suburbs of San Martino with 15,300, and S. Pier d'Arena, 6800; the adjoining valleys of Polcevera and Bisagno; and the maritime towns of Recco, 4000 inhabitants; Nervi, 3300; Pegli, 3000; Sestri di Ponente, 3500; Voltri, 7400; and Arenzano, 2700. The soil is mostly rocky, but the industry of the inhabitants has taken advantage of every spot of cultivated ground. The chief productions are oranges and lemons, light wine, and chesnuts. Maritime trade, fishing, and manufactories constitute the chief resources of the population. The town of Genoa stands partly on the declivity of several hills rising in the form of a semicircle round the spacious harbour, and partly on a narrow strip of ground between them and the sea. It is enclosed on the land-side by a double line of fortifications, the external one being above eight miles in length. The higher Apennines rise immediately behind, dividing the waters which run to the Mediterranean by the valleys of Bisagno and Polcevera, from those which flow northwards into the Scrivia and the Bormida, two affluents of the Po. Upon the summits of these mountains, which are near enough to command Genoa, are several detached forts, called Il Diamante, I Due Fratelli, Sta. Tecla, &c. The appearance of Genoa from the sea is truly magnificent. A succession of fine buildings more than two miles in length lines the shore; numerous palaces and gardens, churches and convents, rise behind like an amphitheatre, on the steep sides of the hills that rear their dark and barren summits above, crowned with formidable ramparts, batteries, and forts; the buildings are square and lofty, and the roofs are covered with light-coloured slate, which has a neat and pleasing effect. The interior of the town is not so pleasant; the streets are very narrow and crooked, dark and steep, with the exception of a few, such as Strada Balbi and Strada Nova, which are entirely lined with marble palaces belonging to the Genoese patricians. Some of these palaces have galleries of paintings, and their internal decorations and furniture are splendid. The palaces Serra, Durazzo, Doria, are among the most remarkable. Genoa has many handsome churches; the cathedral, l'Annunziata, and the elegant church of Carignano, are among the finest. The Loggia de' Banchi, where is the Exchange, the Ponti or quays of the harbour, the Porto Franco or free-port warehouses, where goods can be deposited and re-exported without paying duty; the lighthouse, the new theatre Carlo Felice, built by the late king of that name; the promenade of L'Acquasola, the great hospital, and the former palace of the Doges, are all worthy of notice.

Genoa is a garrison town, the residence of a governor-general, and of a senate or high court of justice for the whole duchy. The French civil and commercial codes have been retained, with some modifications. For public instruction there is the University attended by about 500 students, a Royal college, and six communal schools, one for each district of the town, with very good masters.

The Genoese are shrewd, active, industrious, frugal, and parsimonious. They are well calculated for commerce, which is their real element. The Rivieras or maritime districts furnish the best sailors in the Mediterranean. Genoese vessels trade to the Levant, the Black Sea, the Baltic, to America, and even to the coasts of the Pacific. In 1832 there entered the port of Genoa 2857 vessels, of which 2283 were under the national or Sardinian flag, and of these 427 from the Black Sea, and 648 from beyond the Straits of Gibraltar, including 47 from America. The yearly importations amount to nearly three millions sterling, the exports to somewhat above two millions. The principal articles of export are silk, rice, hemp, oil, and paper. There are at Genoa manufactories of silk stuffs and of woollens, and paper and cotton mills.

The climate of Genoa is healthy, and the atmosphere remarkably pure. Provisions are abundant and at moderate prices. The Genoese speak one of the most difficult Italian dialects, and they have a few books of poetry printed in it.

History of Genoa.—The origin of Genoa, or Genua (its Roman name), is lost in the obscurity of old traditions which would assign to it an antiquity greater than that of Rome. We find it mentioned by Livy (xxi. 32), at the beginning of the Second Punic War, when it appears to have been a town in friendship with Rome. Some years after, Mago, the Carthaginian general, coming with a fleet and army from the Balearic islands to effect a diversion in favour of Hannibal, took Genua by surprise and partly destroyed it. It was restored two or three years after by Lucretius Spurius, after Mago's defeat, agreeably to an order of the Roman senate. (Livy, xxviii. 46; xxx. 1.) From that time Genua appears to have continued in alliance with Rome, but it was not a colony. Strabo (p. 201, Casaub.) mentions Genua as an emporium where the Ligures from the interior brought for sale hides, cattle, honey, and timber for ship-building, and received in exchange oil and wine from other parts of Italy. After the fall of the Western Empire, Genoa was taken possession of by the Langobards, A.D. 641. Charlemagne afterwards took it, and put it, with all maritime Liguria, under the government of a count. After the fall of the Carlovingian dynasty, and during the contests about the crown of Italy between the German emperors and the Berengarii and other claimants, the citizens of Genoa seized the opportunity of asserting their independence under the government of elective magistrates, styled consuls. The names of the consuls began to be recorded from the latter part of the eleventh century. At that time the Genoese had already rendered themselves formidable by sea; after having suffered from the Saracens, who about A.D. 935 surprised and plundered their town, they applied themselves to strengthen their navy, and having allied themselves with the Pisans they drove the Saracens out of Corsica, Capraja, and Sardinia, between the years 1016 and 1021. From that time dates the dominion of Genoa over Corsica and Capraja, and that of Pisa over Sardinia. About A.D. 1088 the united fleets of Pisa and Genoa sailed to the coast of Africa and took Almadia or Mahadia, then an important town between Tunis and Tripoli. They took part in the great Crusade, under Godfrey de Bouillon, and obtained settlements on the coast of Palestine, especially at Acre. In 1146 the Genoese took Minorca from the Moors, and the next year they took by storm Almeria in the kingdom of Granada, where they made an immense booty. The Genoese fleet on this occasion consisted of 63 galleys and 163 transports with 12,000 land forces. In the year after, having joined the Catalonians, they took Tortosa, which was defended by a Moorish garrison. These conquests excited the jealousy of Pisa and Venice, the two other naval powers of Italy; Pisa, being the nearest, was the first to come to blows with Genoa. Four

wars took place between the two states: the first in 1070, which was short; the second in 1118, which was ended in 1132 by the mediation of Pope Innocent II.; the third in 1162, which lasted nearly a century; the fourth in 1282, in which the Pisans were completely defeated by sea near the rocks of Meloria, in sight of their own coast, when 3000 Pisans were killed and 13,000 taken prisoners to Genoa, where most of them died in chains. Pisa never recovered from that blow. In 1290 the Genoese under Conrad Doria destroyed Porto Pisano and filled up the mouth of the harbour.

The rivalry between Genoa and Venice began to show itself soon after the conquest of Constantinople by the Franks in 1244. The Genoese having assisted Michael Palæologus to reconquer his capital, obtained from him the suburbs of Pera and Galata, and the port of Smyrna, with full jurisdiction over those places. The Venetians disputed with them the supremacy of the Levant seas, but after several naval fights the two powers concluded a truce in 1271. After the fall of Pisa the Genoese found themselves more at leisure to renew the conflict with Venice. They put to sea with 165 galleys, each carrying from 250 to 300 men, and sailing up the Adriatic, defeated the Venetians near the island of Curzola, took or burnt 84 galleys, and made 7000 prisoners, including the Admiral Dandolo. Peace was made in 1299, by the terms of which the Genoese excluded the Venetians entirely from the trade of the Black Sea, where the Genoese had formed a succession of colonies, forts, and factories all along the coast. War broke out again in 1346, when the Genoese defeated the Venetians in sight of Constantinople, but were afterwards totally routed on the coast of Sardinia. Genoa, disheartened by this defeat and a prey to internal factions, gave itself up to John Visconti, Duke of Milan. In 1372 war broke out again between Genoa and Venice, for the possession of Tenedos. Genoa had meantime shaken off the yoke of the Visconti. In this, the fourth war between Genoa and Venice, the Genoese took Chioggia and besieged Venice. The Venetians were near capitulating, when Vettor Pisani and Carlo Zeno revived their spirit, formed a new fleet, with which they blockaded the Genoese within Chioggia, and obliged them to surrender. This war, called the war of Chioggia, ended in 1381.

From that time Venice and Genoa remained at peace, with trifling interruptions. Genoa was exhausted by internal factions. To the rule of the consuls had succeeded, about A.D. 1190, that of the Podestà, renewed annually, and who were chosen from among the citizens of another state, in order to avoid the partialities and intrigues resulting from family connexions. This lasted with some interruption till 1270, when two citizens, Oberto Spinola and Oberto Doria, distinguished for their services, usurped the supreme power, under the name of 'captains of liberty,' which they retained till 1291. They reconciled the lower classes to their usurpation by appointing a magistrate called Abate del Popolo, a kind of tribune who supported the rights of the people against the nobles. Foreign captains were next appointed, to be chosen from among the natives of places at least 100 miles distant from Genoa. Afterwards a council was instituted, first of twelve and afterwards of twenty-four members, half nobles and half plebeians. Feuds and fighting often took place within the town between nobles and plebeians, and between Guelphs and Guibelines. Both the Doria and the Spinola were Guibelines, but having quarrelled among themselves they were overcome by the Guelphs, who were headed by the families of Fieschi and Grimaldi, and who exiled their rivals. But the Guibelines of Genoa, unlike those of Florence, were popular among the lower classes, and they re-entered by force. From 1317 to 1331, and again in 1335, these factions continued to desolate the country, so as to render it, says the chronicler Foglietta, a frightful desert. In 1339 the citizens, weary of discord and disorder, instituted a supreme magistrate, called Doge, for life, excluding by law all the nobles, both Guelphs and Guibelines, from ever filling the office. [BOCCANERA; DOGE.] This lasted two centuries, but not without frequent contentions between the principal citizen families, especially the Adorni and Fregosi, who proved just as factious and troublesome as the patricians had been. Several Doges were elected at a time, some were exiled, and others were forced upon the community by an armed faction. The neighbours of Genoa, the Visconti of Milan and the kings of France, taking advantage of these feuds, at various times obtained possession of Genoa. At last, Andrea Doria had the merit of delivering his country from the French yoke; and in order to avoid a recurrence of the former feuds, he changed the institutions of the country, by establishing biennial Doges, and councils to assist and control them. [DORIA.] A roll was made out of all the distinguished families, both noble and plebeian, from among whom the doges, councillors, and other officers of state were to be chosen. This aristocracy however was not wholly closed and exclusive, like that of Venice: new families might be added to it at certain times and with certain qualifications. This form of government lasted from 1528 till Bonaparte's invasion of Italy, when the democratic party, assisted by the French, rose upon the aristocracy, who were supported by the lower classes, and a scene of bloodshed took place which lasted several days, and ended in the discomfiture of the democrats. But the French Directory now took up their part openly, pretending that the honour of the French republic was concerned, and demanded a complete change in the institutions of the country. A democracy was formed, protected by a strong French garrison within the town. In 1799 the French, under Massena, were besieged within Genoa by the Austrians and the English, and after a most gallant defence the town capitulated to the Austrians, but was again given up to the French after the battle of Marengo. Bonaparte, then consul, gave a new form of government to Genoa, leaving to it a sort of nominal independence and the name of republic, but, in fact, he made it less democratic than before. Napoleon, when emperor, in 1805 required the formal annexation of Genoa to France. The Doge Durazzo repaired to Milan, where Napoleon had just been crowned king of Italy, and stated 'the wishes of the Genoese senate and people to be united to the Great Empire.' These wishes were immediately granted. The state of Genoa was formed into the three French departments of Genoa, Montenotte, and the Apennines. In 1814 Genoa surrendered to the English forces under Lord William Bentinck, and in the following year, by a decision of the Congress of Vienna, it was united to the Sardinian monarchy.

Of all her foreign possessions Genoa retained Corsica the longest; till 1768, when she ceded it to France. Her numerous and wealthy settlements in the Levant and the Black Sea she lost after the Ottoman conquest of the Eastern Empire. In the 18th century her navy was reduced to a few galleys, and her flag was insulted with impunity by the Barbary privateers. Since the last peace the spirit of commercial enterprise in her citizens has been greatly revived. The Sardinian navy is chiefly manned by Genoese. (Foglietta, Caffaro, and the other old Genoese chroniclers; Botta, *Storia d'Italia*; Serra, *Istoria dei Liguri e dei Genovesi*.)

GENOVE'SI, ANTO'NIO, born near Salerno in 1712, was ordained priest in 1736, and was made professor of eloquence in the clerical seminary of Salerno. He afterwards repaired to Naples, where he was allowed, through the influence of Monsignor Galiani, archbishop of Taranto, to open a class of metaphysics in that university in 1741. He here then wrote his 'Elements of Metaphysics' in Latin, which he afterwards recast into two Italian works, 'Logica per i giovanetti,' and 'Delle Scienze Metafisiche,' which had great success, and are still much esteemed. His 'Logica' is perhaps the best elementary book of that science in the Italian language. His 'Meditazioni filosofiche sulla Religione e sulla Morale,' are replete with sound judgment, though written in a defective style. In his 'Diceosina, o la Filosofia dell' Onesto e del Giusto,' he proceeds on the principle that 'every thesis in morality is susceptible of logical demonstration.' These are the principal works of Genovesi on the moral sciences. We must now consider him as a political economist. In 1754 Bartolommeo Intieri, a wealthy Florentine merchant, settled at Naples, founded a chair 'of commerce and mechanics,' and with the approbation of the king appointed Genovesi to fill it. This was the first chair of political economy, taken as a distinct science, established in Europe. In the course of his professorship Genovesi wrote his 'Lezioni di Commercio, o di Economia civile,' 2 vols. 8vo. His book is full of sound principles, which were quite new at Naples in his time, although in some instances he still adhered to the Colbert school. His lectures excited a prodigious sensation among the Neapolitans; public attention was at once turned to questions of commerce, arts, and

agriculture; and political economy, the very name of which was hitherto unknown, became quite a fashionable study.

When in 1767 the Jesuits were exiled from the kingdom, the minister Tanucci consulted Genovesi as to a new plan for the organization of the schools and colleges of the kingdom, which he drew up accordingly. He continued to lecture and to write, although his health was greatly impaired for several years, almost to the day of his death, which occurred in September, 1769. The mind of Genovesi is exhibited in the following lines, which he wrote to his friend Angelo Pavesi in 1765: 'I am now getting old, and have nothing more to hope or to expect from this world; but my wish would be to leave my countrymen a little more enlightened than I found them, and also a little more affectionate towards virtue, which is the only true source of good. It is of little use to think about government, arts, or commerce, unless the morals of a nation are also reformed. As long as men will find their interest in being rogues, we must not expect much from our methodic labours.' A selection of Genovesi's familiar letters was published after his death, in two small volumes. He edited in his lifetime the 'Course of Agriculture' of Cosimo Trinci, to which he added notes and a preliminary disco[urse] on the state of Neapolitan agriculture in his time. [Ga]lanti, one of Genovesi's best disciples, wrote an 'Elogio Storico,' or biographical notice of his master, and Fabbroni wrote another in Latin. Ugoni, in his *Letteratura Italiana*, devotes a long article to Genovesi.

GENSERIC, king of the Vandals, was the bastard brother of Gonderic, whom he succeeded A.D. 429. In the same year he left Spain, which had been partly conquered by the Vandals, and crossed over into Africa at the solicitation of Boniface, governor of that province, who had been induced, by the arts of his rival Aetius, to rebel against Valentinian III., emperor of the West. Boniface soon repented of the step he had taken, and advanced to meet the invader. But his repentance came too late. The Moors joined the standard of Genseric, and the powerful sect of the Donatists, who had been cruelly persecuted by the Catholics, assisted him against their oppressors. Boniface was defeated, and obliged to retire into Hippo Regius, where he remained till he obtained a fresh supply of troops. Having ventured upon a second battle, and being again defeated, he abandoned the province to the barbarians, and sailed away to Italy. A peace was concluded between Genseric and the emperor of the West, by which all Africa, to the west of Carthage, was ceded to the Vandals. This however did not long continue; and the city of Carthage was taken by the Vandals by surprise A.D. 439. The emperors of the West and East made great preparations for the recovery of the province; but an alliance which Genseric formed with Attila, king of the Huns, effectually secured him against their attempts.

Genseric's next object was directed to the formation of a naval power; an immense number of ships was built, and his fleets ravaged the shores of Sicily and Italy. Invited by the empress Eudoxia, he sailed up the Tiber (A.D. 455), and permitted his soldiers, for the space of fourteen days, to pillage Rome. In A.D. 460 he destroyed the fleet which the Emperor Majorian had collected for the invasion of Africa; and as his power increased his ravages became more extensive; the island of Sardinia was conquered, and Spain, Italy, Sicily, Greece, Egypt, and Asia Minor, were plundered every year by the Vandal pirates. Leon, the emperor of Constantinople, at last resolved to make a vigorous effort for the recovery of Africa. A great army was assembled, and the command was given to Basilicus. He landed at Bona, and at first met with considerable success, but was at length obliged to retire from the province. After this victory Genseric met with no further opposition, but remained undisturbed master of the sea till his death, which happened A.D. 477. He was succeeded by his son Hunneric. Genseric was an Arian, and is said to have persecuted the Catholics with great cruelty. (Procopius, *De Bell. Vandal.*; Gibbon's *Decline and Fall*, c. xxxiii.—xxxvi.)

GENTIA'NA, a genus of herbaceous plants, giving their name to the natural order Gentianaceæ, remarkable, as ornamental objects, for the brilliant colours and beautiful forms of their flowers, and most useful in medicine, on account of the pure intense bitter which they all contain. The species are extremely numerous, inhabiting the temperate parts of Europe, Asia, and America, chiefly in mountainous situations, where they breathe a pure and rarified air, are exposed to bright light during the short summers of such regions, and although fixed during winter in places intensely cold, yet are so well prepared to resist it by the warmth of their summer, and so much protected by the snow that covers them, as to suffer no injury. These alpine plants are consequently difficult to cultivate, or even uncultivable, from the impossibility of imitating their natural atmosphere; and hence it is only a very small number that are ever seen in gardens. The prevailing colours of their flowers are either an intense pure blue, or a bright clear yellow: some idea may be formed of the brilliancy of the former from that of Gentiana acaulis, a common species in gardens, where it is much employed for making edging to borders; the yellow species are equally represented by Gentiana lutea, a tall kind, which thrives well in a common American border. As the various plants comprehended in the genus Gentiana, as defined by Linnæus, are extremely different in appearance, and offer great diversities of structure in their flowers, some attempts have been made to break the Linnæan genus up into several others. Botanists however have not received these innovations favourably, and therefore, although Dr. Grisebach's new arrangement will probably be adopted, we shall still consider the species as all belonging to one and the same genus.

The ornamental species that are found easily capable of cultivation are G. lutea, with yellow, and G. asclepiadea, saponaria, cruciata, septemfida, acaulis, and Pneumonanthe, with blue flowers. Of these all require a good American border of peat-earth to grow in, with the exception of G. acaulis, which prefers the hardest and stiffest clay. Many other species are named in gardening books, but they generally perish as soon as they are brought under the hands of the cultivator. For medical purposes, the root of Gentiana lutea, a native of the central parts of Europe, is principally collected, especially for the French and English markets; but Gentiana purpurea and punctata have roots that are still more bitter, and the latter is said to furnish the chief part of what is consumed in Germany and the north of Europe. In the Himalayas the roots of Gentiana Kurroo are used as a substitute, and the stems and leaves of G. cheretta.

GENTIA'NA LUTEA, a perennial species, common in the mountainous and sub-alpine districts of Switzerland, Germany, &c. Though the whole plant is bitter, yet as this property is most concentrated in the root, that part only is officinal. This should be taken up in autumn, and is best when the plant is only one year old. It is generally cylindrical, often an inch thick at the summit, but below rather branched, of a dark or brown colour externally; internally fleshy and yellow. In commerce it is met with in pieces, cut longitudinally, from a half to one foot in length. A transverse section displays three distinct circles. The greater portion is procured from Germany; the specimens from Switzerland are generally thicker and darker coloured.

When fresh it has some smell, which is almost entirely lost by drying. The taste is at first somewhat sweet, then purely and strongly bitter. According to the analysis of Henry and Caventou, it contains a principle termed Gentianin, which is crystallizable; a volatile odorous principle, a greenish fixed oil, a free organic acid, uncrystallizable sugar, gum, colouring matter, &c.

Owing to its saccharine matter it soon moulds in a damp place, and should therefore be kept in a dry airy situation. From the abundance of the sugar, it is easily susceptible of fermentation, and from it is distilled a spirit, called Enziangeist, or 'bitter snaps,' much employed by the peasants on the Swiss Alps to fortify the system against the fogs and damps of these lofty regions.

Yellow gentian-root is often confounded with the roots of other species of this genus, a circumstance attended with no bad consequences, but unfortunately roots of very poisonous plants, growing in the same locality, are often taken up instead of the proper one: these are, the Veratrum album (white hellebore), the leaves of which resemble those of gentian in their peculiar venation, but are alternate, while those of gentian are opposite—the root is very different, and besides this, it contains Veratria; and the Atropa Belladonna (deadly night-shade), which, besides differences in the physical characters, is devoid of the peculiar bitter of gentian, and acquires a bluish-black colour from tincture of iodine. The roots of Aconitum Lycoctonum and Ranunculus Thora are occasionally confounded with gentian-root.

Gentian-root is a pure and excellent bitter tonic, useful in all cases of debility, whether of the stomach only, or of

the system generally. It possesses facilities, from not being decomposed, of being administered along with many metallic salts. It yields its properties to water, particularly when warm, to alcohol, and to wine. The simple infusion, and not the compound, of the 'London Pharmacopœia' should be employed, when any salts of iron are prescribed in the same formula. The extract is an eligible means of giving bulk, when several antispasmodic remedies, of which the dose is minute, are to be made into pills, such as oxide of zinc, protosulphate of iron, or extract of aconite. In the West Indies a preparation of gentian is used daily before meals, to give tone to the languid stomach.

In the East Indies several species are used as bitter tonics. The Chirayita, or Chiretta, in the form of a cold infusion, is much prized for its tonic and febrifugal virtues. Guibourt contends that this plant is the Calamus aromaticus of the antients, an opinion from which Dr. Royle dissents. ('Flora of the Himalaya,' p. 277.)

GENTIANA'CEÆ, an extensive order of monopetalous Exogens, consisting of herbaceous plants, with opposite ribbed leaves, and flowers whose corolla is imbricated, the stamens alternate with the petals, the ovary superior, with two cells standing right and left of the axis of growth, and seeds containing a minute embryo lying in a mass of albumen. They are generally considered to be in the closest alliance with Scrophulariaceæ, but it is possible that their resemblance to that order is one of analogy rather than affinity. Along with Orobanchaceæ and Monotropaceæ, they seem rather to belong to the albuminous group of Exogens, as has already been shown. [EXOGENS.] The flowers of these plants are usually coloured with pure bright yellow, red, or blue, and in many cases they are on this account among the most beautiful of flowers; but if we have a high development of form and colour in the majority of the species of this order, so we also have in the Guayana and Mexican plants belonging to the genus Voyra or Leiphaimos, the brown leafless habit and low development of Orobanche. This order is famous for its bitterness, which seems to pervade all the species. Gentiana itself furnishes all the officinal kinds; but Erythræa Centaurium, a beautiful wild flower, common in many parts of England, is advantageously employed by country-people as a substitute;

2 3 1

Gentiana lutea.

1, a capsule; 2, the same cut across, to show the placentæ; 3, a vertical section of a magnified seed.

and the root of Frazera Walteri has been used as a means of adulterating the bitter Calumba root.

GENTLEMAN, a corruption of *gentilhomme*, our Saxon ancestors having very early substituted 'mon,' or 'man,' for the corresponding term of the Norman-French, from which they originally received the term. Some form of this word (a compound of *gentilis* and *homo*) is found in all the Romance languages (*gentil-homme* in French, *gentil-uomo* in Italian, and *gentil-hombre* in Spanish), and it is undoubtedly one of the many traces of the great influence which the laws and polity of Rome have exercised upon modern society and civilization.

In the earliest form of the Roman constitution the populus, or ruling portion of the community, was divided into gentes, who were united by a common name, and the performance of certain sacred rights. Each gens was again subdivided into several familiæ, distinguished by a surname in addition to the common gentile appellation. Thus the gens Cornelia comprised the families of the Scipiones, the Lentuli, the Syllæ, &c. Now, in default of the Agnati, or of heirs in the male line, the property of the family reverted, not to the whole populus, in whom, of strict right, the sovereignty lay, but to the gens to whom it had transferred its rights.

This right of reversionary succession, especially in the case of usufructuary possessions of the public lands, being the most valuable and important privilege of the patricians, was brought prominently forward in the quarrels between the nobles and the plebeians, and the phrase *gentem habere* (Livy, x. 8) is often employed as distinctive of the former. Afterwards, when the members of the plebs obtained the right of intermarriage with patrician families, and an access to the honours of the state, which conferred the *jus imaginum*, or nobility, they also received the rights and privilege of *gentes*. To be admitted into a *gens*, became henceforward equivalent to a patent of nobility in modern times, and *gentilis* is accordingly widely defined by Cicero (*Top.* 6), as denoting those who were of the same name and stock, free-born, in the full enjoyment of all the rights of citizenship, and whose ancestors were always free. Hence also, in an opposite sense, '*sine gente*' is employed by Horace (*Sat.* ii. v. 15) and Suetonius (*Tib.* 1) for ignobly born and of servile parentage.

This privilege of succession, which was called *jus gentilitatis*, or simply *gentilitas* (Cic., *De Oratore*, i. 38), and formed one of the enactments of the Twelve Tables, was gradually undermined by the encroachments of the prætors on the civil law, and finally disappeared (Gaius, iii. 25); but the name has survived in all the languages of Western Europe.

According to Selden (*Titles of Honour*, p. 852), 'a gentleman is one that either, from the blood of his ancestors, or the favour of his soveraigne, or of those that have the vertue of soveraigntie in them, or from his own vertue, employment, or otherwise, according to the customes of honour in his countrie, is ennobled, made gentile, or so raised to an eminencie above the multitude, that by those lawes and customes he be truly nobilis, or noble, whether he have any title, or not, fixed besides on him.' That the word was formerly employed in this extensive signification is clear, from a patent of Richard II., by which one John de Kingston is received into the estate of a gentleman and created an esquire ('Nous lui avons resceivez en l'estate de gentilhome et lui fait esquier); and from another of Henry VI., who there, by the term 'nobilitamus,' creates one Bernard Angevin, a Bourdelois, a gentleman. And, according to Smith (*De Rep. Ang.*, lib. i. c. 20, 21), under the denomination of gentleman are comprised all above yeomen, whereby noblemen are truly called gentlemen.

In a narrower sense a gentleman is generally defined to be 'one who, without any title, bears a coat of arms, or whose ancestors have been freemen; and by the coat that a gentleman giveth, he is known to be, or not, descended from those of his name that lived many hundred years since.' (Jacobs' *Law Dictionary*.) There is also said to be a gentleman by office and in reputation, as well as those that are born such (2 *Inst.* 668); and according to Blackstone, quoting Sir Thomas Smith (1 *Comm.*, p. 406), 'Whosoever studieth the laws of the realm, who studieth in the universities, who professeth the liberal sciences, and (to be short) who can live idly and without manual labour, and well bear the port, charge and countenance of a gentleman, he shall be called master, and taken for a gentleman.'

The learned author must have been somewhat puzzled with his definition of a gentleman, as understood in his time. Having defined a gentleman to be one who studieth the laws, &c., he adds (to be short), that he who can live idly and bear the port, &c. of a gentleman, is a gentleman; that is, if he can live idly, and if he can also do as a gentleman does (it not being said what this is), he is a gentleman. Perhaps a definition of the term, as now used, would not be easily made; it being extended by the courtesy of modern manners to many who do not come within the antient acceptation of the term, and denied by public opinion to many whose rank and wealth do not make up for the want of other qualifications.

GENTOOS. [HINDUSTAN.]

GENUS, in physics, signifies a multitude or class of objects possessing some common quality or qualities: in logic it denotes the material part of the definition.

When we direct our attention to a particular object, we discover under its apparent unity a great variety of characters and qualities; and, upon an examination of several objects, we observe many points of agreement and difference between them. By the power which we possess of concentrating our faculties, we are enabled to consider these mutual relations and resemblances without any regard to their differences: we as it were draw the one away from the other; in short, we abstract them.

Now by abstraction we may either confine our view to a quality inherent in some object independently of that object; or else, neglecting the many points of disagreement which exist between a number of objects, we may seize upon the qualities that belong to all in common, in order to combine them into a single idea. In the former case the notion is simply abstract; in the latter it is abstract and general: and the multitude of objects to which we apply the general notion or common term constitutes a *genus*.

In this operation we may proceed continually by neglecting in succession a greater number of differences, and comprising under the common denomination fewer points of agreement and resemblance. In this manner we form a series of notions or genera of higher and lower order, until we ultimately arrive at the highest possible—that of *being*. In this co-ordination of genera, every intermediate genus is called a subaltern genus or species, being such in respect of different other terms; for that of which a higher genus is predicated is called a species, while relatively to all lower species it is itself a genus. Lastly, that which is not contained under any higher, is called the *summum genus*, and that under which individuals only are comprised is usually called the *infima species*.

These general notions and genera are the principles of classification and arrangement, and without them the knowledge of facts and nature itself would be, if not absolutely impossible, at best a confused mass of conceptions and objects without beauty, order, or coherence. But at the same time that we thus admit the utility of such general notions, we must remember that they are purely relative to human science and its objects; that even as such they are imperfect, and very far from conveying an adequate expression of the truth of nature, wherein there is nothing really corresponding to them, but only a something in the individual objects from which we derive them, which not only is the cause and the occasion of our forming them, but also transferring to them, as it were, a part of its own verity and existence, justifies us in according to them our confidence in science and action.

GEOBDELLA. (Zoology.) [LEECH.]

GEOCENTRIC (having the earth as centre), a term applied to the place of a planet, as seen from the centre of the earth, in opposition to its *heliocentric* place, as seen from the centre of the sun. [PARALLAX.]

GEOCICHLA, a genus of birds established by Mr. Gould for a pretty species resembling the Redbreast (*Erithacus Rubecula*, Swainson). It belongs, he observes, to an interesting group which was first characterized by M. Kuhl, and of which the Society's collection possesses four well-marked species. (*Zool. Proc.* 1836.)

GEOCOCHLIDES, Latreille's name for the shell-snails: *Trachélipodes colimacés* of Lamarck; *Limacinés* of De Blainville; *Limaçons* of De Férussac.

GEO'DESY is that branch of applied mathematics which determines the figures and areas of large portions of the earth's surface, the general figure of the earth, and the variations of the intensity of gravity in different regions, by means of direct observation and measurement.

Some of the antient philosophers, who lived several centuries before the Christian æra, were acquainted with the nearly spherical form of the globe, and even devised methods for measuring approximately a meridional circumference [ERATOSTHENES]. The Arabs long afterwards pursued the same object, and the Caliph Almamoun, in A.D. 814, ordered the measurement of a degree in the plains of Mesopotamia, an example which, after another long interval, was imitated by Snellius in Holland, Norwood in England, and by several French and Spanish mathematicians. Richer observed a variation in the length of the seconds' pendulum when sent to Cayenne by the French academy of sciences, the true cause of which phænomenon was explained by Newton; for the centrifugal force arising from the earth's rotation round its axis in twenty-four hours is directly opposed to the force of gravity at the equator, and in other latitudes the part of this force which acts in the direction of the plumb-line is nearly proportional to the square of the cosine of the latitude. He has also proved in his 'Principia' that a uniform fluid spheroid, in which the ratio of the centrifugal force to the attraction at the surface was the same as in the earth, would be in equilibrium when the axis of revolution was less than the equatorial diameter by 1-230th of the latter. From that time measurements have been undertaken under the directions of the various governments of Europe, to determine if the globe were really flattened at the poles, and also for the purpose of forming exact maps with respect to the latitude, longitude, and altitude above the level of the sea, of places in their respective dominions; and lastly, the French have deduced their legal metre of length from the measurement of a particular meridian arc. Jacobi has lately shown that a revolving fluid ellipsoid, having three unequal axes, may also present a surface of equilibrium.

The result of so many geodetic enterprises has not been as successful as could be wished. Some of the earliest attempts by the French were faulty in computation, and gave results directly contrary to Newton's theory, and some able mathematicians of that day appear to have been misled by a feeling akin to envy, to the extent of supporting these false conclusions by plausible reasonings. The error of that survey has been since discovered, and all the methods which have been employed in the numerous trials undertaken in this and the last century agree in proving that the polar axis of the earth is shorter than the equatorial by about 1-300th; but they have served at the same time to demonstrate that the earth is not a spheroid, that it is not a solid of revolution, and that the figures of the northern and southern hemispheres are dissimilar. Hence if we suppose a solid of revolution having its axis in the same direction as that of the earth, and osculating the surface of the latter, the excentricity of this spheroid varies both with the latitude and the longitude of the place.

If the materials which compose the solid mass of the earth had equal capacities for heat and became liquid at equal temperatures, the spheroid of revolution would most probably be the figure assumed at the epoch when the cooling of the whole had rendered it solid. Such however is not the case; a great portion of the surface of the globe is yet liquid, and of the solid parts some must have assumed that state prior to others. It is also possible that the temperature of space is variable within the extent of the solar system, and therefore the conditions for the cooling of the northern and southern hemispheres may be different, and a very small difference would suffice to produce, in a long series of ages, a marked difference between the temperatures of the two hemispheres, and therefore a corresponding difference would arise relative to their forms. The general sphericity of the earth cannot be otherwise conceived than by its primitive fluidity, and the irregular cooling of its parts accounts sufficiently for the observed departures from the spheroidical shape, which would have been otherwise produced by the attraction of its parts and the centrifugal force of rotation. The other bodies of the solar system which have short periods of rotation present the analogous appearance of unequal axes, the equatorial axis being always the longer.

In the trigonometrical survey of portions of the earth's surface, the extent or area may be computed more and more approximately by the suppositions of such portions being plane, spherical, spheroidical, and lastly of being

coincident with the osculating spheroid. We shall now explain the manner in which geodetic measurements are conducted, and the various corrections and reductions which it is necessary to apply to the principal calculations.

In order to measure an arc of the meridian, a series of stations are chosen near it in the most advantageous positions which the locality will permit; the lines which successively connect those stations form a series of triangles, in each of which, if one side and two angles, or two sides and one angle, are known, the remaining sides and angles are determinable by trigonometry; and if one extended line connected with the triangles, and called a base of verification, be measured, it serves at the different stages of the operation to detect any small errors which may have crept into the calculations. The stations should be so chosen that the triangles should be as nearly equilateral as possible, for then the errors of observation in the angles have the least influence in producing corresponding errors in the sides opposed to them. The measurement of the angles is effected by a theodolite, to which one or more telescopes are attached, with circles or arcs accurately graduated and accompanied by a vernier. The French, in the great survey between Dunkerque and Barcelona, which was conducted by Delambre and Mechain, employed Borda's repeating circle; while, in the English and Irish survey, a zenith sector, constructed by Ramsden expressly for this purpose, was used. It is of great importance that the telescopes should have a motion in azimuth as well as a vertical motion. In a Memoir on the Doctrine of Chances applied to geodetic operations ('Connaissance des Tems,' 1820, p. 422), Laplace shows that it is in general an advantage to have the series composed of as few triangles as possible, and yet in the surveys we have mentioned a great number were employed without producing on an extended base any considerable error. When a country is deficient in spires, towers, or other lofty edifices, situated conveniently for stations, artificial ones are easily raised, and if illuminated at the top and provided with parabolic reflectors directed towards the observer, these, when employed by night, are found eminently successful. Care must however be taken that this station be estimated at the foot of the vertical passing through the object observed, and corrections must be applied for any eccentricity in the position of the telescope, or error in its line of collimation. The angles observed not being in the horizon, must be reduced to it by a formula given in most treatises on spherical trigonometry. (Woodhouse's *Trigon.*, Appendix.) M. Delambre again reduced the latter angles to the angles between the chords of the spherical area between the stations, and therefore his series corresponded to the edges and faces of an inscribed polyhedron. (*Base du Système Métrique.*)

The three angles of any triangle in the series when added together are always greater than two right angles, which is a known property of every spherical triangle; but M. Legendre has shown that they may be treated as plane triangles by taking from each angle the third part of the excess of the sum above two right angles—a theorem of great use in geodesy, and which, as the same mathematician has proved, may be extended to spheroidical or other triangular portions of curved surfaces.

It happens not unfrequently that the instrument cannot be placed at the very centre of the station which forms the true angular point of the particular triangle in the series; by placing it as near to the centre as the observer conveniently can, a small correction, which is easily calculated, will reduce the observed angles to those which would have been observed had the centre been the point of observation: this correction is called *the reduction to the centre*. (Delambre, *Déterm. d'un Arc du Mérid.*, p. 24.) A similar correction must be applied when the observed object is a tower with a polygonal base. Another source of error is the oblique illumination of the observed object, which it is most important to correct, many of the surveys of the last century being faulty by the observer either disregarding or being ignorant of the change of apparent position which is thus produced.

The actual measurement of the bases is one of the most delicate operation in geodesy, and requires the greatest precaution; it is best that they should be as long as possible and chosen on level ground, or at least that they may be in vertical planes, so as to correspond to arcs of a great circle when the earth is regarded as spherical. But the great difficulty is to determine their lengths in reference to a fixed unit of length; for whatever material may be employed for the chain or rod of measurement, the variations of temperature will produce sensible alterations in their length. These indications must be reduced to a fixed state of the thermometer, and if they are of a nature to be affected by moisture, it will be necessary also to make a correction for the hygrometric state of the atmosphere. The French employed for rods a species of metallic thermometer consisting of a copper rod placed on one of platinum, which had precisely the same length at a known temperature; as these metals expanded unequally by heat, the difference easily indicated the proper correction: the English in the late survey first employed glass at Hounslow-heath, and afterwards also steel rods, and applied the correction for temperature, which was small in the former case. The following table gives the proper corrections for the materials generally used; it must be however remembered that the linear dilatation is not always the same in the three dimensions of a body:—

Names of Substances.	Linear Dilatation.	
Copper	·00001,72244	For one degree of Cent. therm.
Brass	·00001,86671	
Soft iron, wrought .	·00001,22045	
Glass tube, without lead	·00000,87572	
Platina	·00000,85655	

Sometimes it is impracticable to have a base coincident with a single geodetic line, as was the case in the instances of the bases at Melun and Perpignan; when accurately measured they are to be projected on a horizontal plane by multiplying them by the cosine of their inclination to the horizon, which being a very small angle, it suffices to subtract a small quantity proportional to the square of this angle.

$$(\text{Cos. } \theta = 1 - \frac{\theta^2}{2} \text{ when } \theta \text{ is small.})$$

General Roy in 1784 measured a base of five miles on Hounslow-heath, reducing his observations to the level of the sea and a temperature of 62° Fahrenheit, and formed a series of triangles between Greenwich and Dover. After his death (1790), Colonel Mudge extended it to Dunnose in the Isle of Wight: a verification-base being measured on Salisbury Plain; and the same great survey has been extended to Ireland and Scotland under Lieutenant-Colonel Colby, by whom a base of seven miles was measured near Londonderry.

The irregular figure of the earth is the cause that the geodetic meridian is not a plane curve. If through a point on the earth's surface and the axis of the earth a plane be drawn, this plane intersects the celestial sphere in a great circle, which is the celestial meridian of the place. Conceive verticals to be drawn parallel to this plane; the points where these verticals meet the irregular surface of the earth have evidently a common celestial meridian, and since the radius of this circle is indefinitely great, the locus of all these points forms a *geodetic line*. If another section of the surface be taken perpendicular to this, the radii of curvature of these two curves at their common intersection are sufficient to give that of any other section made through the same point by a plane of known inclination to either, whatever be the figure of the earth's surface, and the sum of the curvatures of any two rectangular sections through the same point is constant. The geodetic line possesses the singular property of being the shortest route between any two points taken in it; the equations to this curve of double curvature may therefore be found either by the differential calculus, if we consider the points of which it is the locus, or by the calculus of variations, if we regard the above-mentioned property. When the surface is one of revolution, this line is in the plane of the celestial meridian of the place, and is the same as the curve of revolution; but as it is not a plane curve, it follows that the earth is not a solid of this nature.

The refraction of light by the atmosphere is very great when the visual ray is nearly horizontal; and hence arise great errors in the measurement of angles, whether the observed objects are in the same level or not. These errors are generally remedied by an empirical law for terrestrial refraction, but all such laws fail to apply in the varied states of rarefection or of moisture in which the lower strata of the atmosphere are found; the best remedy is to seize the most propitious opportunities, when the heat of the surface of the earth has undergone no sudden changes, and when the atmosphere is fair and free from fogs.

All the preceding corrections being made so as to ensure the accuracy of the observations, it is necessary to reduce all to one level: for this level the mean surface of the sea, between its ebb and tide, or that which would be its level if there were no tide, is selected. The barometer must then be used to determine the altitude of the place of observation above this level, and a formula given by Laplace, and inserted in most treatises on hydrostatics, being applied, will give the altitude of the place, which with its latitude and longitude are all the co-ordinates necessary to determine its position. The preceding remarks are probably sufficient to give an idea of all the difficulties and delicate processes necessary for an exact trigonometrical survey.

The results of the most careful geodetic measurements show that the earth is compressed at the poles and extended at the equator. The lengths of a degree diminish regularly in the following different countries, to which we have annexed the names of the surveyors: Sweden, Melanderhielm; England, Mudge; Cape of Good Hope, Lacaille; France, Delambre; Italy, Boscovich; Pennsylvania, Mason; Peru, Bouguer; India, Lambton: but in distances which are small compared with the surface of the earth, the alteration in the length of the degrees is very irregular, as is strikingly manifested by the English base of General Roy, connected with the French of Delambre prolonged by Biot and Arago.

Another method has been adopted to determine the ellipticity of the earth by means of a seconds' pendulum, which, as well as direct measurement, indicates the flattening of the earth towards the poles. The following table is taken from the 'Mécanique Céleste,' tom. ii. No. 42; the latitudes are expressed in grades, and the length of the pendulum at Paris is adopted as the unit; the seconds are centesimal and of mean time:—

Place of Observation.	Latitude.	Length of Pendulum.	Name of Observator.
Equator	0·00	0·99669	Bouguer.
Porto Bello	10·61	0·99689	Id.
Pondichéry	13·25	0·99710	Le Gentil.
Jamaica	20·00	0·99745	Campbell.
Cape of Good Hope	37·69	0·99877	La Caille.
Toulouse	48·44	0·99950	Darquier.
Vienna	53·57	0·99987	Liesganig.
Paris	54·26	1·00000	Bouguer.
Gotha	56·63	1·00006	Zach.
London	57·22	1·00018	. . .
Arengsberg	64·72	1·00074	Grisschow.
Petersburg	66·60	1·00101	Mallet.
Lapland	74·22	1·00137	Academicians.

By employing the method of least squares, and assuming the figure of the earth to be nearly spheroidical, Mathieu has deduced from these observations $\frac{1}{315}$ as the fraction which expresses the eccentricity; the theory of the lunar inequalities make it to be $\frac{1}{\ }$, which differs but little from the former, and still less from that which corresponds to the southern hemisphere; the English observations would give $\frac{1}{290}$.

In the 'Philosophical Transactions' from the year 1819 to 1830, may be found the experiments on the length of the pendulum by Captains Kater, Sabine, Foster, and Mr. Fallows; an account of which, together with those of Freycinet and Duperrey, is inserted in the 7th volume of the 'Memoirs of the Royal Astronomical Society,' by Mr. Baily. Besides the works already quoted, the reader may consult with advantage the article on the Figure of the Earth, by Mr. Airy, in the 'Encyclopædia Metropolitana,' and the 'Traité de Geodésie,' by Puissant.

GEOEMY'DA. [TORTOISES.]

GEOFFRÆA INERMIS, or **ANDI'RA INERMIS**, is a tree inhabiting the tropical parts of America, and yielding a bark, with emetic, drastic, purgative, and narcotic properties, and in large doses poisonous. It acts as a powerful anthelmintic. The leaves are pinnate, and covered with a rusty down; the leaflets are oblong-lanceolate, or ovate-lanceolate, acuminate, and the flowers are arranged in terminal and axillary ferruginous panicles, very showy, with reddish lilac petals. Legume the size of a large plum. An account of it by Dr. Wright will be found in the *Philosophical Transactions* for 1777, p. 512, t. 70.

GEOFFREY OF MONMOUTH, otherwise named **ARTHUR**, the well-known British historian, was born in the town from which he took his name, and is supposed to have received his education at the Benedictine monastery in its vicinity. Tradition still points out a small apartment in the remains of that monastery which is designated as his study. He was made archdeacon of Monmouth, and on the 24th February, 1152, consecrated bishop of St. Asaph. Robert, earl of Gloucester, natural son of Henry I., and Alexander, bishop of Lincoln, were his chief patrons.

Walter Mapes, at that time archdeacon of Oxford, a diligent inquirer for his day after the works of antient authors, is said, whilst journeying in Armorica, to have met with a history of Britain written in the British tongue, the translation of which, upon his return to England, he recommended to Geoffrey of Monmouth, who undertook the task and completed it with great fidelity. At first he divided it into four, but afterwards into eight books, to which he added the book of Merlin's 'Prophecies,' which he had also translated from British verse into Latin prose. Numerous fabulous and trifling stories are inserted in the history, to an extent which has induced some authors, and among them Buchanan, to consider the whole as fiction; but others, among whom are Archbishop Usher, Leland, &c., consider that parts of his history are true, and that the work is not to be rejected in the gross. The best Welsh critics seem to consider that Geoffrey's work was a vitiated translation of the 'History of the British Kings,' written by Tyssilio or St. Talian, bishop of St. Asaph, who lived in the seventh century. Geoffrey's omissions, additions, and interpolations are very numerous; and his Latin for British appellations frequently very difficult to understand.

Several editions of Geoffrey's history are extant in Latin; the earliest is in 4to., printed by Ascensius at Paris in 1508; reprinted, 4to., 1517. It was also printed by Commeline at Heidelberg, in folio, 1587, among the 'Rerum Britannicarum Scriptores vetustiores et præcipui.' A translation of it into English, by Aaron Thompson, of Queen's College, Oxford, was published in London, 1718, in 8vo. (Tanner, *Bibl. Britan. Hib.*, pp. 305, 306; Nicholson's *Hist. Library*; Chalmers's *Biog. Dict.*, vol. xviii., p. 488-492.)

Copies of Geoffrey of Monmouth's history, in manuscript, are not unfrequent in our great libraries: several, of an age very near his time, are preserved among the manuscripts of the Old Royal Library in the British Museum; one formerly belonging to the library of Margan Abbey is believed to be the best. Geoffrey of Monmouth died about the year 1154.

GEOGRAPHY (a term derived from the Greek *γεωγραφία, geographia*) is a science the general object of which is to describe the surface of our globe. Its more special object is to ascertain and describe such physical peculiarities in each country as tend to promote or retard the increase of population and the arts of civilized life.

The political condition of a nation and the changes to which it is subject are in a great degree dependent on the character of the country which it inhabits, or of those countries which surround it. The difference in civilization observed in nations living near one another may also in a great degree be ascribed to the same cause. Accordingly we find that as soon as men began to apply themselves to the explanation of such changes and differences, they were obliged to look to the particular character of the countries inhabited by those nations whose history it was their object to investigate. Geography is coeval with history. It is as impossible to form a just idea of the events which have been most decisive in the history of a nation without a knowledge of their country, as it is to understand the movements of two armies on a field of battle without knowing the nature of the ground which is the scene of their operations.

Herodotus, the father of history, is likewise the father of geography. His geographical descriptions are short and general, but always clear and sufficient to show how far the physical peculiarities of each country influenced the changes and events which he had undertaken to commemorate. When he found that a country was characterized by striking peculiarities he described them at considerable length. An instance of this is his description of Egypt in the second, and his description of the Scythians and their country in the fourth book.

There is however something vague in the descriptions of Herodotus, for want of a means of referring to the position of places as determined by astronomical observations. Herodotus indeed was apparently not fully acquainted with the state of science, and particularly astronomical knowledge, as it existed in his age. Thales had some time before calculated an eclipse of the sun, and from his epoch astronomy attracted the attention of the Greek philosophers, and facts

in this science began to accumulate. It was however soon evident that most of these facts lost a great part of their value, from the circumstance of the position of places not being ascertained. Astronomers therefore were led to devise a method of fixing the latitude and longitude of a place; and though this method, when compared with our practice, was extremely rude and imperfect, yet it must be considered as having materially contributed to the improvement of geography. With the help of such astronomical observations as were made by his predecessors or himself, Eratosthenes formed the first system of geography founded on a basis which in some degree approached to truth. He determined the geographical position of a great number of places, many of them hardly known to Europeans, but these determinations were often founded on vague information, and consequently were in a great degree conjectural. Still his map gave a much truer image of the figure of the world than philosophers had formed before him, as he took care to subject his information to a strict examination.

While his successors were slowly improving his work, the historians, following up the plan traced by Herodotus, enriched geography with the description of those countries which at the time of the historian of Halicarnassus were not known, or at least only imperfectly known in Greece. Among these historians Polybius deserves particular mention. His geographical descriptions of the countries which enclose the western portion of the Mediterranean Sea are as good as, if not superior to, those by Herodotus of the countries between the Caspian Sea and the Gulfs of Persia and Arabia. About his time, or shortly afterwards, it would seem that several persons undertook travels into remote countries, in order to investigate their physical character and to ascertain the accuracy of such information as had reached them by hearsay. The most conspicuous among these adventurers was Posidonius. Like Alexander von Humboldt he went to the then remotest country of the earth, to Iberia, which was as noted for its mines of the precious metals as South America and Mexico are in in our times; and though only a small portion of the information which he collected is come down to us, he seems to have paid great attention to nearly all the objects of inquiry which the German philosopher has investigated.

The geographical information collected by these eminent travellers and many others of less note was scattered over a great number of works, access to which, in the circumstances of those times, was necessarily difficult. Strabo, a native of Asia Minor, who wrote in the time of Augustus and Tiberius, undertook to incorporate in one work those scattered materials and to add the information which he had acquired in his own travels. His object, according to his declaration, was to compose a work which should be useful to those employed in the administration of countries. He accordingly discarded everything which was only of temporary importance, and described each country according to its permanent physical character. In a few words he informs his reader of the extent of each country under description, and its chief political and historical divisions. Passing on to the detailed description of these divisions, he follows much more nearly the course of our modern travellers than that of our geographers. Mountains, plains, valleys, rivers, and towns keep their true position with respect to one another; productions and climate are mentioned in their proper place. A few short observations on commerce and the articles of export conclude his description. By this judicious arrangement the sagacious Greek geographer avoided causing to his readers that weariness which every one experiences in perusing common geographical books, in which every object is as it were rooted out from its natural place and transported to a foreign spot. We cannot help thinking that the method of treating geography adopted by Strabo ought still to be considered as a model, and ought to be again introduced into works of this class; and we find that Charles Ritter, in his justly esteemed geographical works, strictly adheres to the plan of Strabo.

Whilst the geography of Strabo was extensively used all over the Roman world, the astronomical school of Alexandria continued collecting materials for the purpose of completing and perfecting the system of geography framed by Erastosthenes. These collections enabled Ptolemy to form his geography, which is hardly anything else but a catalogue of places according to their estimated or determined geographical position. In its time it was certainly a very useful work, but its value to us consists chiefly in showing how far the Greeks had carried their knowledge of the surface of the globe. From the time of Ptolemy up to the fourteenth century scarcely anything was added to what he left behind him.

The downfal of the Roman Empire, and the occupation of Western Europe by barbarous nations who were hardly acquainted with the elements of civilized life, suddenly extinguished all scientific research. Many centuries elapsed before these nations made such progress in civilization as to enable them to turn their attention to science. Geography, which shared the fate of the other sciences, was however revived sooner than the rest, and the circumstance which led to this was the travels of the Venetian, Marco Polo. Though his accounts were rejected by his countrymen as mere fictions, or at any rate were treated as great exaggerations, some German scholars at Nürnberg took a different view of them. As Nürnberg at that time was one of the greatest trading places on the Continent, and for that reason closely connected with the first commercial houses of Venice, these learned men soon procured a copy of Marco Polo's travels. For the other countries of the world taking Ptolemy as their basis, they introduced the principal geographical facts contained in Polo's travels into their globes and maps, as an addition to the knowledge transmitted by the astronomers of Alexandria. But Marco Polo had made no astronomical observations, nor had he even mentioned the length of the longest day at any place. The German geographers were therefore obliged to determine the extent of the countries which he had traversed by his vague estimates of days' journeys; but the length of these journeys was greatly exaggerated by them, as they were entirely unacquainted with the peculiar character of Eastern Asia. The consequence of this was, that on their maps and globes Asia extended over the whole of the Pacific, and its eastern shores were placed very nearly where the Antilles are situated. This error of the geographical school of Nürnberg was attended with very important consequences. Columbus, relying on their estimates, considered that the shortest way to arrive at the eastern parts of Asia would be by sailing to the west. He found America: but the same school of geographers whose errors had induced him to venture on such a voyage deprived him also partly of the honour due to his great discovery. Baron von Humboldt has proved that the very slow and insecure communications which then existed between Spain and Germany brought the news of the discovery of the New World to the geographers of Germany together with the names of Columbus and Americo Vespucci, and that the Germans thought that Americo was the true discoverer of the new continent, which accordingly obtained from them the name of America, a name that has become universal.

The first half of the sixteenth century was entirely employed in discovering the extensive coasts of America, and the countries and islands lying along it, and in the Indian Ocean; and geographers were fully employed in inserting these new discoveries in their maps according to such determinations of positions as they could obtain. In all the geographical works written during that century this characteristic is observable. They resemble much more the geography of Ptolemy than that of Strabo. But what could geographers then know of the interior of countries whose very coasts were yet hardly laid down with accuracy even in a few places?

In the mean time the other sciences had been revived and with them also the study of antiquity, which gave a different turn to the study of geography during the seventeenth century. Many persons well informed in antient history visited Greece and the countries of Western Asia, with the view of examining those parts which had once been the theatre of great events. Such *historical* travellers were very numerous during the second half of the seventeenth and the first half of the eighteenth century; and though at first they confined their researches chiefly to such places as had obtained some historical celebrity, they afterwards extended their views to the physical character of the countries in which such places were situated, and gave us some excellent descriptions of them, such as we find in the travels of Chardin, Shaw, Pococke, Chandler, and Carsten Niebuhr. These travels greatly contributed to the improvement of geography as a science. They brought history and geography again into close connection. Before this time geographical works contained hardly any thing beyond a dry catalogue of names of places, rivers, and political divisions. But in describing the

still existing ruins of places celebrated in ancient history, geographers were compelled to go back to those antient authors who had treated of these places, and thus a part at least of the geographical knowledge of Herodotus, Polybius, and Strabo, was transplantod into our modern geographical treatises. Thus a great deal of very interesting and useful matter found its way into treatises on geography, which had hitherto been entirely excluded, partly because it had not been known, and partly because it had been considered as foreign to the object of the science. If any person will take the trouble to examine any of the geographical works of the middle of the seventeenth and eighteenth centuries, he will find that more than three parts out of four of their contents have changed in the course of 100 years.

Still the science of geography remained in a very imperfect state. Only a few spots in each country had been described with any degree of precision. The peculiar character of an entire country, and of its component parts, had never been made a subject of inquiry. It had never been a subject of investigation, how far the physical character of a country was favourable or adverse to the civilization of its inhabitants. This has now in a great degree been effected by the naturalists and other men of science, who during the last and the present century have visited nearly every part on the globe. In course of time the researches of travellers and voyagers have thus been extended to a greater number of new objects. At first they limited their labours to the extension of Natural History, adding a few observations on the countries through which they passed. Thus Tournefort, who travelled through Asia Minor, Armenia, and Persia, may be considered as the first travelling naturalist. But by examining the natural productions of a country travellers were insensibly led to an investigation of their climate. In their attempts to establish the mean temperature of different places, and its effects on vegetation and animal life, they soon perceived the great influence which a variation in elevation above the level of the sea has on both. Thus they gradually learned that nearly every country is divided by nature into a smaller or greater number of parts materially differing in climate and natural productions. The knowledge of this fact mainly contributed to give geography a new character, and to introduce new and important elements into the geographical descriptions of countries, such as we find in the works of Pallas, Sir Francis Hamilton, and Alexander von Humboldt. What these great men, and several of their less distinguished predecessors did for the countries out of Europe, has been accomplished with equal success for the European continent by the labours of numerous excellent writers.

Geography, then, in its present state, and in its practical application, has for its object the determination of all those facts, as to any given country, which will enable us to judge of its fitness to provide man with food and to promote his civilization. As a science, its object is to deduce, from all the observed phænomena within its sphere, those general principles which enable us from certain known facts, as to any given country, to infer others not ascertained, and which indicate what are, as to each portion of the earth, the proper objects of inquiry. It is not every part of a country that possesses equal advantages for the habitation of man. Some parts are more favoured by soil and climate than others. There are also tracts which are inferior in both respects, but by the aid of other advantages, especially those of easy communication, have risen to a higher degree of prosperity and cultivation than many others in their neighbourhood which are more favoured in soil and climate. No correct knowledge of a country can be acquired unless the parts of it which are distinguished by their natural advantages or disadvantages are separated from each other, and unless a particular description is given of each, with its extent, and the proportion which it bears to the whole country. The first business of the geographer then must be to make this separation. His next business is to give a particular description of each of these natural divisions, beginning with the most essential fact, its elevation above the sea. If it is a valley, he notices its elevation at its origin and its termination, observing where its descent is regular and gradual, and where it declines with greater rapidity. If it is a plain, he notices at least its mean elevation, and observes in what cases it extends in a flat level, and in what cases it has an undulating surface; also, if a smaller or larger portion of it is covered with swamps. This description of the surface is followed by that of the water-courses or drainage. After determining the sources of a stream, and the direction and length of its course, he mentions the amount of depression of its bed below the general surface of the valley or of the plain; and when it drains a plain, if there are bottoms or river-valleys formed on the surface of the plain, he mentions also the general extent of these bottoms. The distance to which a river is navigable is the next object of inquiry: if there are any natural impediments to the navigation, and if any successful attempts have been made to remove them, these facts also require mention. The extent of surface drained by each river, or by all the streams which ultimately unite in one channel; in other words, the extent of each river-basin must also be ascertained. Next follows the climate. Here two points especially are to be attended to; the temperature of the air, and the quantity of rain which falls, and of moisture in the atmosphere. As for the temperature of the air, not only the mean annual temperature is to be given or ascertained, but also that of the different seasons, and the regularity or irregularity of its changes, as such changes generally affect the health of the inhabitants in a sensible degree. As to moisture or rain, not only the annual quantity that falls should be noticed, but also its distribution at the different seasons. The character and the duration of the seasons must also be observed, and the prevalent winds; and especially the effect of the seasons on the progress of vegetation. It is necessary to know all these facts before a just notion can be formed of the fitness of any given tract of country for providing a population with food. And this capability of a country for the production of food, or in other words its capabilities for agricultural purposes, is one of the most useful branches of geographical inquiry. The nature of the soil and its fitness for different productions adapted to the climate of the tract, are therefore matters of primary importance in a geographical description. It is here proper to enumerate those objects of agriculture which are raised for food and as materials for clothing, and the proportion between the labour which they require and the value of the produce: and in the next place such productions as could be raised with ease and advantage, but which are not cultivated to any extent. Those objects which form articles of export, and enter into the market of the world, also claim a notice; and also such indigenous plants as are either of some use in the domestic economy of the inhabitants, or furnish a commodity for foreign trade. It is not the business of the geographer to enumerate all the particulars which constitute the botany or zoology of a district, for that would enlarge his science beyond all bounds and encroach upon the limits of others. The principle that must guide him in determining how much and what he must include in his geographical description of the botany and zoology of a country, will always be indicated by the question—does the thing or object inquired after materially influence the capability of the country as a place fitted for the residence of man? Besides the useful domestic animals, it is only necessary to mention such wild ones as are useful to the inhabitants, either by providing them with food and clothing, or by supplying an article of commerce; and these animals only need be mentioned when they are found in great numbers. As for the mineral wealth of a country, the notice of that will be limited to those substances which are worked for the use of the inhabitants or for exportation.

In this way we conceive the geographer ought to describe in detail each natural division of a country, and when he has described two such tracts which are contiguous to one another, he must point out the boundary-lines by which nature has separated them, and the obstacles which she has placed to their mutual intercourse. If he finds that such boundary-lines are formed by mountain-ranges, he has to notice their mean elevation, and likewise that of the mountain-passes by which the dividing range is crossed. He must also add what natural productions of the range contribute to the sustenance or comfort of the inhabitants of the adjacent tracts. When the range has numerous offsets and extensive valleys, and consequently occupies a considerable part of the country, he must treat it as a separate natural division, and describe it in detail like any other natural division.

When the geographer has described every natural division of a country in this way, and incorporated in his description the best attainable information on all the above-mentioned points, we think that he has done his duty, and ma,

consider his labour as terminated. But our geographical treatises still contain other matter, which is not comprehended within the above enumeration of objects belonging to the science of geography. This extraneous matter is taken either from statistics, or from what is popularly called natural philosophy or from history; and it ought to be considered how far it is expedient to admit such matters into geographical treatises.

As to statistical facts the greatest caution ought to be used. Most of them are of such a description that they are true only for a very short time, and then lose that character. Such things, according to the opinion of Strabo, ought not to be received among things which are of an entirely different nature. Yet the knowledge of a country would properly be considered as incomplete without a general notion of the most commercial and manufacturing towns within it. Such towns must therefore be mentioned, and at the same time it should be stated how far they facilitate the internal and external intercourse of a country. The political divisions of the country may be added or omitted; when added, they should be mentioned briefly, and in a very general way. Good maps supply any deficiency in geographical works in this respect.

We do not venture to exclude entirely from geographical works all mention of natural phænomena peculiar to a country. Some of these, as volcanoes and earthquakes, though they do not exercise a permanent influence on the welfare of the inhabitants, are frequently destructive of property or life, or of both. For that reason they ought to be noticed. Such phenomena as warm or mineral springs seem also to claim a notice, especially if distinguished by peculiar characters, as the Geysers in Iceland.

It is more difficult to determine how far it is proper to describe the remains of antiquity in geographical works. When the ruins of a great city still exhibit remarkable traces of its antient grandeur, they certainly cannot be altogether excluded. But the true solution of these and other difficulties of the kind that may be suggested as to the matter admissible into a geographical treatise, seems to be this: these subjects are *specialties*, and if they belong to geography at all, do not belong to it as necessary component parts of it, but stand to it in such a relation as to admit of being introduced or omitted according to the taste and judgment of the writer, who in this, as in all branches of knowledge whose boundaries are incapable of precise determination, will show his good sense and his clear comprehension of his subject as much by what he omits as by what he takes in.

The political institutions of a country belong to its history, and not to its geography, and ought certainly to be excluded from geographical treatises, though they form a necessary part of most statistical and of all historical works.

The importance which geography, as a science, has attained of late years, has suggested the formation of Geographical Societies. The main object of such societies is, or ought to be, to encourage the accumulation of facts as to countries that are little known. The first Geographical Society was established at Paris in 1821. The 'Transactions' of this society, in five volumes, in 4to., contain very little original information. They are chiefly valuable for the history of geographical knowledge: they contain complete translations of the travels of Marco Polo, and of the geographical works of Abulfeda and Edrisi. The third volume contains the 'Orographie de l'Europe,' which presents a tabular view of the elevation of numerous mountain summits and other positions: it is executed with considerable correctness, and is a very useful work. The second society of this kind was established at London, in 1830, and called the Royal Geographical Society. This society publishes annually a volume of Transactions, under the title of the 'Journal of the Royal Geographical Society.' We think it may be safely asserted that there has seldom appeared a work which, for amount of original information, can be compared with these Transactions. This country indeed has greater facilities for procuring geographical information than any other, and the society has not failed to make the most of these resources. The naval officers employed by Government and the East India Company in surveying various parts of the coasts of Asia, Africa, America, and the Mediterranean Sea, have made valuable contributions to the volumes of the society. The information contained in these communications is distinguished by a correctness proportionate to the attention which their professional duties required of them. Of this character particularly are the accounts of the coasts of South America, by Capt. Phillip Parker King and Capt. Fitzroy. Various persons who have been sent out by Government in a public capacity have added to the stock of useful information: as Lieut. (now Capt.) Washington, on the empire of Marocco; Mr. Brant, on Armenia and Asia Minor; Major Mitchel, on the interior of Australia; and others. Many travellers, who had no intention of publishing their observations in the shape of a book, have communicated them to the world through the 'London Geographical Journal;' and it is certain that most, if not all, the information contained in many of those valuable papers would have been lost to science but for the existence of the society. Though the annual contribution of each member is but small (2*l*.), by a judicious management of their funds and the aid of Government the society has been enabled to send out travellers to such of our foreign possessions as are yet imperfectly known. Thus Capt. Alexander was sent to the Cape of Good Hope, Mr. Schomburgk to British Guiana, and Capt. Back to the Arctic Regions, and other expeditions are in contemplation. The success of the British Society has led to the formation of a similar society at Berlin (1833), and at Frankfort-on-the-Main (1837), which however, up to the present time, have not published any Transactions. A Geographical Society has also been formed at Bombay, which has for its object 'the elucidation of the geography of Western India and the surrounding countries.' (*London Geograph. Journal*, vol. iii. 1833.)

GEOLOGY. § 1. Historical Notices of the Progress of Geological Science.—The science of the earth (as the Greek words γῆ and λόγος may be translated) includes, in a large sense, all acquired or possible knowledge of the natural phænomena on and within the globe; whether these be now of frequent occurrence, the result of the existing combinations of physical agencies, or remain as monuments and measures of those agencies in earlier periods of the history of the planet.

Some of these phænomena are witnessed in connexion with inorganic bodies, and depend in a great degree on the laws of force which appertain to and distinguish from each other the particles of matter; others are exemplified in organised structures endowed with vital functions related to those structures; and there may yet be distinguished a third order of effects, influencing and combining with both of the former, and depending on laws of force which affect the whole mass of the globe, as gravitation, or derived from extraneous agency, as light.

If at any certain epoch (as the present time) the phænomena thus classed were known in detail, and reduced to general laws, which truly expressed the individual cases, the actual condition of the earth would be really known: if further it were possible to collect sufficient evidence from monuments preserved in the earth of its exact state at some former epoch, the variations to which terrestrial phænomena are subject would be disclosed; and by the comparison of several such surveys, taken at distant times, the laws of these variations would be revealed, with an exactness proportioned to the certainty with which the *intervals of time* were determined. These laws of the *variation* of the condition of the globe at successive epochs, combined with the laws of chemical, vital, and mechanical action, which are assumed to be essential and constant, independent of time, and exempt from change, will furnish one, and only one, satisfactory general contemplation or theory of the origin, structure, and successive changes of the globe, considered as a part of the planetary system revolving round the sun.

To reach this general theory is the highest ambition of modern geology. The discovery of the right method of proceeding in this attempt is of modern date; and all the most important steps of the advance towards this 'high point of knowledge' have been taken within the memory of the generation now passing away. If, as Sir John Herschel tells us ('Discourse on the Study of Natural Philosophy,') 'geology, in the magnitude and sublimity of the objects of which it treats, undoubtedly ranks, in the scale of the sciences, next to astronomy,' it owes this great distinction to the humility with which its modern cultivators have sought within the ranks of inductive science better methods of research and purer models of reasoning than those afforded by the treasures of ancient philosophy which have

been preserved to our time. Nor is this the peculiar boast or shame of geology. Every branch of the study of nature was equally transformed by the introduction of the Baconian methods of interpretation of nature; all the natural sciences have advanced together; the knowledge of the constant laws in the visible creation has been continually perfected; and thus, while the study of the long-past operations of nature has been imbued with the exactness of chemical, zoological, botanical, and physical research, the dry annals of one æra in the history of the world have been enriched into a long, instructive, and eventful history.

Geology of the Greeks.—Among the antients the notices of geology are few, and the interest belonging to them is of a peculiar character. When chemistry, whose operations manifest the existence of peculiar laws of force among the particles of matter, was wholly unknown—when the living wonders of creation were but slightly considered by philosophers intent on abstract principles—no accurate survey could be taken of the condition of any one part of the surface of the earth. But a small part of that surface was known to any one people, and only in a few situations were the changes in the aspect of nature so extensive as to arrest the attention of the geographer, or so violent as to excite the philosopher to search for the cause.

Among the anciently-peopled and commercial states of the eastern shores and islands of the Mediterranean, both these circumstances concurred, and there first awakened the powerful intellect of Greece to speculation on the varying condition of the land and sea. Lower Egypt is the gift of the Nile, and the powerful and learned people which possessed it were compelled by the circumstances of their situation to study the nature and effects of the annual floods of the river. Herodotus (born 484 B.C.) estimates (ii. 11) that the Nile, if diverted into the Red Sea, would fill that long gulf in less than 20,000, or even 10,000 years. The notion of change thus distinctly impressed upon the minds of the Egyptian priests was developed in a general and philosophical form, and illustrated by special references to an extended series of geological phænomena by their pupil Pythagoras (born 586 B.C.). According to the summary of their doctrine, and the tenor of the illustrations of it which are given by Ovid, we cannot avoid seeing, even through the injurious ornament of verse, that Pythagoras had acquired a clear conception, a 'distinct idea,' of nature as existing by the concurrent action of many complicated powers, which were subject to continual or sudden variation in their relative intensity. Changes of the relative level of land and sea, and divulsion of islands from the mainland by the action of earthquakes, are distinctly announced; the displacement and limited duration of volcanic vents, such as Ætna; the degradation of land by the action of atmospheric agency ('et eluvie mons est deductus in æquor'); the submersion of land which had been formerly peopled—

> Si quæras Helicen et Burin, Achaidas urbes,
> Invenies sub aquis.—(Ovid, *Metam.* xv., l. 293.)

the production of new land, and the occurrence of marine shells far from the present seas;—these phænomena, distinctly observed and analyzed, and clearly produced in proof of a general proposition, justify a higher degree of admiration for the Samian philosopher than is due to any of the merely speculative writers of antiquity.

Similar observations appear to have served as the groundwork of Aristotle's exposition ('Meteorologica') of the perpetual fluctuation of natural phænomena; the alternate excitation and rest of parts of the earth's surface. (See particularly the end of the first book.) But it is in Strabo (nearly contemporary with the commencement of the Christian æra) that we find the most sensible views of the causes of the occurrence of marine shells far from the shore, the displacements of land and sea, the rising of islands, the formation of straits, and other great geological phænomena.

Having stated the views of Eratosthenes, as to the general fact of the earth's globular form, and the production of the numerous minor inequalities on its surface, by correspondingly numerous 'proximate causes,' such as the operations of water, heat, concussions, vapours, and the like, he examines the opinions of Xanthus and Straton, which Eratosthenes had preserved. (Strab., *Casaub.* 49, &c.)

The explanation of Xanthus (derived from an historical fact) that the phænomena in question were due to great droughts which had diminished the originally greater expanse of the sea, is regarded as insufficient; and Strabo's hypothesis of adjacent but disconnected seas, one of which being raised to a higher level by sediment on its bed, had forcibly opened itself a passage to the other, the Euxine to the Propontis, the Mediterranean to the Atlantic, is shown to contradict received physical theorems. Strabo proposes to account for these and other phænomena by the general speculation that the land, not the sea, is subject to changes of level, and that such changes more easily happen to the land below the sea, 'because of its humidity.'

The action of Ætna in moving the shores of Sicily and Italy is spoken of in a familiar manner, and a long description of phænomena bearing on the discussions succeeds, in which the opinions of many authors are quoted.

Fifteen hundred years elapsed after the æra of Strabo, without adding anything material to the stock of geological facts, or the limited range of rational theory; for, excepting the work of Omar (10th century), in which the phænomena of 'new lands,' and marine shells found inland, are referred to a 'retreat of the sea,' there is not, on the subject of geology among the Arabian writers, even the usual amount of comment on the writers of Greece and Rome which characterizes the literary efforts of the learned Moslems. (Lyell's *Principles of Geology*, vol. i.)

Revival of Geology in Europe. Nature of Organic Fossils.—Italy, the fruitful mother of modern physical science, offered in her volcanic cones, ranges of mountains, and shelly marls at their bases, the most attractive points to the intellectual activity of the precursors and contemporaries of Galileo.

So recent are sound views of the true nature and relations of the organic forms buried in the earth, that it is not very difficult for English geologists to imagine the fierceness of the contest in which Fracastoro (1517) was involved, to defend his opinions that the 'formed stones' (as they were afterwards termed in England) were not 'lusus naturæ' produced by a 'plastic force,' but really the remains of fishes, mollusca, &c.; and that they had not been rudely scattered over the surface by the Noachian flood, but buried at great depths by a more regular operation of water. These important assertions were the subject of controversy for nearly two centuries in Italy; and in establishing the true nature of the organic remains, Cardano, Colonna (1666), and Scilla (1670) overlooked or disregarded the more seriou and more seducing error of ascribing their inhumation in the earth to a general deluge. Georgius Agricola (1546) adopted the wrong view of the origin of organic fossils: but Steno (1669) of Copenhagen, opened a new line of inquiry, by noticing the succession of rocks; distinguishing some as having been formed before the creation of animals and plants; insisting on the original horizontal position of the strata; tl proof of violent movement of the crust of the globe, afforded by the now inclined position of such strata in mountainous countries; and the variations of condition to which the surface of Tuscany had been exposed, by repeated overflows and retirements of the sea. (Lyell, *Principles of Geology.*)

Scilla's masterly work on the organic remains of Calabria, published both in Latin and Italian ('La Vana Speculazione disingannata dal Senso,' 1670), may be considered as closing the long dispute in Italy, among men of philosophical minds, on the subject of the nature of organic fossils. Its was comparatively very short in England, for Plot (in 1677) is almost the only writer who really and heartily embraced the doctrine of an occult cause, to escape from the consequence of admitting the true origin of the 'formed stones,' and Scilla's work was abridged for the 'Philosophical Transactions' in 1695-6, by Dr. Wotton. Lister's early views on the matter (1678) express a doubt, arising from knowledge; he saw that the fossil shells were *different* from the living types, and proposed the alternative of a terrigenous origin, or an extinction of species. Ray (1692) on 'Chaos and Creation,' Woodward's 'Natural History' (1695), Scheuchger's 'Herbarium Diluvianum,' of the same date, afford proof of the victory gained by the observations of naturalists over the closet speculations of metaphysicians, on the origin of fossil shells in most parts of Europe; and indeed, in France, Palissy's lectures and writings (his last publication bears the date of 1580) may be said to have established the truth contended for.

Submersion and Desiccation of Land.—The victory was unproductive. In consequence of coupling with the obvious truth a fatal and fundamental error, the shells and other exuviæ of the sea were maintained by Woodward

and a host of contemporaries and followers to have been brought upon the land by the 'universal deluge,' as all writers except Quirini (1676) agreed to term the Noachian flood. This error might speedily have been swept away by the early arguments of Palissy, the investigations of Steno, and the striking generalization of Lister; but that, unhappily, from a philosophical question, it became a theological argument. The fossil shells far from the sea were held to be physical *proofs* of the truth of the Mosaic narrative; and the occurrence of these shells at various depths and heights, and in rocks of different kinds, only furnished additional arguments in favour of the violence of that flood, which not merely was supposed to have covered the mountains, but to have entirely broken up and dissolved the whole frame-work of the earth, and to have deposited the materials according to their relative gravity. In vain had Hooke, Ramazzini, and Ray, previous to 1700, protested against the absurdity of this hypothesis, which Leibnitz appears to have despised; it was reserved for Moro (1740), Buffon (1749), Linnæus (1770),* and Whitehurst (1792), to hasten its banishment from philosophy; and even at this day there are persons who from time to time revive the discussions of the sixteenth century, as a point of importance in Christian theology.

To account for the dryness and elevation of the countries where fossil shells occur, there are but two hypotheses: the shelly bed of the sea has been raised, or the ocean has abandoned its antient place. Many of the Italian geologists adopted the former view, and in consequence repeated the opinions and reasonings of Strabo, with the advantage of referring to the elevation of Monte Nuovo near Puzzuoli, in 1538 and Santorino, 1707 (Majoli, 1597; Vallisneri, 1721; Lazzaro Moro, 1740). The better order of English writers (Hooke in 1668, Ray in 1692—earthquakes were then frequent in Europe) adopted the same views; and Hooke in particular presented the phenomena of earthquakes and volcanoes in the form of a general speculation, which served to direct the opinions of subsequent systematists like Whitehurst.

Diluvial Hypothesis.—None of the philosophers who were concerned in establishing the truths connected with organic remains were seduced by their success into the vanity of proposing any general hypothesis on the formation of the earth. But this creditable modesty, so characteristic of the spirit of induction which animated Fracastoro, was not at all imitated by the fanciful diluvialists, who followed in the wake of Woodward, Burnet, Whiston, Catcott, and others. To determine whence came the water which held at once in suspension the whole of the exterior parts of the globe, and whither it retreated, was necessary to help out their extravagant proposition.

No ordinary hypothesis would meet these formidable problems, and if we recollect that in answering them it was further required to adopt views which should not trench on the arbitrary notions then entertained as to the meaning of certain passages of Scripture, we shall be disposed to regard even the monstrous violations of physical truth which appear in the hypotheses of Burnet, Woodward, and Whiston, without surprise. Omitting minor circumstances which it would be useless to particularize, Burnet, Woodward, and their followers agreed in adopting the notion of an interior abyss below the crust of the earth, as the general reservoir from whence the waters rushed to cover the earth, and into which they again withdrew after the diluvial devastation was completed. Whiston, who was far better versed in physical science than either of the others, introduced in addition the notion of extraneous force; he brought a comet to envelop the earth in its misty tail, to cause violent rains, raise vast tides in the internal abyss, and thus effectually destroy the external crust of the planet. It appears probable that mankind seldom permit their imaginations to take such dangerous flights without necessity; the hypothesis is made to suit the conditions of the moment, and the chief error consisted in including among these conditions a narrow and unreasonable interpretation of the Mosaic narrative. This error lies even yet at the root of some well-meaning speculations, which from time to time arise, a century after their proper date, for the avowed purpose of reconciling geological and scriptural truth.

* 'Ubi testacea et lithophyta fossilia existunt in magna copia, ibi quondam fuere littora aut abyssus, cum sint mera vestigia maris, omni historia antiquiora; diluvium vero non demonstrant, sed tantum longioris ævi rudera.' (*Syst. Nat.*, Foss. Petrif.)

General Speculations.—The diluvial hypothesis has been sufficiently traced to its natural consequence—a monstrous violation of the laws of nature; another general view, first distinctly stated by Vallisneri (1721), has been the source of long-continued errors. Struck by the general diffusion of marine fossils, he supposed the ocean to have once extended over all the earth, and to have gradually subsided, leaving everywhere the traces, not of a violent flood, but of the quiet super-fluctuation of water. Perhaps Vallisneri found this notion in his travels; at any rate, the notion of a universal subsidence of the ocean appears to be the German element of geological hypothesis, for Werner made it the basis of his so-called theory of the earth, and thus obscured with a physical improbability the important truths which he had established concerning the succession of strata.

Starting from an entirely different point, Leibnitz (in 1680) proposed one of the most general contemplations which has ever appeared in geology. He commences with the concentration of the mass of the globe in a state of great heat; accounts for the fundamental primary rocks by the refrigeration of the surface, and explains the violent action of water upon them by the collapse of this crust on the contracting nucleus. Sedimentary strata are the natural consequence of these watery movements subsiding to rest, and by the repetition of the phænomena such features are imparted to the earth as to insulate many of the later deposits, and render it necessary to be prudent in determining whether local or general agency has been concerned in producing them. It would be difficult in general terms more clearly to announce views now prevalent among those who contemplate geology in connection with physical science. Cordier, Von Buch, and De Beaumont have endeavoured by this speculation of Leibnitz to explain some of the principal phænomena of geology—the elevation of mountains; but the theoretical merit of Leibnitz was little regarded in England till Mr. Conybeare explained his views to the British Association at Oxford. (*Reports of the British Association.*)

The effect of Laplace's and Fourier's theorems on the operation of interior heat is likely to be augmented by Mr. Hopkins's labours (*Camb. Phil. Trans.*); and the grand views of Sir W. Herschel as to the constitution of the universe have already been applied to the history of the earth by Mr. De la Beche (*Theoretical Researches*), and will probably become an important addition to the Leibnitzian theory.

In the works of Ray (1692), and Hooke (1688), we may trace the revival of another general speculation (that of Pythagoras), which, instead of deducing the leading geological appearances from some primal condition, with Leibnitz, supposes the essential condition of the world to be one of continual change, and assigns to modern causes in action a measure of force capable of producing, in a sufficient lapse of time, phænomena as important as those of antient geological date.

Lazzaro Moro's views (1740) have the same tendency to recall speculation to the employment of real causes seen in daily operation; Buffon (1749) appears to have unsuccessfully attempted the union of the fundamental view of Leibnitz and the regard for existing agencies shown by Ray; Dr. James Hutton, of Edinburgh, rejected all inquiry as to the beginning of the world, and gave himself up entirely to an explanation of the phænomena visible in the crust of the earth, on the principle of a continual degradation of land by atmospheric agency, the consequent formation of sedimentary strata on the bed of the sea, and the periodical compensation of these effects by the action of internal heat raising the bed of the sea, with the stratified deposits thereon. A continual destruction of the existing land through the agency of water, and an occasional uplifting of new continents from the ocean bed—these are the most striking points of the Huttonian theory of the earth. Mr. Lyell differs from Dr. Hutton chiefly by recurring to the original form of the speculation as we may conceive it to have existed in the mind of Pythagoras or Aristotle, could either of those great men have become acquainted with modern science. For instead of the occasional occurrence of a violent upward movement of the bed of the sea, the author of the 'Principles of Geology' appears impressed with a distinct idea of a continual compensation among the agencies of nature, the perfect equality of modern and antient physical forces, and the possibility of explaining all, even the grandest, of antient geological phænomena by

causes now acting, and acting with their present intensity. No more definite or general proposition has ever been advanced in geology, and its effect has been highly important, even in the estimation of those who do not entirely admit it.

Inductive Geology.—Geological appearances are usually of a complicated character, and must be analyzed into their elementary parts before the inductive process, which requires the comparison of facts agreeing or differing with respect to a certain quality, can be usefully applied. Fossil shells must be distinguished into fluviatile or marine, identical with or different from recent kinds; rocks must be considered as to their chemical nature, mechanical structure, geographical and other characters, before any valuable inferences can be gathered from them. Though this kind of labour is not discoverable among the works of the Greeks which remain to us, we must not hastily deny that they attempted it. In modern times Fracastoro, Palissy, and Steno, by distinguishing the groups of strata; Lister, by discriminating recent and fossil species of shells, and by noticing the geographical relations of rocks; Woodward, by his industrious collection of specimens and methods of arrangement; Packe, by his remarkable chorographical map of Kent; Lehman (1756), and Arduino, by their classification of rocks, according to the relative periods of their production; and Mitchell (1760), by his masterly determinations concerning the relation between the ranges of mountains and the inclinations of the neighbouring strata—have stronger claims to grateful remembrance than are due to those who with much labour have merely produced volumes of empty speculation.

Distinction of Primary, Secondary, and subsequent Deposits in Germany.—John Gottlob Lehman (1756) may be considered as having the best claim to a clear enunciation and proof of the different age and relative position of classes of stratified rocks. In the French translation of his work ('Traité du Physique, d'Histoire Naturelle, de Mineralogie, et de Metallurgie'), he says, 'Nothing is more natural than to group all mountains in three classes. The first includes mountains which are coeval with the formation of the globe: the second class was produced by a revolution co-extensive with its surface; the third consists of mountains which owe their origin to particular accidents or local revolutions.' This was not a mere speculation of what might be convenient, for, he adds, 'The mountains of the first class are high, sometimes insulated in the plains, but generally connected in a chain, traversing considerable parts of the earth. They differ from those of the second class by their elevation and extent, by their interior structure, by the mineral substances associated with them.'

Pallas (1779*), in addition to these general views, maintains that the granitic rocks, then taken as primary, were never formed by water, because they do not occur in beds, nor contain organic remains; that the secondary mountains were produced from the disintegration of granite; and the strata of later date, by the wrecks of the sea elevated and transported by volcanic eruptions and subsequent inundations.

Succession of Strata.—To these distinguished authors, Werner, professor of mineralogy in Freyberg (1775), was a worthy successor. The first important addition to previous knowledge on the subject was contained in his 'Kürze Klassifikation und Beschreibung der verschiedenen Gebirgsarten' (1787), where the mineralogical distinctions of rocks may be viewed as a completion of the labours of the earlier Swedish writers, Cronstadt, Wallerius, Linnæus, &c., all of whom had glimpses of the geological relations of the rocks they classified. It does not appear that Werner proposed any views as to the geological relations of rocks in advance of those of Lehman or Pallas till 1790 or 1791, when the doctrine of 'formations' was explained in his lectures, which indeed was a powerful mode of diffusing instruction; for his amiable manners, disinterested enthusiasm, and various knowledge, gave him a strong ascendency over the numerous pupils who, from various countries, flocked to Freyberg. In 1795 (or 1796 according to Dr. Fitton) Werner had matured his views as to the classification of all the stratified rocks, and from this it is easy to estimate the real claim of Werner to a high place in the ranks of modern geology. The great advance made by Werner consists, not in propounding the distinctions of great classes of rocks, for this had become a common idea in Europe, but in practically analyzing these classes into their constituent groups, tracing the order of succession among them, assigning their mineralogical characters to each, and generalizing this local truth into the doctrine of formations universally succeeding one another in a settled order of time. Parting from Freyberg with a better method of mineralogy, and a more developed system of the succession of rocks than was previously known, the pupils of Werner carried the influence of his name and opinions over the world, and, unfortunately, the crude hypothesis which was connected with the rich truths he taught was embraced with an ardour very disproportionate to its value.

* 'Journal de Physique,' 1779.

In France, Rouelle (about 1760?) had acquired ideas apparently as general and fully as well supported by local knowledge as Lehman. His views on organic remains were quite in advance of the time. In England the notices of stratification, by Mr. Strachey ('Phil. Trans.,' 1719), the Rev. B. Holloway (1723), and the Rev. John Mitchell (1760), are of great importance. Strachey presents an accurate section of the coal strata of Somersetshire, with reflections on the strata above them, and their geographical boundaries; Holloway describes the geographical relation of the sand-hills of Woburn and Shotover, yielding fullers-earth, to the chalk hills on the east, and the oolitic tracts on the west; but Mitchell enters into a general and masterly discussion on the relation between geological structure and the geographical features of the surface not to be paralleled for fully fifty years.

Whitehurst must here be mentioned with honour. His 'Inquiry into the Original State and Formation of the Earth,' 1778, is of small value for the purpose he proposed, but it contains important facts towards a right conception of the structure of the earth. His 16th chapter, entitled 'The Strata of Derbyshire and other parts of England,' is full of information, principally derived from the miners, but evidently well methodized in his own mind. How could the geologists of England neglect such passages as these following, which are merely the scientific exposition of truths known for hundreds of years previous by skilful miners in all regions of stratified rocks? 'The arrangement of the strata in general is such that they invariably follow each other, as it were, in alphabetical order, or as a series of numbers, whatever may be their different denominations. Not that the strata are alike in all the different regions of the earth, either with respect to thickness or quality, for experience shows the contrary; but that the order of the strata in each particular part, how much soever they may differ as to quality, yet follow each other in a regular succession, both as to thickness and quality—insomuch that by knowing the incumbent stratum, together with the arrangement thereof in any particular part of the earth, we come to a perfect knowledge of all the inferior beds, so far as they have been previously discovered in the adjacent country.' (Edit. of 1792, pp. 178, 179.) In p. 186 is the following remark in capitals: 'N.B. No vegetable forms have yet been discovered in any of the limestone strata.'

From these notices it is very clear that a distinct perception of a fixed order in the succession of strata was so prevalent in the mining districts of England as to attract the attention of the well-informed classes of society, and especially of the clergy, who can never with justice be charged with neglect of the natural sciences. But it is extraordinary that Mitchell, who was appointed Woodwardian professor in 1792 (according to Farey), and, by his physical and mathematical knowledge seemed especially able to work out the whole system of English stratification, should, on his retirement from Cambridge to his rectory of Thornhill in Yorkshire, have contented himself with tracing the succession of strata in the north of England, or rather between Cambridge and Thornhill, and communicating the document to Smeaton, without giving it even to the Royal Society, which had published his early papers. Had this been done, or had Smeaton known the value of the paper put into his hands, it could not have happened, that of all the able engineers who, before 1790, were engaged in surveys and executing canals, not a man should have attended to information of such singular value in his profession; nor would Mr. Wm. Smith have been occupied in rediscovering some of the truths which constitute the foundation of English geology.

The progress of Mr. Smith's discoveries in geology is easily traced. Commencing his career as a surveyor of land, and afterwards acquiring great employment as a civil engineer, his attention was drawn, in 1787, to the obvious distinctions in the soils and the subjacent strata of certain parts of Ox-

fordshire and Warwickshire, which occupied, with regard to one another, a certain geographical relation. In 1790 and 1791 the same relative position of the same strata was forced on his attention in Somersetshire, with the addition of a series of coal strata below the oolite, lias, and red marls with which he was previously familiar. Assured by his own observation, that the local knowledge of the mines of Somersetshire which Strachey had published in 1719 was only a part of the truth, he set himself not to frame an hypothesis but to determine the extent of the regular succession of strata in the vicinity of Bath, drew accurate sections of the strata in the order of superposition, ascertained amongst them a general dip to the east, marked their ranges on a map of the surface, and in 1794, in the course of a professional journey from Bath into the north of England, examined impartially whether the general features of stratification in other parts of England corresponded with the impression fixed in his mind by abundant evidence near Bath, that one general order of succession of the strata could be traced throughout the island, with a general dip to the east or south-east. The result confirmed his view, and excited him to devote time, professional income, and unequalled labour to produce proof satisfactory to others. The result was a geological map of England and Wales, drawn previous to 1801, when proposals were issued for the publication of it.

The strong conviction in his mind of the regular, orderly, and successive deposition of the strata, led him to a more minute analysis of the characteristic marks of the several deposits than had ever been conceived before. The remarkable resemblance and occasional proximity of many rocks near Bath, belonging to different places in the section of strata, and which (to use a favourite expression of Mr. Smith), 'had been successively the bed of the sea,' prevented any merely mineral distinction from being effectual; and he was thus forced to study with care the method of distribution of the fossil organic remains in the rocks, for the purpose of discriminating these similar deposits. This was not long pursued before the local peculiarities of the strata in this respect were connected to a general law, and it was found that, throughout the district in question, the fossils were definitely located in the rocks; each stratum had its own peculiar species, wherever it occured, and could thus be identified when in detached masses and in distant localities. This great discovery was recorded as a thing fully determined in a table of the Order of Strata in 1799, of which copies were distributed beyond the British Islands. The clear idea of each stratum being successively the bed of the sea, is apparently the germ of that happy expansion of geological truths, unmixed with hypothesis and unfettered by a formula of merely local stratification, for which English geology is indebted to Mr. Smith. Such an idea immediately suggests, not a speculation in cosmogony, but various yet harmonious researches in the full spirit of inductive science. The history of successive geological periods, all characterizable by their chemical or mechanical products and contemporaneous organic existence, was thus placed in a concentrated light as a general problem for inquiry, and the effects were immediately obvious, in the employment of organic remains, and sections and maps of strata, to determine the true condition of the land and sea from the earliest periods to the present hour.

Succession of Life on the Globe.—Against the hypothesis of Woodward, that the fossil exuviæ in the rocks were lodged in them by the 'universal deluge,' it was objected, that though the fossil shells, corals, fish teeth, &c. resembled the recent kinds, they were not the same. The question thus raised could not rest. Lister affirmed, that in general the fossil species of shells were entirely distinct from living forms; Camerarius inquired to what marine genus of animals Woodward referred the belemnites, and received for reply that it was a mere mineral! The ammonites were admitted to be not nautili, but were declared to be 'Pelagian shells' not likely to be thrown on the present sea-coasts by the moderate force of tides and storms, which do not influence the deep parts of the ocean. Linnæus continually points out the species of corals and shells to which no recent analogue is known; and Solander, by giving suitable names to the extinct shells of Hordwell Cliff, figured by Brander (1766), opened the way to the researches of Martin, Parkinson, Sowerby, Brocchi, Deshayes, Goldfuss, &c.

Llwyd and Scheuchzer commenced the study of fossil plants, which has lately been so much advanced by Sternberg, Adolphe Brongniart, and Lindley. But by none of those writers who compared the fossil and recent worlds of life under the aspects of zoology and botany only could any clear notion be formed of the existence and destruction of a succession of different races of animals and plants. Lister had noticed the constant occurrence of a certain belemnite in the red layers at the base of the chalk; Morton had distinguished the geological position of some fossils in Northamptonshire; and Llwyd and Woodward had some knowledge of this kind. Rouelle and Werner have claims to attention, but certainly it is to Mr. Wm. Smith that we owe the introduction of the important doctrine, that during the formation of the stratified crust of the earth, the races of animals and plants were often and completely changed, so that each stratified rock became, in his eyes, the museum of that age of the world, containing a peculiar suite of organic exuviæ, the remains of the creatures then in existence.

In France the same truth was put in a bright light by the successful labours of Cuvier and Alex. Brongniart in the vicinity of Paris; the former of whom, by his great anatomical skill, succeeded in restoring the vanished forms of many quadrupeds, different from those which now live; while the latter, collecting materials with great judgment from a wide field of research, brought the most convincing proof of the almost total dissimilitude between the forms of life of the secondary and tertiary periods of geology, while both were for the most part distinct from those of the actual land and sea.

The general doctrine of many successive creations of life in the globe, thus firmly established in England and France, was speedily acknowledged in every country where accurate observations could be made, and it only remained to trace out its consequences, and apply them to particular problems. One very successful effort of this kind has been made by M. Deshayes and Mr. Lyell, who, observing among a vast number of the tertiary fossil shells which are different from existing types, some few which are identical with them, proposed to determine what variation there might be in the proportion of yet existing species among the tertiary fossils from different localities and deposits of a different geological age. As a general result (subject to exceptions) it may be stated, that the more recent the strata the greater the amount of resemblance between their fossil contents and the existing creation,—a result in harmony with general views of the whole subject of the analogy of recent and fossil forms. Hence arises a method of classification for these strata of peculiar interest and power, though its successful application may for a time be delayed, till the philosophy of organic remains be more perfectly developed.

Geological Surveys.—Without maps and sections of particular districts, representing the extent, thickness, and order of superposition of the several component rocks, the abstract truths of geology could never become of general interest or public value. Until the whole of the land be thus surveyed and described geological inferences may be insecure; it is therefore gratifying to reflect, that since Mr. Smith first proposed to publish a geological map of England (1801), a considerable part of Europe has been thus delineated. The first idea of such a map was given by Lister in a communication to the Royal Society in 1683; Mitchell's descriptions in 1760 are such as to make it surprising that no map came from his hands. The Wernerian school of geognosy produced none, we believe, so early as those few maps of the Board of Agriculture in England (1794), which contained delineations of soils, and occasionally of the rocks which gave them their distinctive qualities. In this respect Mr. Smith had no precursor; and when his map of the strata of England and Wales was produced in 1815 it had no rival, and has called up only one original successor, the map of Mr. Greenough. Mr. Griffith is about to publish a map of Ireland; Dr. Macculloch's Scotland is produced; Von Buch's great map of Germany is published; the Mining Engineers of France are just completing their survey of that country; the United States of America have made progress in a similar labour; and the number of topographical works illustrated by maps and sections is innumerable. Before many years have passed the whole accessible surface of the land will have been mapped by geologists.

§ 2. Matter of the Globe.

Geology is distinct from cosmogony; the history of the

successive phænomena happening on a planet revolving round an orb of light and heat may be treated without reference to the condition of the same material particles while they were subject to entirely different conditions. Yet as in tracing the progress of a colony reference may often be made with advantage to the previous history of the same people in another region of the globe, so, in prosecuting geological science in a just and liberal sense, it is advisable to take into account the discoveries of collateral science, so far as these tend to give sure indications of or even to fix certain limits to speculations concerning the origin of the planetary masses.

For the successful prosecution of this inquiry geology must appeal to two entirely distinct branches of collateral science, chemistry and astronomy; which indeed agree in this, that they are both directed to the elucidation of the properties of material substance; but the former is occupied with a study of its elementary constitution, the latter contemplates the relations of its congregated masses.

Chemistry, by analysis of the different sorts of matter visible near the surface of the earth, teaches us that almost every thing is of a compound nature, and formed by the union of two or more elementary particles, endowed with distinguishable properties, and capable of a separate existence and of entering into new combinations. When thus freed from their combinations by processes of art the elementary particles or atoms, of the same kind, form, when reunited, solids, liquids, or gaseous expansions, according as they are affected by temperature, pressure, and perhaps other less general influences. Oxygen, the most abundant of all the elementary substances yet discovered, expands immediately on being freed from union with solid bodies, to a gas which occupies 2000 times the space it previously did; and as nearly half the ponderable matter of the globe consists of oxygen, we must admit, as a plain consequence of this analysis, that upon a general resolution of the compound rocks and minerals into their constituent elements, nearly half the weight of the exterior parts of the globe would expand into gas, and augment the atmosphere till the accumulated pressure should liquify the gas, or prevent further decomposition. What happens to free oxygen with the temperatures and atmospheric pressures which now prevail at the surface, would (we know by trial) happen to chlorine and other substances similarly released from combination, under other temperatures and pressures. As these conditions are now variable, and may be supposed to have passed through all possible grades, it is not improbable that all the substances which exist in the crust of the globe might be converted into gaseous expansions if freed from combination. The great antagonist force to the concentration of matter is heat; by augmenting this agent some substances are decomposed and the parts rendered volatile; in other cases combinations take place which are also volatile; and there are others in which gaseous substances combine with solids at particular temperatures only. Now, as the substances known in the outer parts of the globe are fifty-four in number, as they all separately stand in different relations to heat, pressure, electricity, &c., it is conceivable that under particular conditions the mutual forces of the various particles might be so arranged, and so balanced by the influences of heat and other general conditions, that all sensible solidity and liquidity should vanish, and the whole globe dissolve into an expansion where the particles would be, if not all free, yet in very different combinations from those we now see. This is conceivable as an hypothesis, and chemistry can teach us no more; for as we have not ascertained for each substance, taken singly, what must be the conditions for its appearance as a solid, liquid, or gaseous body, nor have the means of computing what variation in this respect might result from particular admixtures of the substances, it is impossible to deny that the hypothesis may be true, and it would be equally unphilosophical to assert that it is. In this dilemma we must turn to the contemplation of phænomena which may serve to guide us to a just decision. Omitting for the present all considerations of geological phænomena, we must accompany the astronomer in his survey of space, in order to discover if any masses of matter exist which are of the nature of the gaseous expansion assumed; if this be the case, we must further inquire if there be gradations in the appearances they present such as to justify the belief in the possibility of a gradual conversion of a planet into an expansion, or the contrary. To these inquiries the far-seeing eyes of Herschel supply a positive answer. Through various parts of the heavens are scattered large expansions of attenuated matter, called nebulæ, which are irregularly reflective of light, various in figure and degree of condensation. The latter circumstances being carefully studied, it appears that many of them are of a globular or elliptical figure, as if the parts were collected by a general attraction toward a centre; that others in addition, appear to grow continually denser toward a centre, while not a few objects show in the centre the brightness of a solid star surrounded by a thick and extensive haze. Occasionally two or more points of condensation appear in a nebulous mass, thus affording a great analogy with what may be supposed to be the origin of our planetary system.

Comets, which are to be regarded as nebulæ attracted to some one or more systems, supply another and strong analogy with orbitual planets. But it may be reasonably expected that in addition to the graduated appearances of expansion, condensation, and nebulous solidity, there should be proof of corresponding gradations of density. This proof, as far as relates to the nebulæ far distant from our system, can perhaps never be given, though appearances are in favour of the view; even with respect to the comets which enter the solar system, further researches must be made; but the planets themselves supply such a proof, for their density varies exceedingly. The planets nearer to the sun are denser than those farther removed; Mercury, being the heaviest, is almost thrice as dense as the earth, while Jupiter, one of the distant orbs, is about one-third as dense as our earth; and Saturn, which, excepting Uranus, is the most remote, is only one-eighth or one-tenth as dense, and may be considered as light as cork. (Herschel, *Introduc. to Astron.*, p. 278.)

Finally, this general idea of the origin of the mass of the earth from a nebular expansion, suggested by chemical facts, and supported by the appearances in the visible heavens, is confirmed by the mathematical researches of Laplace, who has by this supposition connected together the most striking phænomena of the solar system; the general parallelism of the orbits of the planets, the consentaneous direction of their movement round the sun, of the satellites round the planets, the anomaly of Saturn's ring, and other important circumstances. We have therefore only one test more to which the hypothesis can be subjected, namely, its accordance with what is known of the actual constitution of the earth. This is still no question of geology, but of astronomy. It appears however very certain that neither the figure of the earth, which is that of a spheroid of revolution on its axis, nor the density of the earth, which is greater toward the centre than at the circumference, and so arranged that the surfaces of equal density are symmetrical to the axis of figure, are at all opposed to the doctrine in question, but rather confirm it. From astronomical and chemical considerations, then, it is probable that the mass of the earth once existed as a part of a diffused nebula, like some now visible in the heavens; and as no merely geological evidence as to the changes operated on the condensed planet can be of the smallest value in a question relating to the condensation of a nebula, we must adopt the conclusion as a limiting condition of geological theory.

Consult for further information the article NEBULÆ; Herschel's *Introduction to Astronomy*; Laplace, *Mécanique Céleste*; Nichols's *Architecture of the Heavens*.)

Uniformity of Natural Agencies.—But however firmly we may admit the truth of the speculation of the condensation of planets from a nebular expansion, it can now have but little influence on the progress of geology. For it cannot be employed as the origin of deductions which might disclose circumstances hidden from observation in deep parts of the earth, and explain complicated facts visible at the surface; and this for want of adequate knowledge of the successive effects which must happen among the elementary particles or masses of a nebula during its condensation, as well as of the necessary consequences which such effects must entail on the physical conditions of a planet.

There is however one point of importance which this speculation, if adopted, may assure us of. The condensation of nebulæ is gradual; the density of planets various, the larger ones in general having the least relative weight; the earth must therefore be supposed to have passed through a long range of condensation; and this implies a continual change of intensity among some at least of the physical agencies which belong to it. Whatever was the antagonist

force to the central attraction of the nebular mass, the gradual decline of this force must have been felt, more or less, by all the natural agencies related to it by opposition or sympathy. Even the extraneous influence of light is not independent of the change of conditions produced.

The continual condensation of the mass of a planet necessarily brings with it a change in the relative intensities of the agencies at work among its parts, because they operate under continually varying conditions. Some would lose and others gain in strength, and thus the aspect of the earth must have been continually changing, or subject to periodical renovation. By those geologists who accept the doctrine of the earth's continual condensation, from whatever cause, the uniform intensity of natural agencies taken separately, the continual compensation of their antagonistic effects, and the production of equal effects in equal times, must inevitably be rejected.

Yet though, in strictness, the preceding reasoning forbids assent to Mr. Lyell's general principle, that the former changes of the earth's surface 'are referrible to causes now in operation,' it by no means follows that other causes (that is, other combinations or measures of natural agencies) than those now in operation must be appealed to for explaining the monuments of past revolutions of nature which are preserved to our days. For if these monuments go but a short way back on the scale of time, compared with the periods which elapsed in the condensation of our planet, the causes may not have sensibly varied during the whole course of phænomena traceable in the crust of the earth. This must be decided by a study of the monuments themselves, upon the general and acknowledged principle, that effects are proportional to the causes. Still less is it to be imagined that the study of the effects of modern causes in action is unfruitful in illustrations of the phænomena due to antient causes; on the contrary, there is no other way of learning either the kind or degree of physical agencies concerned in geological operations of early date than the comparison of these with the results of the daily action of the modern powers of nature.

§ 3. Heat of the Globe.

The knowledge of the condition of the earth in respect to temperature is one of the most important steps which can be taken toward a right general contemplation of the history of the revolutions which it has undergone. This knowledge cannot be gathered by geologists labouring as such; it cannot be obtained by meteorological observations, however accurate; nothing short of a mathematical theory of heat, supported by a variety of data concerning the physical constitution and relations of the earth to the sun and space, will be at all available in grappling with the inherent difficulties of the subject. For this theory we are indebted to Fourier.

The heat of any point on the surface of the earth regularly varies from hour to hour, with the rotation of the globular mass on its axis; from day to day and from season to season, with its revolution round the sun; and from year to year to year, with any change in the dimensions or form of the earth's orbit. There are however several causes of irregularity or fluctuation of temperature not demanding notice in a general view.

If in its long course round the sun, the earth passed through parts of the planetary spaces of unequal temperature, this would cause a modification of the periodical, annual, and daily variations.

The atmosphere and the ocean, by their various movements, modify all these circumstances, but not so as to disguise the results when an average of many periods is taken.

In consequence there is for each point of the earth's surface a certain mean temperature, depending on the causes above stated; and the parts under the surface continually tend to acquire very nearly the same temperature as the surface, but not at the same time. The extremes of summer heat and winter cold are not felt till after they have passed away from the surface, and in proportion as we descend, the influence of the daily, monthly, and annual variations grows less and less, because of the slowness of the conduction of heat through earthy substances.

At a certain depth below the surface, these variations become wholly insensible, and the temperature is constant, and nearly the same as the mean temperature of the surface.

If the temperature of the interior parts of the earth be now very different from that constant heat which would result by communication from the surface (heated as before, and subject to the stated variations), this difference would exercise a corresponding though insensible effect on the surface heat, and be more or less sensible at small depths below the inner surface of constant temperature.

Whatever may have been the proper or original temperature of the inner parts of the earth, it is easy to conceive that in very long time the equilibrium of heat should be reached, and the earth receive from the sun and radiate into the ethereal space equal quantities of heat in equal times; while the temperatures at points situated at very great depths below the surface (many miles, for instance) would not sensibly vary from that of the mean heat of the place vertically above them.

But if this equilibrium be not attained, the original state of the earth as to heat may be ascertained, so far as to determine positively whether it has formerly been hotter or colder than at present, by merely trying at many points exempt from volcanic action, what is the amount of heat at various depths, on the same or different vertical lines, as compared with the corresponding points of surface.

These trials have been made at various depths, under different circumstances, in salt-pits, coal-works, and mines of different metals, in the British Isles, France, Germany, Mexico; and in all situations where the external influence of the air, and the artificial effects of light, respiration, &c., could be guarded against or justly appreciated, they agree in proving that after descending below the limit of variable heat, a continual augmentation of temperature constantly occurs. (1° Fahr. for 15 yards is a common ratio.) The mine of Falun, supposed to be an exception to this general truth, is extremely ill-suited for experiments. (See Thomson's and Clarke's *Travels in Sweden*.)

The consequence is obvious. The interior masses of the globe are incomparably hotter than the parts at the surface; must formerly have been still hotter; and though now the interior heat is almost wholly masked and stifled by the non-conducting stratified masses which form the crust of the earth, it must formerly have influenced in a decided manner the temperature, and with it all other phænomena at the surface of the earth.

The same conclusion as to the existence of great heat in the central parts of the earth has been drawn from considerations of the density of the interior masses, as compared to the superficial parts. While the surface rocks are twice and a half as heavy as water, the mean density of the whole globe is five times as great as that of water; moreover the density augments toward the centre with so much of regularity, that the imaginary interior surfaces of equal density are symmetrical to the same centre and axis as those of the exterior spheroid. (See Conybeare's *Report on Geology to British Association*, 1832.) Now if the interior masses of the earth are compressible even to a far less extent than the rocks near the earth's surface, the pressure to the centre would have made the inner parts much more dense than they are: the whole mass of the earth would have been included in a much smaller volume, were it not for some antagonist force, such as heat is known to be. Unless therefore we venture to suppose the central and surface matter not subject to similar laws of force, it must be admitted that the interior parts of the earth are still very hot.

Condition of the Interior Masses.—This great truth established, we may inquire further into the state of the interior masses. If the heat of the globe were increased, its diameter would be augmented; there is a degree of heat which would liquefy nearly all the substances of which it consists, taken singly, and still more easily when in their usual combinations. Beyond this degree of heat gaseous compounds would mix with, or altogether replace, the liquid rocks, and the globe would be lost in a nebulous expansion.

Turning to observation of phænomena, we find the interior rocks to be such as were cooled from igneous fusion: they are extensively, perhaps universally, spread below our feet; and thus we gather the conviction that originally the whole or great part of the exterior masses of the planet were in a melted state. The figure of the earth is such as would result from revolution on its axis, provided the whole or a very large part of the mass were in a state of fluidity or viscidity; to this figure the surfaces of equal density correspond both as to centre and axis; and thus strongly corroborate the speculations of Leibnitz, that the earth is to be

looked on as a heated and fluid globe, cooled and still cooling at the surface by radiation of its superabundant heat into space.

Refrigeration of a Planet.—To determine whether it is now solid or partially fluid within is a problem of high interest, and one which we may perhaps despair to see completely solved, unless certain astronomical phænomena (precession, nutation) should be found, when analyzed by a rigorous mathematical deduction, to furnish interpretations which geology alone can never attain to. As however Mr. Hopkins, who is engaged in this abstruse research, has presented some simple views of the possible conditions of a cooling globe (as the earth may be considered), we shall here briefly state them.

If the earth were originally a hot fluid mass cooled by radiation, the cooled parts would descend towards the centre, and be replaced by others in a perpetual circulation. The tendency to solidification in such a mass would be directly as the pressure, inversely as the temperature, both which are at a maximum at the centre: solidification would therefore be determined near the centre by the superiority of pressure over temperature; and at the surface by the rapidity of external refrigeration overbalancing the internal conduction of heat. The numerical relations of these qualities are unknown. It cannot therefore be decided by mere calculation whether the solidification of the surface by radiation would precede or follow that of the centre by pressure. Let us suppose, for simplicity, the relations of pressure, heat, circulation, conduction, and radiation, to be such that all the mass goes on cooling till in every part of its fluidity is lost, and the whole is reduced to such a degree of viscidity as to prevent the circulation of heated matter, the further distribution of heat must, under these conditions, be determined by conduction and radiation only; a large part of the interior would assume equality of temperature: the solidification of the surface by cooling would be the first new phænomenon, to be immediately followed by condensation through pressure about the centre; and thus two solid masses would be produced and continually augmented—a spherical nucleus, and a spherical shell—while between them would remain a large but diminishing zone of viscous matter, subject to some changes of temperature through the conversion of its surfaces from a liquid to a solid state.

If, on the other hand, the effect of pressure to the centre became superior to the expanding agency of heat, before the circulation of liquid matter had ceased in the superficial parts, the centre would solidify first; and the induration might proceed through a large part of the globe, so as even to approach the surface before that could be consolidated. If these conditions were reversed, consolidation might proceed from the surface downwards, and would ultimately reach the centre, and the whole mass be a stony globe.

It is important to remark that upon neither of these suppositions is it required to admit the continual augmentation of heat to the centre; to which M. Poisson objected, and instead of which he proposed to account for the phænomena of the earth's interior temperature by supposing that the solar system had once passed through other ethereal spaces than those which it now occupies, and there experienced much higher temperature at the surfaces of the planets. This hypothesis may be perhaps not very different in its development from the more general theory of the nebulous origin of the planets; but it appears unnecessary to discuss the speculation after what has been said of the cooling of the earth.

§ 4. Modern causes of Changes on the Surface of the Earth.

The never-ceasing activity of the powers of nature may be viewed as an inextinguishable and unavailing effort to restore an equilibrium which is incessantly disturbed. The protean changes of the atmosphere; the varying effects which its chemical and mechanical energies occasion among the masses of dead matter and the forms of life; the flowing of the ocean; the subterranean fire and wide wasting of the earthquake, are all efforts to obtain rest consequent on a succession of perturbations. In this sense, not the earth only, but all the solar system, and perhaps all the extent of the heavenly spaces, conceivable rather than visible by man, is in the condition of instability described in the Pythagorean Philosophy, 'Nihil est toto quod perstet in orbe.'

These changes on the surface of the earth affect the geographical boundaries of land and water, the relative levels of land and sea, and the forms, proportions, and distribution of animal and vegetable life. In a popular sense they may be classed by their proximate agencies, as depending on chemical and mechanical powers originating from atmospheric action, rains, springs, rivers, &c.; as depending on similar powers residing in the ocean; and as affected by volcanic forces. We may also venture to contrast the effects of the watery agencies, whether of atmospheric or oceanic origin, with the products of volcanic fires. For the general effect of the watery agencies is to abate the high and to raise the low, to equalise the level of land and sea by abrading the former and filling the latter; but volcanic effects are directly the reverse. They augment the original inequality of the surface; in some parts they raise matter from within the earth, and form new hills to bear the ravages of the atmosphere; and elsewhere cause tremendous depressions of land, and sink in deeper hollows the original basins of the ocean.

The external influences, thus contrasted with the interior powers of the globe, are far more various in their aspect and more general in their visible operation; yet they may all be reduced to one or two variable forces, independent of the terraqueous system. It is to the unequal accession of heat from the sun, upon a globe whose distance varies, whose parts are variously presented to the radiating beams, and to the unequal abstraction of heat by the cold ethereal spaces in which the earth circulates, that we may refer all the variations of corpuscular and mechanical phænomena on the globe; while in the varying diffusion of light we recognise the prime element of change in the animal and vegetable world.

Minute as is their momentary impression, the sum of their effects in a long time is prodigiously great; heat and moisture by alternate influence weaken; frost bursts; carbonic acid eats with cankering tooth; rains, swallowed up by the fissured rocks, abstract parts of their substance; landslips, avalanches, and glaciers heap the valleys with detritus, till swollen rivers or bursting lakes sweep away the burden towards lower ground, or convey it even to the sea. Thus chemically dissolved, mechanically suspended, or roughly rolled along, the substance of all the rocks and mountains yields to a slow but sure destruction, and those who, adopting the notion that 'time costs nature nothing,' take as much of this as pleases them, may easily see, in the effect of these operations, the total disintegration of the existing continents and islands, which is so conspicuous a feature in Dr. Hutton's hypothesis of the decaying and renewing earth.

Nor is the sea less a theatre of change than the land. For, independent of its receiving the spoils of the land, and distributing them on its bed, the untiring agitation of its waves undermines the cliffs which are above its level, grinds away the rocks which are covered and uncovered by the tides, and distributes the materials in various ways, here making dangerous sandbanks, there adding to the low shores a valuable heritage.

Nor even below the deep water of the middle ocean is all at rest. There multitudes of sea animals, the zoophyta, testacea, &c., by their mere exuviæ tend to fill up the depths; and certain tribes (the lamelliferous corals in particular), by their peculiar growth and mutual adherence form calcareous islands and reefs, similar in some important particulars to the antient limestone rocks. These coralligenous rocks are however not reared from the extreme depths of the sea, but based on the summits of submarine hills, or the crests of volcanic cones, and thus, in a general expression, we may say that in modern nature most of the deposits of solid matter in the sea are joined to the shores or shallows of the previously-formed land.*

The sediments transported by rivers, and gathered by the wasting of the elevated coasts, being for the most part deposited along the sea-shores, and almost wholly below the level of high water, it is obvious that from this cause alone the bed of the sea is filling up, and its depth diminishing toward the shores; but as the quantity of water on the globe must be supposed sensibly constant, it follows that the oceanic area must expand, or its surface rise a little. But since the land is wasted by the waves, as we may suppose the augmentation of area which results from this cause sufficient to balance the elevating tendency of the littoral deposits of sediment, and that upon the whole the effect of the watery agencies on

* For details in proof of what is here advanced, consult Lyell, 'Principles of Geology,' and the articles Polyparia, River, &c.

the globe is insensible in altering the level of the surface of the sea, as compared to the deeper parts of its bed; it follows, as a strict consequence, that the area of the ocean is enlarging. This appears also probable from observation; for the small addition of marsh land on particular shores, by the influence of rivers, winds, and storms, in raising littoral sediments above the reach of all but the extremely high tide, is not enough to balance the continual waste of land along many thousand miles of perishing cliffs. By the mechanical agency of water considered alone, the land is certainly losing in area continually. The accumulation of marine exuviæ on the bed of the sea acts in the same direction, and the growth of coral principally concurs in the same result. Left to watery agency alone then the land may be imagined to be continually diminishing, as Dr. Hutton and Mr. Lyell suppose. If the shores of the sea did not waste away, the annual additions of sediment brought from the uplands would everywhere cause the water to rise in level; if the land were supposed to overhang its base at a certain angle depending on the diameter of the earth, the area of the ocean would remain invariable; but as neither of these conditions applies, it is certain that the area of the ocean is extending, and probable that its level does not materially change.

Volcanic phænomena, the earthquake and the ignivomous mountain, are to be viewed as cases of critical action. Whether the heat of the interior of the globe be the residual portion of its original temperature (*chaleur d'origine* of Arago), or generated by the access of water, or other bodies containing oxygen, to certain chemical substances, it is to the disturbance of its equilibrium that the violence and the tumult of volcanic excitement are owing. But there are other and more gradual effects of the distribution of heat in and upon the globe which require notice. The most important of these is the gradual change of level of certain parts of the land, as compared with the general level of the ocean, one instance of which is supposed to occur on the shores of the Baltic, where certain tracts appear to be slowly rising above the sea. (Lyell, in *Phil. Transactions*, 1835.)

Concerning this 'secular inequality,' (as it may be termed) of level of land and sea, it is unfortunate that nothing at all important is known toward determining the important question whether the elevation of one tract of dry land or sea-bed is balanced or overbalanced by the depression of another. Mr. Lyell assumes that the depression of land from this cause exceeds the elevation, but it is difficult to find sufficient evidence for this important postulate; and to adopt it merely as a consequence of another unproved assumption of a continual compensation of the agencies of nature, is altogether inadmissible.

If there be in the earth a pervading high temperature, which diminishes from the interior toward the surface, in consequence of the radiation from the surface, it appears from Sir John Herschel's reasoning (given in Mr. Babbage's 'Ninth Bridgwater Treatise'), that along the shores of the sea the isothermal lines of the interior of the globe should rise, because of the continual deposition of imperfectly conducting sediments there. For thus the radiation of heat along these lines would be diminished until the interior heat had come nearer to the surface. By the consequent expansion of the subjacent earthy substances the sea-shore should rise, and thus the addition of sediment from watery action, and the effect of the effort to restore equilibrium in the disposition of the interior temperature, would, upon the whole, coincide in minutely raising the surface of the sea.

It is chiefly near the sea-coast, on the land or in the ocean, that volcanic phænomena are at this day seen in activity, and this apparently because the admission of water to some depth below the surface is necessary to the excitement of the imprisoned forces of heat. The elevated cones and large areas of melted rock, or accumulations of scoriæ and ashes, mark one of the prevalent effects of the volcanic forces to be the withdrawal of matter from the interior, to heap it on the surface of the earth. But the cavities left by this operation below the crust of the earth must often cause depression of masses of land during the concussion and displacements occasioned by earthquakes. In this manner it may easily be understood that the volcanic islands of the South Seas have been raised up from the sea-bed there, and it may be supposed that under large tracts of the ocean volcanic agency is employed in a similar way, and by a superiority of elevation over depression, raising irregularly the bed of the sea, and by consequence extending the area of its surface. If all the cavities left below the surface by the heaping of volcanic matter on the land were completely balanced by corresponding depressions of the crust of the earth, it would depend upon the proportion of submarine subsidence corresponding to terrestrial elevation whether the sea-level should fall, and its area contract. Every sinking of the sea-bed corresponding to an elevation of the dry land would tend to lower the level of water, and to augment the area of land. Along sea-coasts such correspondence must be admitted occasionally to occur. If the cavities alluded to were not compensated by the sinking of the superincumbent crust, volcanic phænomena on the land would hardly affect the area or level of the sea; but similar eruptions in the sea would raise its level and cause it to encroach upon the land. If it be admitted as the most probable basis of reasoning, whether subterranean cavities exist or not, that the continual elevation is upon the whole balanced by continual subsidence, submarine and continental volcanic vents may be left out of consideration; but the littoral and insular volcanoes act in one certain way, and give as the general result of all volcanic action, a partial deepening and a general contraction of the sea, which counterbalances in kind the general effect of the aqueous agencies; but whether these completely antagonist principles are equal in degree can not be safely inferred from any data now accessible to geology. Nor does it appear prudent to rest so important a conclusion on the mere fact of the constancy of the earth's dimensions, indicated by the invariable length of the solar day; the experience of 2000 years is as nothing in a question of such infinitesimal differences of diameter as might be occasioned by changes in the relative position of the really small quantities of matter raised or sunk by volcanic powers.

Moreover it is impossible to avoid doubting whether even the quantity of water on the globe is constant; for so many combinations of earthy substances require certain proportions of water for their completion, and so much of volcanic excitement appears due to the decomposition of water, that it would perhaps be safer to suppose the water continually diminishing in quantity; nor is it at all unlikely that such may be the case with the atmosphere.

§ 5. Comparison of Effects of Natural Agencies in Modern and Antient Times.

The statement of the effects of modern causes must necessarily be received as true and applicable to other æras of the world, at least in its general features; because the chemical, mechanical, and vital forces of nature are admitted as individually constant, though their manifestations to our senses be ever so various in kind or degree, in consequence of change in their combinations, the quantities of matter operated on, external influences, &c. Fixed laws and variable conditions are certainly recognised in existing nature, and they give rise to extreme inequality in local results and combinations. It is conceivable, by extending this idea, that the existing laws of nature should be productive not only of results which, taken locally or periodically, appear unequal in degree or diverse in kind, but that under the influence of a general change of conditions they should manifest a gradual decay or increase of strength, or spring into extraordinary activity after long periods of apparent slumber. Let, for instance, the sun's rays be supposed to fall upon the earth in smaller quantity through the augmentation of the minor axis of the earth's elliptic orbit; let the temperature of the ethereal spaces rise: who does not see that all the effects depending on the external excitant forces would immediately change? In like manner, let the earth's internal energy of heat be supposed to die away, whether for lack of fuel, incrustation over metalloids, or a loss of general warmth in the globe, the volcanic phænomena would be weakened, and no longer balance the effects of water.

Now as these great conditions cannot be affirmed to be constant, but, on the contrary, as one at least of them is known to be variable (the earth's orbit), how 'baseless as the fabric of a vision' is the assumption that the physical agencies on the globe have always produced 'equal effects in equal times,' and that modern causes acting with their present intensity have produced all the older phænomena of geology. But it would be equally unjust, as observed before, to assume that they have not; the question, if capable of determination, can only be settled by ample observation and logical induction.

Among the antient phænomena of nature we equally recognise the contrasted action of water and heat, as at this day: by the former the solid land was wasted, and stratified rocks were deposited along the sea-shores (as sandstones) and in the depths of the sea (as some limestones), while the latter manifested itself in the production of unstratified crystalline rocks and the elevation and disruption of the stratified bed of the sea. [ROCKS; STRATIFICATION.] The materials arranged by the action of water in the stratified rocks of antient date are the same as those now carried by rains, suspended by the tide, or separated from sea-water by the vital functions of invertebrata; they are, to a certain extent, similarly associated: the organic exuviæ buried in them are not very differently arranged or grouped from those which now lie in the bed of the sea (Donati's *Researches on the Bed of the Adriatic* may be quoted in proof of this); the physical conditions of their accumulation were therefore in a considerable degree similar.

On a careful consideration of the facts, it appears obvious that the long series of stratified deposits was not accumulated without great and even sudden changes of those physical conditions: thick deposits of sandstone are followed by others of clay or of limestone, for which different agencies and conditions were required. Over the same spherical area of the earth's surface the predominant physical conditions varied from time to time, and many times, so that the actual state of the globe, as far as regards watery agencies, represents not all its previous conditions, but is to be compared with each of them successively. The same is true of the igneous products in the crust of the globe, which similarly varied from time to time in the same spherical area.

Successive phases of the aqueous and igneous agencies over the same region appear, either contemporaneously or successively, to have affected all parts of the earth's surface accessible to man; so that everywhere there is proof of great revolutions in the condition of land and sea. Moreover it appears [ORGANIC REMAINS] that to each general system of stratified rocks, indicative of a corresponding great system of physical agencies, peculiar races of plants and animals belong:—with new physical conditions, new forms of life came on the globe, vanished with those conditions, and gave place to others equally transitory. If now we compare the modern survey of nature with any similar work, executed on the same principle, for any one of the earlier epochs, it is certain that the earth has undergone many very extensive revolutions in all that respects its aqueous, igneous, and organic phænomena, before arriving at its present state: it is equally certain that between the epochs of these revolutions, the state of the earth was not extremely dissimilar to that which we now behold; yet, because the organic beings preserved in the earth in each of these systems are peculiar to it and differ from the others, and from those that now live, we cannot possibly doubt that the points of difference were numerous, general, and important.

To determine the cause of the change of physical conditions between one system of stratified rocks and another is not difficult. In existing nature such a change might be easily produced in almost every region by a disturbance of the level of some particular tracts of land, by one great movement or many successive displacements. For example, let the isthmus of Suez or the isthmus of Darien sink one hundred or a few hundred feet (perhaps scarcely beyond the range of the power of an earthquake), what mighty changes would be occasioned in the Indian, Mediterranean, Atlantic, and Pacific Oceans, over areas which would appear considerable even when compared with many antient systems of strata—changes of stratified deposits, and physical conditions, and consequent variations in the relative abundance and geographical distribution of organic beings. Now, though at this day no such mighty changes are witnessed, we have only to enlarge our conception of the actual effects of volcanic agency to see clearly that this is the power which was employed in producing them.

§ 6.—SURVEY OF SUCCESSIVE PERIODS OF THE FORMATION OF THE CRUST OF THE EARTH.

The analogy of the effects of aqueous and igneous agencies in all past periods of the earth's history being assumed, we may proceed to gather inferences as to the measure of the intensity with which they have operated, and the time which has elapsed during their operation. This requires at least a brief summary of the characteristic features of the phænomena of successive steps of the earth's formation, in the order of their occurrence. Observation can only guide us to a knowledge of the crust of the earth for a depth of a few miles at most; and from what we there behold it is probable that a much greater extension of the power of observing would really help us but little in tracing the history of the revolutions of our globe of which monuments remain for inspection. For at some moderate depth below the surface all marks of lamellar increase, indicative of periodical formation, cease; all monuments of life and watery action terminate; and we behold the effects of heat alone. The general basis of all the crust of the earth, in which we trace the combined results of igneous, aqueous, and vital energies, is a mass of crystallized rocks, the fruit of great and very general heat; which limits all inquiry in that direction.

From the surface of these interior crystalline rocks mostly of the nature of granite [ROCKS; STRATIFICATION], the monuments of physical changes left in the rocks are capable of interpretation by the application of the knowledge we have gathered of chemical, mechanical, and vital forces, but below it all appears at first sight dubious and dark. Were these rocks of igneous origin anterior to the whole crust of the earth now placed upon them? Or does the interior heat slowly reconvert to granite the masses of sedimentary strata laid upon it by external watery agencies? In the former case the monuments of nature are complete so far as any thing analogous to the present system of surface agencies is concerned; but according to the latter supposition, the earlier strata, with whatever of organic exuviæ lay in them, have been reabsorbed and melted into the hidden secrets of the earth, and a similar fate awaits their successors.

To assume the truth of either of those views is altogether contrary to the prudent spirit of modern philosophy: no inspection or analysis of the old granitic masses; no merely analogical comparisons of them with the fluid compounds of existing volcanoes; no *à priori* reasoning will solve the question. Yet it appears capable of solution by a full and impartial consideration of the stratified crust of the earth itself, which ought to show, in the nature and condition of the lower strata as compared with the upper, and in the nature and abundance and mode of conservation of organic remains, evidence not only of the circumstances under which they were accumulated, but indications of the nature and extent of the changes which have since occurred to them. This mode of inquiry we shall endeavour to follow.

This first diagram on the following page is intended to show how very small is the supposed depth of the crust of the earth, and of the most profound parts of the ocean, compared to the radius of the globe. The thickness of the crust of the earth, here taken at 15 miles, is perhaps, on a general average, not so much as five. To this mere film on the surface of the globe inductive geology is confined; though by help of collateral science we have learned many truths as to the constitution of the hidden interior masses.

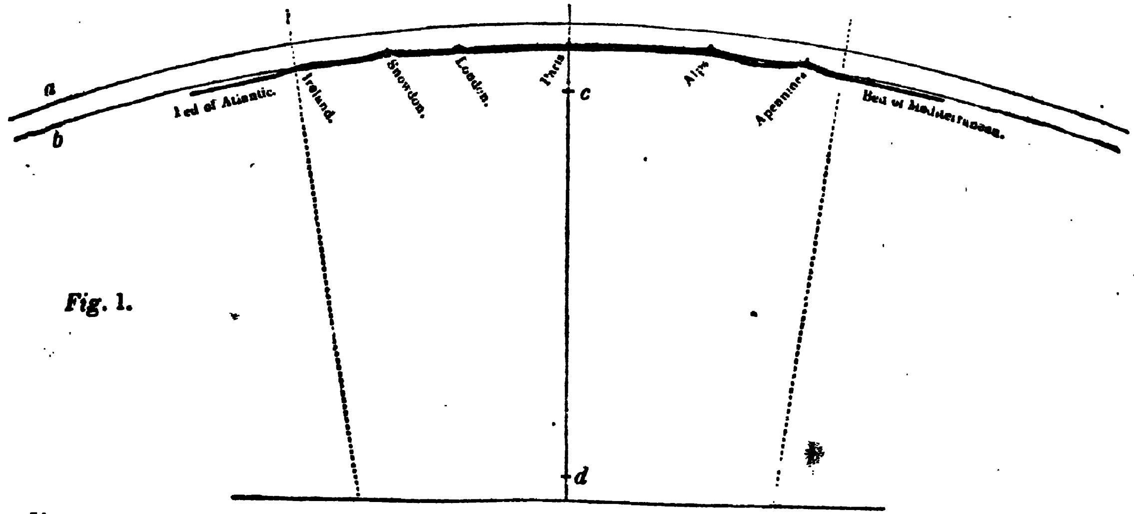
The difference of the diameters of the earth is nearly 26 miles. If the axis of the globe were displaced 90°, the level of the sea would rise at the old poles and sink at the new poles about half that quantity, or 13½ miles; and at other points, intermediate quantities, according to their relations to the great circle passing through the new and old poles of rotation. At the poles of this great circle there would be no alteration of level.

By imagining the depth of 1000 miles, in the first diagram on the following page, to be repeated three times, and the three radii to be at the same time prolonged till they meet at a point, which would represent the centre of the earth, the reader will easily form a notion of what is intended.

The arc includes 20 degrees from the Adriatic to the Atlantic, passing over the Apennines, the Alps, the English Channel, the Welsh Mountains, and the Irish Sea, the depth of the narrow seas being less than the breadth of the fine lines.

The subjoined general section (*fig.* 3), combined with the complete table of British strata which follows (extracted from Phillips's 'Guide to Geology,' 3rd edition, p. 19) will serve for reference to the reader who may be unacquainted with the arrangement of the stratified rocks in the crust of the earth.

Fig. 1.



a, Line representing the supposed limits of the atmosphere, 45 miles above the earth. *b*, level of the sea. *c*, depth of 100 miles on the radius; the black part being the supposed thickness of the earth's crust. *d*, depth of 1000 miles.

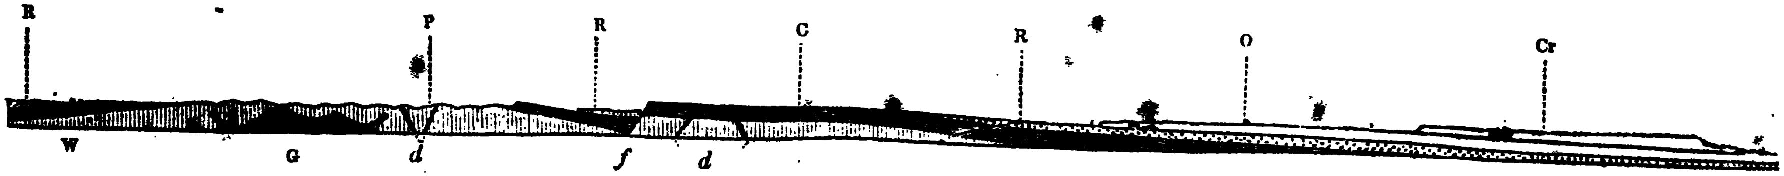


Fig. 2. A general section of the crust of the globe, about 100 miles in length and one mile in depth, from Bridlington, B, to Whitehaven, W, on a true scale, that is, the height proportioned to the distances.

G, the granite, appearing under the slaty primary rocks, P, of Cumberland, which rise to the height of 3160 feet. C, the carboniferous system, rising to the height of 2901 feet in Crossfell. R, the red sandstone, or saliferous system, usually found in very low ground. O, the oolitic system, rising to 1485 feet in the Hambleton hills. Cr, the cretaceous system, which, at its highest point in the York Wolds, is 805 feet above the sea. *d*, dykes of basaltic or porphyritic rock. *f*, a great dislocation.

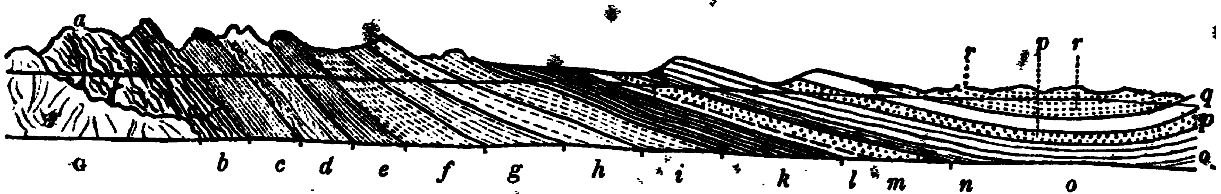

Fig. 3. General view of the succession of British strata, with the elevations they reach above the level of the sea.

G, Granitic rocks; *a*, gneiss; *b*, mica schist; *c*, Skiddaw or Cumbrian slates; *d*, Snowdon rocks; *e*, Plynlymmon rocks; *f*, Silurian rocks; *g*, old red sandstone; *h*, carboniferous limestone; *i*, millstone grit; *k*, coal-measures; *l*, magnesian limestone; *m*, new red sandstone; *n*, lias; *o*, lower, middle, and upper oolite; *p*, greensand; *q*, chalk; *r*, the tertiary strata.

Series of British Strata, beginning at the Surface, from which all Water-moved Gravel and River Sediments are supposed to be removed.

[The Marine Strata are marked by Figures; the Fresh-water and Æstuary Beds by Letters; the names of some characteristic Fossils are in Italics.]

TERTIARY STRATA.

A small number of the Fossils are identical with existing species.

Names of Formations.	*General Thickness. Yards.*	*Remarks.*
1. Clay	16	A water-drifted mass of marine shells, pebbles, &c., resting on more regular shelly beds of sand or sandy limestone. About 40 per cent. of the shells are supposed to be identical with existing species.
a. Fresh-water marls	33	They include a bed of æstuary shells, and occur only in the Isle of Wight.
2. London clay	100 to 200	Mass of clay rich in marine shells, of which 3½ per cent. are identical with recent kinds.
2. Plastic clay	100 to 400	Variously coloured sands and clays, the latter containing organic remains identical with or much allied to those of the London clay.

SECONDARY STRATA.

All the Fossils belong to extinct species. They are different from those in the Tertiary Strata.

System	*Names of Formations.*	*General Thickness. Yards.*	*Remarks.*
Cretaceous System.	3. Chalk	200	Of unequal hardness, soft above, marly below, with interstratified flints; extinct Zoophyta, *Ananchytes*, and other Echinodermata.
Cretaceous System.	4. Green sand	160	Upper green sand, very fossilliferous, in general chalky. Gault, a blue marl, or clay, often very fossilliferous. *Belemnites minimus*. Lower green sand, or iron sand, very fossilliferous in places.
Oolitic System.	*b.* Wealden	300	Weald clay, with fresh-water shells. *Cyprides*. Hastings sands, with land plants, and bones of *Iguanodon*. Purbeck beds of clay and limestone, with fresh-water shells.
Oolitic System.	5. Portland oolite	130	A variable locally oolitic limestone; some beds full of fossils. Kimmeridge clay, with layers of *Ostrea deltoidea*.
Oolitic System.	6. Oxford oolite	150	Upper calcareous grit. Coralline oolite, with beds and masses of coral; *Echinida*; many shells. Lower calcareous grit. *Ammonites catena, Pinna lanceolata*. Oxford clay. Kellaway rock. } *Ammonites Calloviensis, Gryphæa dilatata*.
Oolitic System.	7. Bath oolite (near Bath)	130	Cornbrash, thin, impure, shelly limestone. *Avicula echinata*. Forest marble. Shelly oolite, with concretionary sandy limestone. Bath oolite. In several divisions, shelly, oolitic, compact, and sandy beds. *Megalosaurus, Apiocrinus*. Fuller's earth. A series of calcareous and argillaceous shelly beds. Inferior oolite. Pholadomya. *Trigonia striata*. Sand, with concretionary masses holding shells.
Oolitic System.	8. Lias	350	Upper lias shale. Full of characteristic saurians, of *Ammonites, Belemnites*, and other shells. Marlstone, replete with *Terebratula*, Pectinida, *Avicula inæquivalvis*. Middle lias shale. Contains *Gryphæa, Ammonites*. Lias limestone, with *Gryphæa incurva, Ammonites Conybeari*. Lower lias shale, and coloured marls.
Saliferous, or New Red Sandstone System.	9. New red sandstone	300	Coloured marls, gypsum, and rock salt. Red and white sandstones, and marls. Conglomerate and sandstone. } Few or no organic remains.
Saliferous, or New Red Sandstone System.	10. Magnesian limestone	100	Knottingley limestone. A few bivalves in the lower beds. Gypseous red marls. No fossils. Magnesian limestone. Shells, corals. Marl slate. *Fishes* of remarkable forms. Red sandstone. Plants of the subjacent coal series occur in it.
Carboniferous System.	*c.* Coal	1000	The subdivisions of the coal series are only locally ascertained. Gritstone and shales constitute the principal mass. Flagstone and ironstone are among the most characteristic layers. Freshwater limestone and marine limestone are exceedingly rare and local. The shells are mostly of æstuary origin. The plants are mostly of terrestrial tribes and extinct genera.
Carboniferous System.	11. Carboniferous or mountain limestone	800	Millstone grit, series of sandstone, shales, coal, and thin limestones, forming a transition group between the coal and the carboniferous limestones. Yoredale rocks, consisting of five or more beds of limestone, with alternating flagstones, and other gritstones, shales, thin coal, ironstone. Lower or scar limestone, in the North of England and Scotland, subdivided by sandstones, shales, and coal seams. They yield characteristic *Crinoidea, Productæ, Spiriferæ, Orthocerata, Bellerophon, Goniatites*. Alternating limestones and red sandstones, forming a transition group between the carboniferous limestone and red sandstone formations.
Carboniferous System.	12. Old red sandstone	100 to 3300	Conglomerates and sandstones. No fossils yet noticed. Coloured marls and concretionary limestones, called "cornstones." A few fossils. Tilestones, or flagstone beds. A few fishes.

See, on the subject of this classification of the Carboniferous System, the second volume of the 'Geology of Yorkshire,' 1836.

PRIMARY STRATA.

All the fossils belong to extinct species, and often to extinct genera and families. They are different from those in the Secondary and Tertiary strata. It has been usual to class the upper systems under the title of Transition strata, and to confine the name of Primary to the mica schist and gneiss systems. The following view of the subject results from Mr. Murchison's researches:—

System	*Names of Formations.*	*General Thickness. Yards.*	*Remarks.*
Silurian, Upper Grauwacke, or Transition System.	13. Ludlow rocks	660	Sandstones. Species of *Orbicula, Lingula*, Terebratula, Spirifera. Limestone. *Pentamerus, Homonolotus*. Shale.
Silurian, Upper Grauwacke, or Transition System.	14. Wenlock limestone	600	Limestone. Shale. { Corals and Crinoidea in vast abundance. *Euomphali, Producta depressa*, Orthocerata, *Calymene Blumenbachii*, and other Trilobites.
Silurian, Upper Grauwacke, or Transition System.	15. Caradoc sandstone	880	Shelly limestone. Various sandstones. } *Pentamerus*, Terebratula, *Orthis, Trilobites*.
Silurian, Upper Grauwacke, or Transition System.	16. Landeilo rocks	400	Calcareous flaggy beds, including *Asaphus Buchii*, and other Trilobites.

The stratified argillaceous rocks below, from the rarity of organic remains and other causes, are not yet completely understood. The following arrangement, based on the labours of Sedgwick, is however almost certainly correct with reference to the succession of deposits in the Welsh and Cumbrian districts. The thicknesses are insufficiently known.

System	*Names of Formations.*	*Remarks.*
	17. Plynlymmon rocks	Argillaceous indurated slate, sandy slates. No fossils yet found in it. Calcareous and argillaceous rocks, with Orbicula, Zoophyta, and other organic remains.
Cambrian System.	18. Bala limestone	Calcareous and argillaceous rocks, with *Orbicula, Zoophyta*, and other organic remains.
Cambrian System.	19. Snowdon rocks	Variously coloured and indurated argillaceous slate. A few fossils have been observed in Wales.
	Clay slate	Soft dark slate. No fossils known.

Skiddaw System.	Chiastolite slate	Soft dark slate, with chiastolite. No fossils known.
	Hornblende slate	Soft dark slate, with hornblende. No fossils known.
	Mica schist system	No or nic remains. The beds of mica schist, composed of mica and quartz, alternate w h gneiss, chlorite schist, talc schist, hornblende schist, clay slate, quartz rock, a primary limestone.
	Gneiss system	No or nic remains. The gneiss beds, composed of mica, quartz, and felspar, alternate lo lly with mica schist, quartz rock and primary limestone.

Primary Periods.

Oldest Systems of Strata.—Gneiss and Mica Schist.—Gneiss and mica schist, two of the most abundant of the oldest stratified rocks, appear, as to their substance, to be composed of the same parts as granitic rocks, viz. felspar, quartz, and mica, with great variations of proportions, and some admixtures and substitutions of other minerals, constituting alike granite, gneiss, mica schist, &c. But the ingredients are not in the same condition;—in the granite all is crystallized; each mineral is independently a crystal, or moulded in the cavities left between crystals; in gneiss and mica schist the felspar, quartz, and mica are rolled or fragmented masses. The character of worn surface of the ingredients, combined with the lamination or stratification of the mass, assures us that aqueous agencies have determined the aggregation of gneiss and mica schist: the character of the lamination, especially the minute flexures which abound in these antient rocks, suggests somewhat of peculiarity in the condition of the water; and the internal crystallization of the attrited felspar reveals its origin from the disintegration of granite.

On the other hand it has been contended that the similitude of the mineral composition of gneiss or mica schist to granitic compounds argues a similitude of origin; and by some writers gneiss, mica schist, &c., are regarded even as igneous rocks; by others it is thought that gneiss and mica schist are intermediate products between sandstone and granite, retaining the lamination and bedding which indicate their original aqueous origin, but assuming a new mineral composition in consequence of the agency of heat. Neither of these views appears satisfactory; to give a merely igneous origin to gneiss is evidently to leave out half the phænomena; to suppose the mineral composition of gneiss the effect of heat operating on a common sandstone will never be allowed by those who have studied the rock as it appears in Zetland, Scotland, or Norway; for in all these places it is clear that the granular minerals have not derived their external figure from concretionary but really from mechanical action, while their exterior structure is truly crystalline. There is however one mineral frequently found crystallized in gneiss and mica schist, viz. garnet; and the history of this mineral leaves no doubt that the rocks in which it lies have been pervaded by a general high temperature, enough to affect such a fusible substance as garnet, but not enough to melt any one of the regular constituents of granite. Here then appears decisive testimony as to the degree of heat which the gneiss and mica schist have experienced. By the operation of this pervading heat the particles of calcareous rocks associated with gneiss and mica schist have undergone a great change: they have been converted to crystallized marble of various colours and qualities.

The arguments above advanced, conclusive as we deem them on the subject of the origin of gneiss generally, are not intended to apply to cases where, by reason of this rock being buried at great depths below the surface, extraordinary effects of heat may be experienced. There, no doubt, the gneiss such as we see it, clearly revealing the history of its formation, may be wholly melted and re-crystallized, so as to lose entirely all traces of its origin. Some such cases may occur, perhaps even we may admit that evidence for them exists in uplifted granitic regions; and thus some of the monuments of the earth's early history may have been lost: but that this cannot be the general rule almost every mountain-chain bears testimony.

In these, the most antient rocks which exhibit to us the combined effects of aqueous and igneous agency, no traces of animal or vegetable life occur, and the conclusion we adopt on the subject is, that few or none of the organized wonders of nature were then in existence, because the physical conditions of the globe within which the existence of animals and plants is limited were not then established. Only one other view of the subject is worthy of notice. According to the hypothesis of the slow reconversion of stratified rocks to granitic compounds, the want of traces of organic forms in the gneiss and mica schist is ascribed to the destroying agency of heat on the calcareous matter of shells, corals, &c., and the carbonaceous substance of plants. That heat will affect such calcareous and carbonaceous compounds in the manner assumed is certain. Perhaps it might be difficult entirely to reject the hypothesis in the case of the primary limestones, whose alteration to crystallized masses may be thought to have wholly destroyed the structure of the shells. Yet as in the limestone of Teesdale, similarly altered by contact with trap rocks, crinoidal stems retain their forms; and as near granite, trap, &c., vegetable remains are recognised, if not in substance, yet at least by their impressions in the shales or grits; and as, finally, among some rocks of the same mineral nature as gneiss and mica schist shells and plants of many sorts appear in the Col du Chardonnet in Dauphiné, the balance of evidence is decidedly against this extreme application of the theory of metamorphism of rocks.*

Upon the whole then the evidence afforded by a careful examination of the oldest strata, in regard to their mineral composition, structure, and absence of organic remains, supports, we will not say establishes, the opinion that these are not only the most antient strata which man can trace, but the oldest products of watery action on the globe, and in a great degree anterior to the origin of organic life.

The general results to which the study of the earliest systems of strata lead are these:—

1. They are the oldest aqueous deposits visible on the crust of the globe, and rest on masses which have received their present aspect from the action of heat.

2. They furnish no proof of the contemporaneous or previous existence of dry land.

3. They are equally destitute of evidence of the contemporaneous or previous existence of plants or animals in the sea.

4. The rocks of this antient system are peculiar in their aspect, and though doubtless derived from disintegrated granite, &c., the constituent particles appear to have undergone much less attrition than those which compose rocks of later date.

5. These rocks are of such great extent as to approach nearer to universal formations than any of later date.

As a general inference, it appears that the circumstances which accompanied the accumulation of these rocks were greatly different from what we now behold, since nowhere on the sea-shores are any such products found, nor can we suppose any thing analogous producible in the bed of the sea, unless where some peculiar agitation of water may hasten the disintegration of granite. The impression was very strong among early writers of the entire want of accordance between the causes of those early strata and those now in action. De Luc (*Lettre* iii.) more reservedly says, 'We have no reason to expect that the operations of those times can be explained by specific analogies with what we observe in the present state of the earth.'

And as one general hypothesis, we may say with the followers of Leibnitz and Fourier, that the proper internal heat of the earth was then only just so much reduced as to allow of a peculiar watery action upon its cooling crystallized masses, but not enough diminished to allow of the conditions within which the existence of organic beings is restricted on the earth.

This hypothesis is independent of the consideration already presented as to the original condensation of the globe, and cannot, we believe, be objected to on the ground of anything known concerning the present state of the interior of the globe; on the contrary, the temperature of the earth augments as we proceed downwards, and this fact, being general, has been shown by Fourier to be inexplicable except as a consequence of a general high temperature now existing in the earth. The planetary spaces round the earth

* We find no vestige of organized bodies in these strata; none therefore existed in the liquid at the time it thus covered the globe.—De Luc, '*Lettre Troisième*,' Sept. 1793.

are colder than any part of its surface (Fourier), and continually abstract heat from it: the globe is continually growing colder though by an insensible rate, must have formerly been hotter, and then must have lost heat more rapidly. The obvious conclusion from the mathematical theory of the heat of the globe, coupled with observations of the temperature below the surface, leads to the adoption, as an inference from facts, of the view above proposed as an hypothesis to explain other facts.

Skiddaw, Cambrian, and Silurian Systems. — These argillaceous rocks of the primary series of strata bear the same relation to the gneiss and mica schist as common clays bear to common sands in modern nature. Some clays are not really more distinct from particular sands in their mineral nature than in the comparative fineness of their constituent particles. In consequence of differences of magnitude and density, particles of clays and sands, which are derived by watery action from the same sea cliff, avalanche, or glacier, are soon separated, carried to unequal distances, and deposited in distant masses. Such, in many cases, is the true origin of the sandstones and shales of the secondary strata, and processes somewhat analogous may perhaps be supposed to have occasioned the remarkable distinctness and even reciprocity of occurrence of the gneiss and mica schist on the one hand and the slaty rocks on the other. It is seldom that both of these types of primary strata abound in the same geographical region, though there is little doubt that both are derived from a granitic basis. In some cases we may best conclude that the materials of the slaty rocks were obtained from the wasted gneiss and mica schist.

Enormously thick as these argillaceous masses are, and extensive as is their geographical distribution, they offer in all countries a general character of aspect which easily arrests the attention and impresses the memory. The colour usually approaches to blue, gray, green, or purple; the texture is usually fine grained, but portions are included not very different from sandstone or conglomerate (grauwacke, or clasmoschist of Conybeare); the structure is laminated and bedded more or less perfectly, and often in addition complicated with regular symmetrical joints; there is another entirely distinct set of such divisional planes called 'cleavage,' traversing the planes of deposition; all these circumstances give to the primary argillaceous rocks a determinate aspect. The limited limestones which interlaminate the mass are seldom so crystalline as those in gneiss and mica schist, and they, as well as the upper and some other parts of the slaty rocks, generally yield organic remains, occasionally in great abundance. These are almost wholly marine (local deposits of land-plants occur), and the animals belong to invertebral tribes—zoophyta, conchifera, crustacea, and augment in number and variety as we pass from the lower to the upper parts of this series of rocks. (ORGANIC REMAINS.)

From a contemplation of the slaty rocks it results:—

1. They not unfrequently rest on the granitic rocks with scarcely any interposition of gneiss or mica schist. (Cornwall, Cumberland, &c.)

2. The proofs which they offer of the existence of dry land are chiefly (or wholly) derived from the organic remains of plants, which are not certainly known among the lower groups, but become tolerably plentiful in the upper parts of the systems.

3. The marine organic remains, shells, corals, crustacea, &c., are very scanty in the older systems, and grow more and more numerous and varied towards the upper strata.

4. The forms and structure of these earliest known fossil races of animals have no extraordinary degree of simplicity, nor are they confined to the lowest or least complicated tribes of invertebrata.

5. The alterations which the rocks have undergone by the action of heat are general, sufficient in most countries to superinduce new structures (slaty cleavage), but not to destroy the traces of organic remains.

A greater resemblance appears among these fine-grained strata to the deposits from modern waters than is found in the earlier rocks: there is less of peculiarity in their laminar and stratified structure; they are more varied; and the alternations of deposits indicate greater variety of natural processes and new conditions, such as the elevation of land, the wasting effects of the atmosphere, and littoral agitation, might occasion.

We may suppose, in order to account for the origin and gradual augmentation of the traces of organic life, that the flow of heat from within the globe to the surface was retarded by the effect of previous cooling, and by the addition of the older sedimentary rocks above the granite; and this is in harmony with the fact that generally the limestones of this system are less crystallized than those which are of older date.

Passage from the Primary to the Secondary Period of Geological Time.—Before the close of the Primary period we find that some limited tracts of land were reared above the waters, so as to nourish the plants which occur in the grauwacke slates of North Devon and the banks of the Rhine (supposing, with the general opinion, that the fossiliferous rocks of Baden, &c., are of this age). The sea had become entirely fit for the residence of marine zoophyta, which abounded so as to constitute reefs and islands; conchifera and gasteropoda forming extensive beds; trilobites of many kinds, and a few traces of fishes. These however are chiefly in the uppermost of the primary series, and would be ranked as transition deposits by all geologists who use that now neglected and somewhat hypothetical term. Yet it is impossible not to be struck by the gradation of character which connects into one long series the granitoid gneiss and the arenaceous Ludlow rocks; the fine-grained gneiss and mica schist with the fissile Snowdon slates and argillaceous Wenlock shale. (See the table of strata, page 138.) In proportion as the deposits on a great scale resemble in character of accumulation those of modern times, so the organic remains appear more and more abundant. Some general change of physical condition, such as perhaps only a change of heat will explain, must evidently be admitted as an hypothesis to connect together this series of phænomena.

After the deposition of the primary strata, the interior forces of heat, no longer operating by a gradual metamorphosis of the previously deposited strata, and by a regulated change of the condition of the sea, appear to have been thrown into a state of critical action, and to have operated on the aqueous deposits of antient date, as at this day the volcanic fires below affect the sedimentary strata accumulated from water above. There is hardly a mountain-range of much importance throughout the world where the effects of great convulsive movements affecting the primary strata cannot be seen: frequently it is ascertained to be the case that these movements happened before the production of any of the secondary rocks; and upon the whole it is evident that the crust of the globe was broken up and disturbed, and the relative geographical distribution of sea and land materially changed by the disturbance. The effects immediately appear: the introduction of a new order of sedimentary deposits, with new geographical relations; the extinction of old and the creation of new groups of organic beings; the commencement of a new act (so to speak) in the great history of the earth.

What relation do the great convulsions here alluded to bear to the movements of a modern earthquake? They are unquestionably due to the same general force, viz. internal heat: a disturbance of the equilibrium of this force is in each case to be admitted—the causes and effects are analogous—but is the modern earthquake due to a physical agency of equal intensity with that which occasioned the antient convulsions of the earth's crust? The uplifting of a mighty range of mountains is a common event, a characteristic occurrence of early geological periods: minute and partial changes of level accompany some modern earthquakes. There is no possibility of explaining the former by the latter, except by taking them as differential quantities, proportioned to the time elapsed; assuming that they always (or on an average) operated in a certain direction; and thus summing an almost infinite series of minute changes to make one decided revolution. This is, and must necessarily be, the view of the advocates of the invariable constancy of the measure of natural agencies.

It is enough, in reply to this speculation, to point to the phænomena which require explanation: they are too mighty in extent, and have too much simplicity and even rarity of character, to allow of the faintest belief that this hypothesis can be true. On a minuter inspection this conviction is deepened by the want of any proof of the occurrence of these thousands of small movements, which must have succeeded one another for the production of the given effect. On the contrary, the enormous and simple displacements,

100 to 4000 feet in a vertical line, and ranging 10 or 100 miles in length; the mutual connexion of such faults; the laws of their relative direction, and other phænomena, utterly reject such an imaginary representation of the measure of primeval igneous agency. A much less improbable view, that the whole movement of a great mountain-chain was accomplished by gradual elevation or depression, operating through long time in one direction, is apparently difficult to reconcile with the narrow and steep ridges produced, the numerous and powerful flexures of thick rocks, the sudden and great fractures, and other characteristic phænomena.

We are therefore driven to believe that the igneous effects of earlier date were far more powerfully and generally excited, at particular epochs, than is now observed to be the case. We may be satisfied that the present aspect of the earth is to be viewed as a period of comparative repose; a period of ordinary and regular action, and frequent compensation among the agencies of nature; and may satisfactorily compare it with the whole or some part of the primary period, but not use it as a measure of the violence which accompanied the transition from one early period to another, and thus, amidst great local or general disorder, restored the equilibrium of the interior and exterior agencies of natural changes. This being supposed, the volcanic excitements of modern date being taken as the terms of a series of effects of partial and local disturbances, and re-establishments of equilibrium, there may yet remain residuary phænomena not so compensated, till some critical combination of events opens a wide access to the interior energies of heat. It is even probable that such do remain. The cavities left by the ejection of lava under the Andes are probably not all compensated by the sinking of the earth in the vicinity, because of the resistance of the coherent crust of rocks above; yet such resistance is limited, and it is at least conceivable that some part of that mighty range may fall in, as did a great portion of Papandayang in Java (1772).

What is here concluded to be true at this day for volcanic regions taken singly, may easily be assumed to be probable for large portions of the earth, when the igneous energy was capable of more general results, because not determined to many local centres of continual or intermitting effect. But we must not leave out of consideration the gradually diminishing force of heat in the globe, whether this be due to a gradual lowering of its proper temperature, or a gradual stilling of calorific chemical processes. The loss of that heat by mere radiation into the cold planetary spaces is a residual phænomenon of infinitesimal value indeed, but of general application to the whole globe, and capable in long time, and independently of local volcanic action, of amounting to a tremendous force. For the heat of the surface of the earth being determined by the heat of the sun and the cold of its planetary path, the exterior crust would contract less than the interior nucleus, and it would depend on various considerations whether at all, and after what intervals, a violent crushing of the crust should happen to relieve the extension of the solid or fluid nucleus. During the earlier periods of refrigeration such critical disruptions may have been frequent; at later times they would occur after longer intervals, with greater violence; and finally, when solidification had gone to a certain depth, there might be no subsequent paroxysm, so long as no external agency came to aid the interior tension.

It may perhaps be worth remarking that the atmosphere of the earlier æras of the world known to geology must be supposed to have transmitted light, much as happens at present, else we should not find the eyes of fossil trilobites constructed as are those of analogous crustacea at this day. (See Dr. Buckland's *Bridgewater Treatise.*)

Secondary Periods of Geology.

On the undulated bed of the sea, round the ranges of primary rocks raised in insulated tracts by great convulsion, secondary strata were formed, sometimes evidently derived from the waste of the primary strata, through the influence of atmospheric agency, or the wearing of the sea on its shores. But a considerable portion of these strata is of purely marine origin; the calcareous strata may be considered as derived from chemical decomposition of the sea-water, separated from it by the vital functions of mollusca and zoophyta, or generated by springs rising in the sea and loaded with carbonate of lime. Of all these modes of formation modern nature offers illustrations, some of them so extensive as to admit of comparison with many of the antient limestone rocks. Others of the secondary rocks appear to have been formed of ejected volcanic matter, ashes and scoriæ, which by diffusion in water have settled into deposits of considerable extent. The total thickness of the secondary rocks is but small when compared with that of the primary groups, nor are they, it is probable, spread over such extensive areas; but in the variety and number of alternations of the different sorts of rocks and in the diversity of their imbedded organic fossils they are altogether superior. There is among them far more of the differences which separate oceanic from littoral deposits; and we see abundant proof that during their aggregation the arrangements of nature were extremely analogous in general features to what we now see, however great and numerous the points of difference may be.

On an attentive consideration of the several systems into which the secondary strata are grouped, viz. (in the order of superposition):—

- Cretaceous System;
- Oolitic System;
- Saliferous or Red Sandstone System; and
- Carboniferous System;

it will be perceived that to each of them belong littoral, marine, and oceanic deposits; sandstones having been chiefly collected amid the agitation of the shores, clays accumulated in quiet bays or gulfs, and limestones aggregated in deeper water; and in each system, each of these classes of deposited rocks contains somewhat characteristic, if not entirely peculiar: sandstones, more or less felspathic, dark bituminous shales, and grey limestones occur in the carboniferous system—red or blue colours belong to the sandstones and clays, and magnesian combinations to the limestones of the next incumbent rocks; light-coloured sands and pale blue clays, with yellowish limestones, mark the oolitic system; and green or ferruginous sands, marly clays, and soft white limestones distinguish the cretaceous rocks.

These distinctions are important, as guiding us to a right general view of the changes of physical conditions which occasioned them. These, it is probable, related chiefly to hydrography, and when we have geological maps complete enough to make the required comparisons as to the extent and distribution of the rocks, it appears possible that the direction of oceanic currents, the lines of antient boundary of land and sea, may become sufficiently known to determine the particular subterranean movements which introduced new conditions and produced new deposits in a given basin of the secondary ocean.

Each of the great systems alluded to is characterised by the plants and animal remains which lie in it: the lepidodendra of the carboniferous sandstones and shales yield place to the voltziæ of the red sandstone, and the cycadeæ of the oolites; the productæ of the carboniferous limestone are never seen among the oolites, which abound with trigoniæ, pholadomyæ, &c., nor in the chalk, from which these forms are absent; ammonites belong to all the systems, but the groups differ in each; belemnites are confined to the two upper; hamites, scaphites, &c. are scarcely met with out of the cretaceous rocks.

These statements might be enormously multiplied [Organic Remains], but enough is said to show that the great features of lithological distinction are accompanied by striking characters of organic remains. These characters, so far as marine life is concerned, may evidently be understood by the same inference of a change of oceanic currents; but the differences of the vegetable world seem to bespeak a general change of the characters of climate.

Reviewing the four systems in succession, we shall find circumstances in each strongly indicative of peculiar combinations of the physical agencies of nature.

Carboniferous System.—To what shall we ascribe the abundance of vegetation which furnished the materials of our coal strata?—an abundance so great as, upon any hypothesis of accumulation on the spot where the plants died, or in the sea to which currents drifted them, appears to have no parallel unless amongst the most umbrageous forests of Tropical America. By the gradual decay and periodical transport of the woods on the Mississippi or Orinoco we may perhaps best understand the accumulation of many beds of coal, alternating with a far greater number of much thicker earthy sediments; but even these aboriginal forests seem unequal to produce such enormous coal deposits as we find in Britain and other

parts of the northern zones of the globe. The circumstances, whatever they were, which favoured this development of vegetable power, were never repeated, at least in these zones, though deposits of a similar nature to the series of coal strata, and likewise containing fossil plants and thin beds of coal, diversify the sand and sandstones of the oolitic, cretaceous, and tertiary æras.

As carbonic acid existing in the atmosphere is the source of the carbonaceous substance of plants, M. Adolphe Brongniart proposes the speculation that it was a great abundance of this ingredient of the atmosphere which favoured vegetation in the carboniferous æra; and he finds support to his view in the fact that during this same period there is almost no trace of the existence of any land animal whatsoever. Now land animals and land plants are, with respect to carbonic acid, in reciprocal relations; the former yielding by respiration what the latter receive by absorption. Carbonic acid is one of the supports of vegetable life; plants of particular sorts may flourish even more abundantly by an addition of it to the air: to animals its excess is poison. To this speculation the constancy of the atmospheric ingredients, as determined by analysis, cannot be objected; for this art, perfected in the 19th century, by no means confirms but rather rejects the notion of such constancy. In how many ways is oxygen fixed and liberated by processes now going on in and upon the land and sea? Who can say if even now its proportions to nitrogen are constant? Is it even proved that any really chemical combination exists between them? Much more should we hesitate to award such constancy to carbonic acid, for this is known to vary in different situations and circumstances. Suppose only 5000 square miles of coal-beds, twenty yards thick, derived from vegetable ruins to be again converted to carbonic acid and distributed over the globe, what would be the result on the proportions of carbonic acid and oxygen in the atmosphere?—what the effect on vegetable and animal life?* More than this quantity of coal has been discovered in Great Britain and Ireland alone in the carboniferous system, and it must have been derived from plants growing on a small extent of the earth's surface. The fossil plants of the coal series have been generally considered by eminent botanists, since the days of Jussieu, as decidedly indicative of a warm climate; the state in which they occur in the earth proves that they have not been drifted far: we are therefore to infer that in latitudes as far north as Moscow, Edinburgh, and Nova Scotia, the land enjoyed near the sea a climate analogous to that now found on the shores of Brazil or in the Isle of France. The same conclusion as to the sea, with rather greater distinctness of evidence, arises from the corals which abound in the carboniferous limestone.

As a general inference we may observe that all the great thickness (2000 or more yards) of the carboniferous system (excepting perhaps part of the old red sandstone series) is clearly derived from wasted lands or sea-coasts, or from a decomposition of the sea-water by vital or chemical agency.

Disruptions of the Carboniferous System.—Whatever was the length of time which elapsed during the accumulation of the carboniferous strata, it appears to have passed with little disturbance of the level of land and sea; for not a single example (we believe) is mentioned of any real unconformity of stratification, in the whole series from the base of the old red sandstone to the uppermost line of the coal strata. The ordinary agencies of the atmosphere and the waves were in full employ, and some traces of volcanic eruptions appear in the trap of Derbyshire and the north of England; but there is not in the accumulation of the often repeated alternation of limestone, sandstone, shale, &c. of the carboniferous system, any thing to require the supposition of greater general convulsions. It was a period not of repose, but of regular and orderly action among the agencies of nature, so far as the parts where now Europe and North America are situated: and the mineral deposits and organic remains are to be compared with existing operations of nature in order to learn the physical condition of the antient land and sea.

After the formation of the carboniferous strata was ended in Europe and America, the long tranquillity of the ocean in these parts was broken by extensive and violent concussion, so that hardly a single square mile of country can anywhere be found which is not full of fractured and contorted strata, in consequence of subterranean movements which mostly preceded the accumulation of the next system of strata.

The relations of land and sea were so greatly changed by these transient convulsions, that the new ridges of land and islands appear to have been variously scattered in the ocean which flowed round the already uplifted Grampian, Scandinavian, and Welsh mountains. An equal or greater extent of land appears to have been elevated in Ireland, but with less violence and concussion; and it is remarkable that some of the greatest faults produced at this epoch were almost wholly unaccompanied by the irruption of any igneous rocks, or any other signs of merely volcanic action (Craven fault, great dyke of Tynedale, South Wales coal field, &c.)

Some more general and more powerful agency than that which we now see in the volcano and the earthquake must be invoked to explain the great and extensive displacement of land and sea which broke, with transient violence, the long quiet of the globe, and gave rise to a new and general change of deposits.

The Red Sandstone System, which is deposited upon and around the broken tracts of the carboniferous system, presents us in some respects with new conclusions, which however seem almost equally to apply to the old red formation. No doubt the sands and clays of this system were collected from wasted land and sea-coasts, and deposited in shallow waters. But whence came the red and greenish colours so characteristic of these strata and the analogous old red formation? The grains of sand which compose much of the rocks are not red, but white rolled quartz sand, surrounded by red peroxide of iron like a varnish. From none of the older rocks could this abundant red pigment be derived so as to stain the whole sea bed for 1000 feet or yards in depth; but we may perhaps appeal to volcanic forces to solve this curious problem. Oxide of iron is one of the most abundant of the substances among volcanic ejections. before the deposition of the red sandstones, enormous and general disruptions of the coal and limestone strata happened, which implies an unusual exertion of igneous agency: the lower parts of the series are full of conglomerates, the natural consequence of the violent displacements of preconsolidated rocks.

Instead of the great quantity of vegetable matter buried in the coal tracts, we have in the principal part of the red sandstones hardly a few insignificant traces; so few in England that scattered fragments are valued in geological reasoning: neither are the marine reliquiæ of the magnesian limestones in the midst of the red rocks at all plentiful, except in a few spots. Even taking the richer German series as a type, the red sandstone rocks must be pronounced singularly deficient in organic fossils; and as, generally speaking, the same deficiency of organic life belongs to the older red sandstone below the mountain limestone, it is at least a plausible supposition that the causes of the red colour and paucity of animal life are somehow closely connected. If we imagine that by reason of the great convulsions which followed the carboniferous æra new currents were brought into the same areas of the ocean, from tracts yielding abundance of new sediments, the extinction of organic life would be the natural consequence, to be followed afterwards by a gradual revival—which is nearly the truth. In the magnesian limestones of this system expire many of the forms of the older carboniferous period, and at higher levels (as in the muschelkalk) we find a strong resemblance of the marine zoophyta shells and crustacea to those of the younger oolitic system. Upon the whole there seems reason to think the new red sandstone system could not have occupied a long time in its formation, compared to other deposits of equal thickness.

Oolitic System.—Into the same European and Asiatic basins which received the red clays, red sands, and magnesian limestones of the last system, subsequent agencies brought blue clays, sands more or less ochraceous, and limestones characterized by an oolitic texture. These deposits are parallel to the old rocks below, and no trace of any change of level in the region where they occur has been noticed in England—perhaps not in Germany. Must we refer to some distant convulsion for an explanation of the change of sediments, and for the equally great change, or rather, sudden development, of organic life, which comes in with the oolitic æra? New and more abundant forms of plants (cycadeæ), with

* The quantity of carbonic acid gas now existing in the atmosphere does not exceed the one-thousandth part. By the addition supposed it would amount to the eight hundred and fiftieth.

many varieties of zoophyta, mollusca, crustacea, fishes, and gigantic reptiles of the land, rivers, and the sea, mark the oolitic rocks, and render them justly comparable, as a system, to the great carboniferous assemblage of strata. Locally indeed the oolitic rocks yield coal among the interpolated grits and shales, just as happens among the rocks interstratified with the older mountain limestone.

The resemblance of the oolitic to the carboniferous limestone tracts is extremely great in general features; and the reason is that both are essentially sea deposits, characterized by calcareous rocks formed in the deep sea, and liable to admixtures of sandstone and shales along the shores. In such situations each is carboniferous. Both are highly rich in oceanic life, but during the formation of the oolitic rocks there is no proof that anywhere such excessive richness of vegetation was renewed on the land as that which yielded the mass of coal plants in an earlier period. The state of the earth during the carboniferous period was compared to that of the tropical parts of America; during the oolitic periods it rather resembles the south-eastern shores of Australia, and indeed special analogies may be traced in both instances. There seems almost no equivalent of this oolitic period on the north American continent, but the carboniferous rocks occur in America, India, and Australia.

Cretaceous System.—The last portion of the series of secondary strata was deposited in the same oceanic basins as the earliest, as far as Europe is concerned, but this is not the case in America. Generally, in Europe the cretaceous rocks have their stratification parallel to that of the oolites, though some unconformity in this respect occurs in Yorkshire and Dorsetshire, and in the south-east of France dislocations affected the oolitic strata before the production of the cretaceous rocks. But these comparatively slight movements of the bed of the sea appear totally insufficient to account for the complete change in the chemical and mineralogical character of the rocks, and the new orders of zoophyta and mollusca which date from the commencement of the cretaceous æra.

Sands coloured green by silicate of iron, white soft limestones with beds or nodules of flint, seem to bespeak an origin from the waste of other lands than those which discharged other sands into the oolitiferous sea, and other modes of chemical or vital action in the sea: yet a scrupulous analysis of the oolitic system shows in its upper part analogies to the cretaceous rocks so strong and so various as to render it probable, if not certain, that the new conditions characteristic of the new system were gradually or partially introduced till they entirely predominated;—for green sands alternate with the uppermost of the oolitic limestones in the Alps; flinty nodules lie in the calcareous grit and Portland oolite, and chalky limestones constitute the great portion of the latter rocks in some situations of England. It is to be regretted that we are so little able to determine upon good evidence what the new conditions influential on the deposits of the cretaceous rocks were; for their effects are very similar along a great range of the Atlantic coast of North America from New Jersey to the Mississippi, and throughout the interior of Europe.

The cretaceous period was not ended in England by dislocations situated in or even near that part of the surface. In Ireland eruptions of basalt of enormous extent cover the chalk, and indicate a crisis of volcanic disturbance. In France Elie de Beaumont refers to the concluding part of the cretaceous period dislocations which range north-north-west in the Jura, and traverse the primary mass of Mont Viso. After the chalk formation was completed in the south of France the Pyrenees were uplifted to a great height, so as to limit the tertiary basins of the south of France; and it is supposed that at the same time the Apennines and Carpathians experienced an upward movement. Conjecture has even joined to these the Alleghanies, but it may be gathered from Professor Rogers's reports on the geology of America (*Brit. Assoc. Reports*) and accordant notices of Featherstonhaugh and other competent geologists, that an earlier date should be allowed to that mountain-range.

Tertiary Periods.

In general no contrast can be more complete than that between the secondary and the tertiary stratified rocks: the former retaining so much uniformity of character, even for enormous distances, as to appear like the effect of one determined sequence of general physical agencies; the latter exhibiting an almost boundless local variety, and relations to the present configuration of land and sea not to be mistaken. The organic bodies of the secondary strata are obviously and completely distinct from those of the modern land and sea; but in the tertiary deposits it is the resemblance between fossil and recent kinds of shells, corals, plants, &c., which first arrests the judgment. In general there is a decided break between the two groups of rocks—a discontinuity which is nowhere completely filled. Yet, besides the pseudo-tertiary or transition chalky rocks of Maestricht and the Pyrenees, and the conchiferous marls of Gosau, we have in England and France above the chalk a prevalence of green and ferruginous sands extremely similar to those below. Perhaps they have been derived from the waste of these older rocks; Mr. Lyell supposes the tertiaries of the London basin to have been formed from the waste of the secondary strata of Kent, Surrey, Sussex, and Hampshire.

With the tertiary system came into existence (if we may trust the negative evidence which the earlier strata present) many races of quadrupeds, some birds, reptiles, and fishes, extremely analogous, though for the most part specifically distinct from the modern denizens of land and water; thousands of corals, shells, crustacea, &c., which present with living races quite as great analogy as obtains between the tribes of the Atlantic and the Pacific oceans of our day: the general features of land and sea as they now exist begin to appear, and there can be no doubt that in a philosophical study of the revolution of the globe the tertiary æra of geology cannot be properly separated from the existing system of nature.

Yet during the deposition of these rocks the relations of land and sea were greatly altered in Europe by the rising of the Pyrenees beyond the height they reached after the cretaceous æra, and by the uplifting of the Alps from the Mediterranean towards Mont Blanc. In England we may believe the upward movement of the southern counties connected with the Hampshire axis of elevation and the Isle of Wight convulsion, was ended before the close of the tertiary period. The eastern range of the Alps from Mont Blanc to Vienna is of later date, and may be viewed as the most marked phænomenon of elevation which accompanied or preceded the dispersion of erratic rocks in Europe

§ 7. Present Aspect of the Globe.

Physical Geography.—According to every view of geological causes and effects, the present aspect of our planet is the result of all its previous changes; these changes cannot be completely understood if we leave out of consideration the daily variations which occur in the condition of the earth, nor can the operation of existing agencies be completely represented to our minds without calling in aid the inferences derived from a study of earlier phænomena.

One of the most important things ascertained by geological investigation is the certainty that the operations by which stratified rocks were formed in the sea-bed, and the igneous rocks uplifted from below, were repeated nearly in the same succession over most parts of the globe. Some of the formations are very extensive: in all countries the lowest strata are of the character of gneiss, mica schist, slate-rocks, &c. These primary strata may almost be termed universal: the organic forms which they contain, though few, are very similar or exactly identical, over enormous areas; and there can be no doubt that during the deposition of these antient rocks the earth enjoyed a uniformity of conditions over its surface never since repeated. There is no proof that land existed anywhere in the earlier part of this period—no probability that any part of our continents or islands then stood above the water. At the close of the primary period the effect of elevatory forces was manifested by the existence of some narrow ridges and peaks of rocks, corresponding to some of our present mountain-tracts, as the Grampian and Cumbrian mountains, and of others now vanished, which nourished the forests and herbs whose destruction has yielded coal.

Through the secondary period this elevation of land proceeded gradually, or by intermitting action, till at the close of that period some of the principal features of European geography were visible; the ocean was contracted and divided into many basins and gulfs, some of which remain, as the Adriatic, English Channel, German Sea, &c., while others, as the Vale of the Danube, Sea of the Rhine, &c. have been dried by further elevation.

The same elevatory action, continued through the tertiary æras, completed the geographical features of Europe, and though we cannot trace so minutely in other parts of the world the contemporaneous changes, enough is known to assure us that the same causes have, within the same general limits of time, produced, in all quarters where dry land appears, the same phænomena.

Elevation of Land.—In the preceding pages we have spoken of the elevation of land from the sea as a thing perfectly well understood, and admitted as a basis of reasoning. It is so admitted by geologists of every shade of opinion who wish to explain effects by real causes. Yet, as some persons who read this may desire to see the process of argument by which, if doubted, it might be proved, we shall present a short sketch of the reasons which have produced on this important point a general agreement among geologists.

1. In existing nature the combined influence of the exterior and interior causes of change cannot materially affect the level of the sea (as estimated by the mean radius of its surface). Within sensible limits the sea-level is now permanent. This is sufficiently apparent by the reasoning in § 4 of this treatise. 2. The land now above the waters was formerly below them, and could only have been laid bare by the elevation of parts of the sea-bed, or by the abstraction of the ocean to other regions, either through depression of its bed or through a displacement of the axis of rotation, or by a universal diminution of the quantity of water on the globe, or by a change of the oceanic level through great alterations of temperature at the surface, or through the mass of the globe.

In examining these possible modes of desiccation of land, geology must have recourse to collateral science. The two last hypotheses, viz. of a change of oceanic level, without change of external form or axis of rotation, are insufficient for the purpose. Sound reasoning rejects the supposition of an indefinite waste of oceanic waters for miles in depth, because the position of our planet in space yields no escape for the water; nor is there any ground for believing that the quantity fixed in mineral compounds since the date of the earliest strata is of much importance. A general change of temperature of the globe would certainly alter the relative level of land and water, because their rates of expansion and contraction are unequal. Between the boiling heat, 212°, and what is probably below the mean temperature of the actual seas, 40°, the contraction of the water would be about ·042 of the whole quantity. The land certainly would contract less, and thus by a general cooling of the globe the ocean-level would relatively sink. To put the case to extreme, we shall suppose the contraction of the land = 0, the area of the water to remain unchanged, and the mean depth of the sea ten miles; the reduction of level of the ocean would be $\frac{42}{100}$ of a mile = 739 yards. Now as all the conditions of the problem have been taken in extreme, as the deepest part of the sea probably does not exceed ten miles, as one quarter of the spherical surface is land, and the area of the sea must diminish as its level sinks, it is very obvious that the greatest possible change of oceanic level from this cause could only go to one, two, or three hundred yards at most; and therefore it is impossible by such means to explain the desiccation of land from 1000 to 10,000 or 20,000 feet high.

Moreover, during this cooling of the land and sea the whole globe would contract; and from this cause the mean radius of the ocean diminish and its mean depth augment, so as to reduce still more the possible extent of land that could be drained by its change of dimensions.

The attraction of the ocean to other regions would lay dry parts of its bed; and if astronomical science permitted to geologists to change at their pleasure the position of the axis of rotation of the earth, few difficulties need stop the career of speculation; but the earth is a spheroid of revolution, and if the attraction of the heavenly bodies in the various positions which it takes with regard to them does not disturb its axis of figure, neither can it be thought that the volcanic fever of its surface can so alter the interior densities as to cause any sensible change in this respect.

But that the bed of the sea may have sunk, that other continents than ours may have fallen below their antient level, may be assumed as readily as the rising of the existing land; but with this restriction, that the sinking of the bed of the sea requires to be far greater than the rising of the land, because three-quarters of the globe are covered by water, and thus a small difficulty is overcome by introducing a greater.

Finally, on turning to the phænomena connected with mountain chains, it is perfectly certain from the position of the strata – often vertical or contorted in the sides of chains, highly inclined near them, and gently sloping at greater distances—that these rocks have been displaced by an elevating force acting from below. The direction of the force, the geological time of its occurrence, its sudden or gradually accumulated intensity, and many other characteristic circumstances, can be determined; and upon the whole no doubt remains that elevating movements have raised the land, and there is no reason to deny that depressing movements may have sunk the bed of the sea. Our limits prevent the farther development of this subject.

Outline of Land and Sea.—Througnout all the globe the outlines of land and sea depend principally on the disposition of mountain-chains and groups, which in every instance yet known are certainly shown to have been raised by mechanical agency, generally with a degree of violence so great as to require the supposition of great and general excitement of the subterranean forces of heat. America, for instance, derives its form from the chains of the Andes and Rocky mountains, the littoral range of Brazil, the Alleghanies, &c.; mountains probably of very unequal antiquity. The Ghauts define the western side of India, as the Atlas marks the north-western border of Africa; the Pyrenees and Sierras give the form of Spain; the Cornish, Welsh, Cumbrian, Lammermuir and Grampian ranges explain the figure of England and Scotland.

Frequently however this dependence of the form of the existing land upon the ranges of mountains is disguised by the extent of comparatively plain country which separates the mountains from the sea. Thus all the eastern half of England might seem to have its form independent of the narrow ridges of the western mountains; and it is but a vague relation which links the Baltic, the Black Sea, and the Caspian to the Harz, Saxon, Carpathian, Caucasian, and Uralian chains. In these and many other cases it is necessary to admit that the general level of the sea has subsided, or that large tracts of land have been raised gradually, or by successive movements around the mountains, which in earlier times were uplifted by more violent effects. The diagrams, *figs.* 2, and 3, p. 137, illustrate the fact of the general slope of the English strata from the western mountains; but this cannot be explained by the violent elevation of these mountains, for this happened principally before the deposition of the coal strata. A large area round these mountains has since been gained from the sea by more gradual changes of level.

Similar phænomena present themselves in detached areas all over the world; but in very unequal degrees, and with unequal differences of level above the ocean, even in neighbouring tracts. It appears therefore more probable that particular regions have risen round the same points and lines which once experienced a violent upward movement. There is no reason to deny that the ocean-level may have been somewhat lowered by the subsidence of a part of its bed; but it has been already shown that no reasonable (perhaps no possible) sinking of the ocean-bed could explain the phænomena of the desiccation of even the flatter parts of the land.

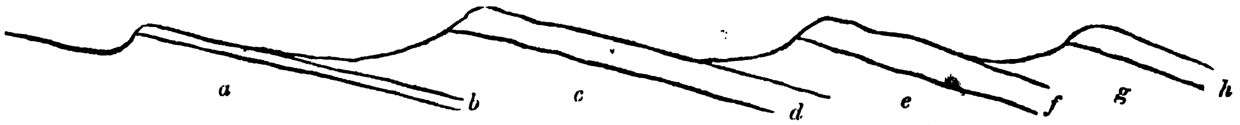
Interior aspect of a Country.—The interior features of every country in like manner depend upon recognised geological agencies. The unequal elevation of mountain-ranges above the sea is a phænomenon which will be found of great importance in geological theory. It appears to be true, at least in Europe, that the most elevated chains of mountains are those whose elevation was not ended (if, indeed, it be yet ended) until the tertiary or later epochs. Thus the Alps, which bear on some of their heights (Diablerets), caps of tertiary strata, ascend to 15,660 feet above the sea: the Pyrenees, whose principal elevation appears to have followed soon after the chalk, to 11,270; the Carpathians, nearly of the same date, to 8675 feet; while in the Harz the older mountains (Brocken) rise to 3739; in Wales (Snowdon) to 3675; in the Grampians (Ben Nevis) to 4350. The highest point of Norway Schnee-Haten is more than 8000 feet above the sea, but there can be no doubt that violent as well as gradual upward movements affected the Scandinavian ridges to a late geological æra.

sed in this manner by violent or gradual movements f the sea, the dry land has since been subjected to e by atmospheric action; and there is no doubt of the th, that to different sorts of rock belong some differences aspect, some characteristic scenery. The forms of the hills and valleys are not the same in the gneiss and mica schist of the Grampians; the clay-slate ranges of Wales; the limestone of Derbyshire; the oolites of Gloucestershire; the chalk of Wiltshire: even single rocks and waterfalls have distinctive characters, and the whole aspect of a country changes with its geological structure. It thus appears that the nature and structure of the rocks, their elevation above the sea, and the manner in which they attained it, and the intensity and duration of the atmospheric agencies which have since affected them, are the elements which determine in every instance the physical aspect of a country.

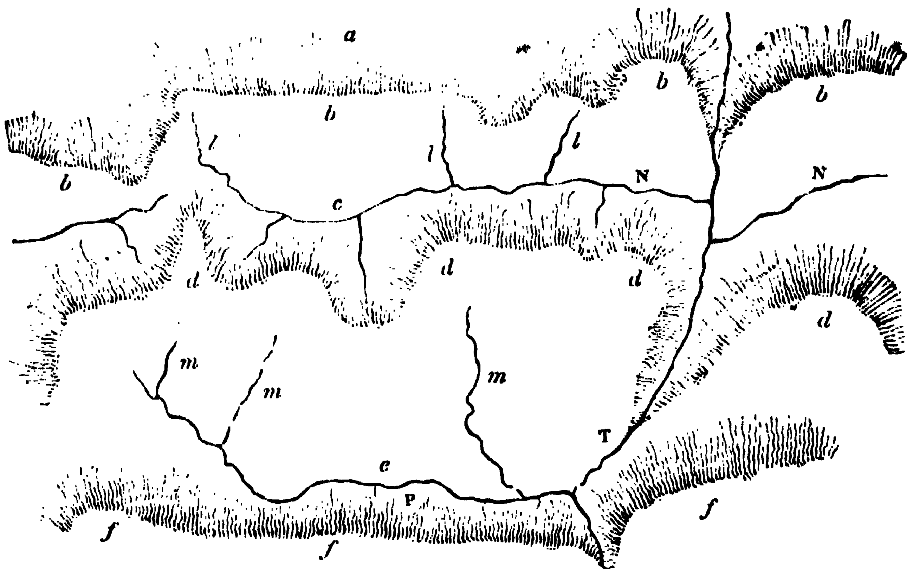
Valleys.—No question in geological theory has been the subject of so much debate, with so little of correct reasoning, as that of the origin of valleys. By Dr. Hutton it was contended that atmospheric agency and running waters had excavated valleys; by De Luc the subsidence of the crust of the earth was invoked; Omalius D'Halloy introduced the consideration of dislocations on the line of the valley; and Dr. Buckland appealed to the overwhelming force of a general flood. None of these views is entirely wrong; each contains partial truth; and the complicated problem of the inequalities of the surface of the earth can be solved by combining them. This solution may be attempted elsewhere we can here present only some of the principal data.

By violent elevation from the sea, rocks, of whatever nature or structure, must have been variously broken and fissured. It is conceivable that some of these fissures might descend below the level of the water. During the elevation some considerable effect on the forms of the ridges and hollows would be produced by the agitated water, but the smaller modifications which they have experienced must be ascribed to atmospheric agency. In these few words we have the history of the rough hills, abrupt valleys, and deep lakes which belong to mountain chains like the Grampians, Alps, and Pyrenees.

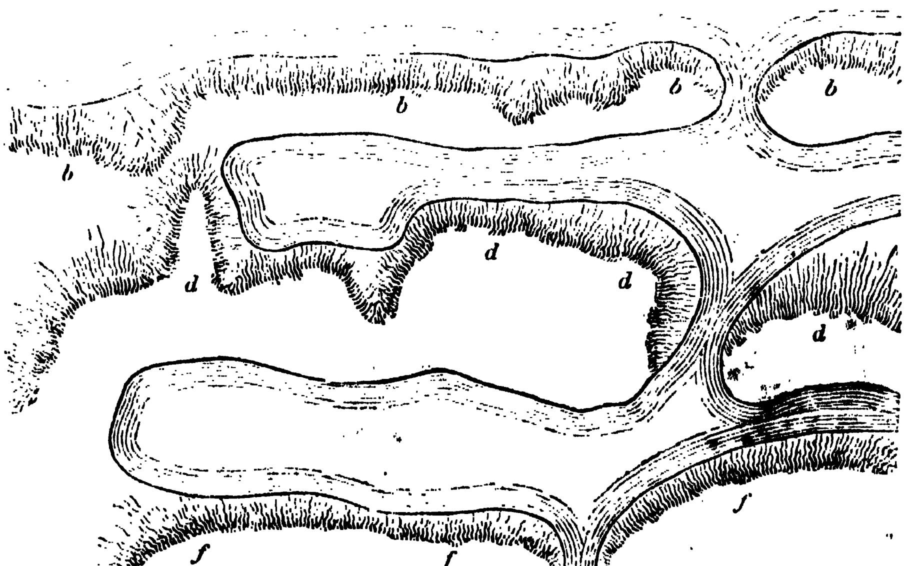
By gradual risings or interrupted lifts of the bed of the sea, other phænomena would arise; the action of the sea upon the rocks, successively brought within the sphere of its littoral movements, would concur with the form of preexisting land, and the entrance of its drainage waters, in extending the old and producing new valleys. The greater number of these extended or new valleys would be directed at right angles to the axis of elevation in progress, and therefore, on the dry land, the greater number of valleys originating in these circumstances will be found to run with the dip of the strata. How exactly this agrees with



No. 4. *a*, Red marl; *b*, lias limestone; *c*, lias clays; *d*, lower oolite formation; *e*, Oxford clay; *f*, middle oolite formation; *g*, Kimmeridge clay; *h*, upper oolite.



No. 5. *a, b, c, d, e, f*, have the same meaning as in the figure 4; *l l l*, *m m m* valleys which descend with the slope of the strata, here supposed to dip south; N N, and P, longitudinal valleys, or such as run parallel to the outcrop of the strata; T, a transverse valley, uniting the longitudinal ones.



No. 6. The letters have the same signification as in Nos. 4 and 5.

the general character of the drainage channels of the secondary strata of England above the red sandstone requires only to be mentioned; and it has been already shown that in all the south-eastern parts of England where these strata occur there is sufficient evidence that the elevation of these rocks was due to gradual and long-continued, not violent and transitory movements. While such gradual movements occurred, and strata of unequal hardness and different structure (as limestone and clay, or sandstone, in diagram No. 4), were brought within the range of littoral action, these would be unequally affected by the tidal and other currents; the softer parts would be worn away, the harder remain; and thus the red marl would be wasted parallel to the coast-line, or to a certain depth in the water, below the cap of lias limestone; the lias clays would yield beneath the crown of lower oolite; the Oxford clay be excavated below the middle oolite; and the Kimmeridge clay form a vale between the middle and upper oolites.

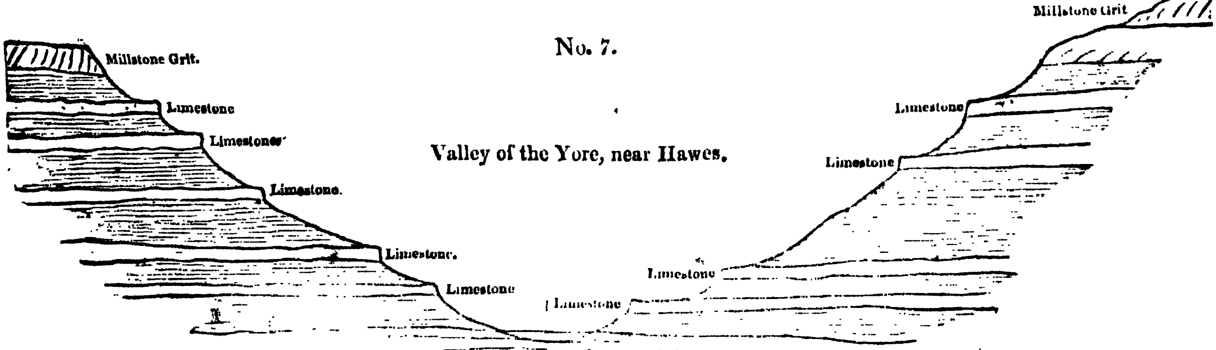
The exact conformity of this with the appearance in nature is well known. The general character of the actual drainage, as Dr. Smith has often and elegantly explained, may be represented in diagram No. 5, where *l l l* and *m m m* are valleys descending on the slopes of the strata, N N and P valleys formed in softer strata parallel to the coast; T a transverse valley uniting the others.

In the next diagram (No. 6) the same country is represented as rising out of the sea, which penetrates by the transverse valley across the ridges of rocky hills, and flows round them up the vales of clay; its waves wasting the clays under the cliffs, and causing the top to fall, exactly on the same principle that waterfalls at this day, by wasting the argillaceous basis, break down the crowning limestone beds throughout all the north of England.

The Giesbach, on the lake of Brienz, compared with the Staubbach; Hardrow Force in Yorkshire, or Ashgill Force in Cumberland, contrasted with the Fall of Lodore, near Keswick, are in this respect very instructive; nor should the cases be neglected where, as on the coast near Scarborough, Robinhood's Bay, and Whitby, the sea now flows among the lias and oolitic rocks, and wastes their argillaceous parts on a small scale, almost exactly as in the above explanation it is supposed to have wasted the similar but thicker clays, when the whole system was rising above the waves. Pleasing illustrations of this kind of action occur in the Medlock at Manchester, the Greta near Ingleton, the sea-coast near Heysham, Sunderland, Berwick, &c. In the

No. 7.

Valley of the Yore, near Hawes.



Isle of Wight the fresh-water limestones and clays, and the various beds of the plastic clay series about Culver, offer abundance of curious examples.

Forms of Hills.—The same mode of action is traced the forms of mountains and hills which are composed of strata of unequal resisting power; as mountain limestone and shale in the Yorkshire dales, oolite and clay in the Gloucestershire Hills, Normandy, or the Jura mountains.

The above diagram (No. 7) represents a cross-section of Wensley Dale, which for a great part of its length exhibits, wherever a considerable rock of limestone comes to the surface, a decided projection and terrace on the hill sid , and below every such rock a slope formed in the alternating shales and thin sandstones.

How much of this appearance is due to atmospheric action and rain since the river Yore has been running in its present bed, and how much to the influence of water bathing the hill-breasts at higher levels, is not easy to determine; but the correspondence of the strata on the opposite sides is such as to leave no doubt that all the vast space of the valley has been really excavated out of continuous strata; and the survey of the whole line of this and other rivers appears to refute the opinion that the existing drainage waters have carried off much of the detritus.

To conclude this brief notice of the origin of the principal inequalities on the earth's surface, it may be proper to remark that the view here given of the excavation of valleys, at the time of the rising of rocks from the sea, explains the otherwise unintelligible phænomenon of dry valleys in chalk, oolite, and other calcareous strata, which wind and unite like the branches of a river, and have slopes and features such as to prove their origin from moving water, but contain no trace of a stream, no mark of a spring, and often no alluvial sediment.

It appears also necessary to remark that, independent of the facts here stated, there must be some importance attached to the effects likely to be produced by the violent agencies, whatever they were, to which the origin of diluvial phænomena is ascribed. The essential thing however in this case being a relative change of level of land and sea, the result of the watery agitation could only be to modify in a greater or less degree the more considerable effects of previous agencies of longer duration. Gravel heaped in particular places conceals some of the earlier slopes of land, and covers with irregular hillocks an original sea-plain, but the great features of the country remain comparatively unaffected by these transient disturbances.

Life on the Globe.—Geology enables us to behold, in the present varied and complicated arrangement of land and water, the result of many and repeated actions of causes which are not yet extinct, but continually occupied in similar operations, in different situations, and under different circumstances. The land which has been raised from the sea by internal expansion seems to be slowly wasted away by the action of water, and again restored to the deep. But new land is formed by these ruins, and volcanic fires are yet competent to raise or depress the bed of the sea.

The land is not all of the same antiquity; some regions must have been covered by trees, perhaps or rather certainly traversed by quadrupeds, before the substance of others was laid on the bed of the sea. Since life was developed on the globe, if geology has rightly interpreted the monuments of nature, there has never been any considerable period during which the land or sea was wholly deprived of organic beings; but as the condition of the globe changed, the forms of life were altered, old races perished, new creations were awakened, the sum of animal and vegetable existence was continually augmented, and the variety of their forms and habits continually multiplied, as the ditions of land and sea were diversified, until man was added to the wonders of creation, and historic time began.

If then, through all past geological time, organic life has changed its aspect as physical conditions varied—if the present physical aspect of the globe is derived from previous physical revolutions, must we look on the present system of organic being, adapted to the present physical conditions, as similarly derived by corresponding revolutions from earlier systems of life, corresponding to earlier states of the land and sea?

If the physical aspect of the globe is now changing, does its organic enrichment vary likewise; or is the relation of organic life and physical condition one of coincidence merely—one of those adjustments independent in its nature, though associated in time and situation, which offer the most convincing proof of continual superintendence of the divine lawgiver of nature?

Though we cannot here enter at large on a subject which requires the details which are found under another head

[Organic Remains], there are points of too general importance, in reasoning on the present condition of the globe, to be wholly omitted: 1. The relation of form and structure between the living and extinct worlds of life; 2. The distribution of the existing forms of life, in reference to the geographical features and geological history of different parts of the globe.

The relation of living to extinct races of plants and animals is various. In point of number, the recent is perhaps 100 times as considerable as the fossil Flora, and though this is in some degree owing to the circumstance that land-plants, insects, &c., must necessarily be comparatively rare in marine strata, yet the vast number of individual plants accumulated in coal tracts does not appear to justify a very high estimate of the variety of specific forms of plants in early periods. The same is true f the marine races of shells, crustacea, fishes, &c.; for both the total number of species, and the relative number to a given thickness of strata, augment from the early towards the later formations, and are greatest of all in the tertiary strata, which in character of organic life most nearly resemble the modern productions of nature.

On comparing the living with the vanished tribes of plants and animals, we are struck with the fact that hardly one species of the fossil kingdom is so peculiar in its structure that nothing at all like it is now in existence. Recent analogies of extinct forms are continually and unexpectedly presented to us by the attentive voyagers who now explore the most remote and unknown regions of the land and sea, and continually revealed to us by the discoveries of comparative anatomy, which detects in common forms traces of analogies to extinct creations formerly altogether unsuspected. Thus the belemnite, the trilobite, the ichthyosaurus, are reduced to their proper station among mollusca, crustacea, and reptilia, and the whole extinct and living world of nature becomes united into one general system.

But this indubitable affinity between the plants and animals now living and those which adorned the world in earlier ages does not require us to adopt the speculations of Linnæus, Lamarck, and St. Hilaire, that specific forms of plants and animals are no further permanent than the circumstances which surround them: that as these change those vary; that the immense variety of organic structure may have been derived from a few primitive types—the living gavial from the fossil teleosaurus, the living cuttle from the fossil beleinnosepia, the living from the fossil equiseta. This doctrine, plausible as it seems, and flattering as it is to that propensity in man to derive everything from a beginning of which his own senses may give some notion, must be rejected for three reasons:—

1. In existing plants and animals the experience of mankind, for two or three thousand years, has shown no essential change.

2. There is no proof, drawn from examination of fossil reliquiæ, of this assumed change from one species to another, much less from one genus to another. On the contrary, it is a very striking truth, illustrated in almost every group of fossils, that while the same species retains through many deposits of different age its essential characteristics, new ones come into view in many of these strata, not by a gradual change, but by a sudden development.

3. The destruction of old races and the introduction of new appear in many cases to have been sudden and complete, at least locally.

In considering the distribution of existing forms of life, with reference to the geographical features and geological history of different parts of the globe, we cannot avoid being struck with the fact that each species, each genus, and often each family, of plants and animals, is especially abundant in and often exclusively confined to particular parts of the land or sea, even among those animals whose powers of locomotion are the greatest. Among fishes, birds, and swift quadrupeds, this attachment to locality is scarcely less remarkable than among plants, zoophytes, and mollusca, which have no means of diffusing their races, except what winds and currents give. It has therefore become an admitted truth in the philosophy of natural history, that there are certain regions of the land and tracts of the sea for which particular groups of plants and animals were specially created, and to which for the most part their existence is still confined.

The living species of plants and animals which most nearly resemble fossil races are variously distributed over the globe. Tree ferns, gigantic equisetaceæ, and other plants illustrative of the flora of the carboniferous period, may be found in Brazil, the Indian Islands, and Australia; coniferous plants occur in colder latitudes, or at greater heights in the tropics, as well as in the lias; cycadaceæ occur in South Africa and Australia, and tropical America, as well as in the oolites. The recent trigonia and cerithium giganteum are found on the Australian shore; pholadomya was washed on the island of Tortuga; and cucullæa belongs to the Indian Ocean. Lingula is found in the Moluccas; but terebratula in all seas: the nearest living form to the old fossil crocodiles inhabits the Ganges; while the bony pike, whose scales resemble those of megalichthys, lives in Lake Ontario.

Perhaps we ought to conclude from these facts that some particular regions of the globe still retain, in their climates and other circumstances, decided analogies to those earlier conditions which were once more general on the globe. In this point of view the comparison of recent and fossil animals and plants deserves to be much more prosecuted than it has been.

§ 8. Geological Time.

There is perhaps no more difficult problem in geology than the determination of the length of time which has elapsed during the formation of the whole or any definite part of the crust of the earth. Time, as measured by generations of men, fails to carry us back to remote geological epochs; man is but a recent visitor of the globe; compared even to the secondary strata his date is of yesterday, for *all* the existing forms of life cease with the lower tertiary rocks, only small proportions of them occur in the middle of that series, and traces of men have nowhere been seen in any but the most modern parts of the stratified masses of the globe. If then the history of the human race does not commence till after the deposition of at least the greater part of the tertiary strata, by what rules shall we attempt to compare the few thousand years of his existence with the earlier periods of the history of the globe?

In a vague sense, nothing appears more obvious than the conclusion universally admitted among geologists, that the earth is of vast antiquity, yet nothing more eludes the grasp of reasoning than the seemingly easy task of computing its age. The rocks are indeed full of monuments of time, 'rudera longinqui sensim præterlapsi ævi,' but we have not yet learned fully to decipher them.

When we behold thousands of strata piled on one another in a regular series, each distinct by some peculiarity from the others; when we find among these the original products of chemical action (as limestone), the slow sediments from gentle motion (clays), rough sand and pebbles implying greater agitation; how can we refuse to admit that long time elapsed during the often repeated change of chemical and mechanical agencies of water over the same portions of the bed of the sea?

When among these strata we observe the remains of plants and animals, various in their kinds, regular in their distribution, so as to prove that at successive times the same part of the sea nourished successive races of animals, and buried in its sediment distinct races of plants, where in modern nature is it conceivable that such repetitions of change, in all the ranks of creation, could take place except by the aid of almost immeasurable time?

Descending to minuter inquiries, we find some particular strata composed of fragments derived from a more antient rock, which after being deposited in water, was indurated, raised to the surface, wasted by drainage, and again collected in rolled fragments on the bed of another sea. The trees which are imbedded in certain rocks (coal-measures, lias, Portland oolite, &c.), are often known by their rings of growth to be some decads of years old, and in particular cases (Dirt-bed of the Isle of Portland) it is supposed that their whole life passed between the formation of two beds of stone.

Every country affords examples of certain fossil shells confined to even a thin layer of shale, sandstone, limestone, or ironstone, and in some instances (near Leeds and Bradford) the youngest embryo goniatite and the oldest full-grown shell (how much must we regret the want of means to state the full age of our recent mollusca!) are found in one bed of six or twelve inches' thickness, in that alone, and apparently in the place of their quiet existence, so as to indicate that the lifetime of that goniatite (G Listeri) was consumed during the accretion of one calcare-

ous bed, which is about $\frac{1}{5000}$th part of the thickness of the coal-measures whose history it enriches.

If again, among those strata produced by watery action we find alternations of volcanic rocks, and learn that at particular epochs in the series of deposits mountains were raised from the sea, land clothed with forests was submerged, and the physical geography of particular regions entirely changed, we see clearly that such repeated revolutions of nature agree with the history of the organic creations in refuting the narrow views of those who would limit the age of the world to the short annals of mankind.

But how are we to proceed further, so as to clothe with a more philosophical character these almost poetic notions of the immensity of past geological periods? Three orders of effects are in this respect important:—

1. The deposition of stratified rocks. 2. The changes of organic life on the land and in the sea. 3. The displacements of land and changes of physical geography.

The phænomena of stratification are at this day repeated, and on a very considerable scale, in most parts of the world. Where great rivers sweep earthy materials and vegetable reliquiæ to the sea, (Mississippi, Amazon, Rhine, Po, &c.,) littoral aggregations take place and new land is formed; tides and currents throw up sand-banks, or disperse the finer sediment far from shore over the quiet bed of the ocean. From the growth of new land on the Adriatic and Egyptian coasts, by the action of the Po and the Nile, some notion may be formed of the great quantity of sediment annually transported by rivers to the sea, and both reason and experience show that the materials are there accumulated in the same manner as the antient strata were.

But are they now accumulated with the same, with greater, or less rapidity? If equal deposits are now formed in equal times, the calculation of the age of the visible crust of the earth is as easy as it would be philosophically useless; but to assume this principle is to nullify the conclusion from it. Unless it can be shown, *à priori*, that atmospheric influence must have been constant through all past geological time, the assumption will not be accepte. This cannot be satisfactorily shown, for the external excitants on which the atmospheric actions depend have been proved to contain variable elements (§§ 3, 4). No certain conclusion then can be rested on the comparison of the mere thickness of the stratified rocks, as to the lapse of time, unless there can be found an independent scale of time which may help to interpret the other.

2. Such a scale of time is perhaps contained in the series of organic beings imbedded in the earth. These belong to many successive systems of life, which may be compared with the existing forms of nature, and could we establish from history any rate of change in organic life, any per centage of species destroyed, or created in a given series o. years, some considerable steps might be laid for further advance. But two or three thousand years appear to have made no change on quadrupeds, birds, reptiles, fishes, shells, or conspicuous plants. As far as can be known by study of old writers on natural history, sculptured monuments, coins, and mummies, no change of external form or internal structure has been experienced since the earliest historical æra; the loss of a very few species is all that can be safely admitted; and no proof is offered of a single newly-created form, though the distribution of the different groups of plants and animals has been varied by sea-currents carrying seeds and ova, and altered by man, who has learned to conquer by obeying nature.

As far therefore as the more obvious and characteristic forms of animals and plants can be admitted to yield satisfactory evidence, the period of two thousand years since the days of Aristotle would be insufficient even as a unit of measure by which to estimate the intervals of geological time which elapsed during the deposition of strata. This conclusion is strengthened by some and weakened by other considerations. It is weakened by the circumstance that the changes of organic life appear to have been sudden; it is fortified and illustrated in a powerful degree by comparing existing nature with the tertiary æra, for thus the five or more thousand shells of this day appear to be joined to an equal number of others, into one long series of definite organic forms, which, since the date of the chalk, have admitted new and lost old species continually. Whether these new species, in any particular basin of strata, were parts of one or more new creations there, or, as may perhaps be thought probable, transferred from ther centres of oceanic life, is quite unimportant for the rgument as to time. The effects resemble those noticed mong the older strata, the causes must be assumed to be correspondingly similar, and the times must be in some degree proportionate. Uniting therefore the tertiary and modern æras into one great geological period, we may compare the unknown quantity of time which it includes with other equally unknown and older intervals in the history of the globe, corresponding to similarly complete series of organic forms. This comparison is facilitated by the remarkable fact of the almost total distinctness of the organic beings of successive geological periods. Had the shells of successive systems of strata been gradually changed by substitution, we should have been compelled to compare not systems but formations, or even individual strata; and the conclusions might have become irremediably obscure.

The systems to be compared are:—Tertiary, Cretaceous, Oolitic, Saliferous, Carboniferous, Fossiliferous, Primary.

The following table, extracted from Professor Phillips's Guide to Geology,' 3rd edition, gives the proportionate thickness and number of organic forms of these systems:—

Strata.	General thickness.	Number of species of organic remains to 100 ft. thickness.
Tertiary	2000 ft.	141
Cretaceous	1100	70·7
Oolitic	2500	45·6
Saliferous	2000	8·2
Carboniferous	10,000	4·7
Primary	20,000	2·0

Hence it is very obvious that any conclusions as to time, drawn from the mere number of species which were developed and destroyed with any system of strata, will be totally opposed to others based on the observed thickness of the strata. The inferences are obvious and important; the numerical relations of organic life to the amount of stratified deposits are variable; one cannot be used as a measure of the other; the variety and abundance of organic life has been augmenting from the primary to the tertiary æras, or the deposition of strata was in the early ages of the world fifty times as rapid as in the tertiary period. This latter conclusion can never be allowed, since the fossiliferous primaries show clearly their origin from land-floods and littoral currents, and these depend on influences which cannot be supposed to have varied in any such proportion.

It thus appears that neither the numbers of organic fossils nor the thicknesses of strata afford a perfectly satisfactory scale by which to measure past geological time; but whichever of them be preferred, the age of the world cannot be estimated at less than several times the whole tertiary period, and compared with this the historical portion of time, which dates from the birth of man, contracts to a point.

By uniting the two considerations above stated, it will appear certain that the rate of organic development has been augmented, and probable that the rapidity of sedimentary deposition diminished since the primary æra; and it is no slight argument in favour of the hypothesis of a gradually cooling globe, that both these phænomena are natural consequences of it,—for that the greater influence of the earth's proper heat in the earlier epochs would favour the mechanical but limit the vital activity of nature seems to require no proof.

If however independent proof were required of this change of ratio among the agencies of nature, we must appeal to a third order of phænomena most certainly characteristic of disturbances of the equilibrium of the earth's proper temperature: the fractures, contortions, and other marks of the violent elevation and depression of the crust of the globe.

From what has been already stated it is very clear that the principal phænomena of this description occurred specially at particular intervals during the long periods of geology; for example, after the primary period, after the carboniferous æra, before and after the accumulation of the cretaceous strata, after many of the tertiaries were produced. Now on comparing the amount of disturbance effected at these epochs respectively we are unable to perceive that the efficient causes have diminished in force; for the elevation of the Alps in the tertiary period is apparently quite as conspicuous a phænomenon as can be found among older geological monuments. M. Elie de Beaumont, to whose speculation as to the geographical characters of subterranean movements allusion has already been made, supposes that as many as twelve distinct epochs of mountain-elevation may be recognised. The following is a brief sum-

mary of the classification which best suits the geology of England:—

Geological Period.	Effects noted.	Localities.
1. After the deposition of the Skiddaw Rocks.	Beds of argillaceous conglomerates.	Derwent Water.
2. During the deposition of the Snowdon Rocks.	Porphyry, greenstone, and trappean conglomerates.	Under Helvellyn, in Snowdon, &c.
*3. After all the primary strata were deposited.	Principal elevations of primary rocks.	Grampians, Lammermuirs, mountains of Cumberland and Wales.
Conglomerate rocks follow in the old red sandstone.		
*4. After the deposition of the coal strata.	Immense faults, anticlinal axes, &c.	The great faults of Tynedale, the Penine chain, Craven, Derbyshire, Flintshire, South Wales, and generally of the coal districts.
Conglomerates follow in the red sandstone.		
5. After the oolitic period.	Unconformity of stratification between oolite and chalk system.	Yorkshire, Dorsetshire.
*6. After the London clay.	Anticlinal axes and vertical strata.	Isle of Wight, Axis of the Wealden.

At the three epochs marked by stars, the most considerable movements and greatest changes in physical geography appear to have been produced. Such changes also occurred about the same epochs on the continent of Europe: the most universal of the phænomena seem to be the two earlier ones; but it is almost impossible in any case to prove that the occurrence of convulsions was synchronous at distant points. Since then we can neither affirm anything with respect to the change of force of the subterranean monuments at different geological epochs, nor can ascertain, except by reference to the phænomena of stratification and organic life, whether they occurred more frequently in one period than another, it is impossible to draw from the evidence of these disruptions any certain conclusion either as to the change of the earth's proper heat or the extent of geological time. If indeed the actual effects of earthquakes were to be placed against the mighty wall of the Penine fault, the vertical beds of the Isle of Wight, or the concealed dislocation of the coal-fields of Valenciennes, there would be no doubt of the decay of natural agencies; but this is not allowable, for the great dislocations alluded to are to be viewed as phænomena of a short interval of violent movements between long periods of ordinary action such as now obtains on the globe.

It may be supposed that the number of these cases of very great and extensive disturbance is in proportion to the time elapsed; but as none such has occurred within the reach of history for at least 4000 years, we see how very antient is the earth; and further, we have no data for accurately computing in numbers the vast periods which have elapsed in producing the stratified crust changing many times its vegetable and animal races. On the whole it appears that the day is not arrived for theory to trust itself with the attempt to assign definite values to the symbols of duration which remain in the earth. Long, undoubtedly, perhaps as long as the periods which the study of planetary motions has revealed, must be the whole range of geological time; but until we know at this day what is the average rate of deposition of sediment in the sea, or the usual age of marine mollusca, until we can determine the numerical or structural relations between organic forms and physical conditions, or can convert the irregular effects of volcanic fires into a calculable series of changes of temperature, there is little hope that the invitation of the Royal Society, to assign the antiquity of the crust of the earth, will be accepted by prudent and competent geologists.

§ 9. Economical Applications of Geological Science.

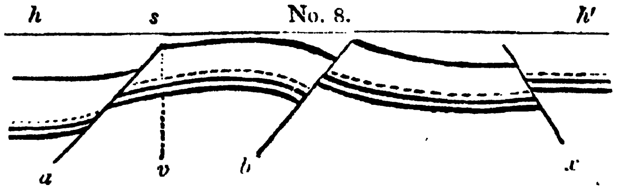
Practice, Mr. Whewell tells us, has ever been the nurse of theory: art has ever been the mother of science, the comely and busy mother of a daughter of far higher and serener beauty. But the benefits are reciprocal; geology, at least, is capable of well repaying the large debt which it owes to the experience of the miner, the engineer, and the agriculturist, and indeed some of its truths are already largely productive of public benefit.

Situation of Collieries.—There is hardly a district in this island where the reasoning of geology has not checked extravagant expenditure in search of coal or metallic ores where such are not to be found, and conquered the credulity of ignorance ever ready to listen to the delusive and almost superstitious notions of merely working colliers and miners. The false and deceitful promise of finding good coal by going deeper, will not often again lure the landed gentry and respectable companies to such adventures as sinking for coal in the oolites of Oxford the sandstones of Sussex, or the silurians of Radnorshire. But it is not merely by preventing foolish and wasteful expenditure, in search of imaginary treasures, that geology has aided the mining interest: it is within our memory that the eminent practical men of the great northern coal-fields doubted or denied even the existence of coal under the magnesian limestone. Yet now the Hetton colliery, and (in consequence of Mr. Wm. Smith's geological report in 1822) the South Hetton colliery, send enormous quantities of excellent coal to the London market from beneath the dreaded magnesian limestone. The almost universal prejudice of colliers that 'Red rock cuts off coal,' has been vanquished in Lancashire, Staffordshire, and Somersetshire, and reasons have been given by Conybeare and others for believing that under the red rocks of the midland counties great tracts of coal remain for the public advantage and the triumph of geology. (*Phil. Mag. and Annals.*)

Very recently, Lord Dartmouth, guided by geological reasoning, in opposition to the views of the local colliers, sunk a trial pit for coal near Birmingham, and found it below red sandstone rocks. It was faulty near the pit bottom, but this will not probably prevent the establishment of a valuable colliery, nor discourage further attempts in the vicinity.

Coal-working.—In the practical department of coal-working, geology can as yet render little aid, because the experience of the coal districts has never yet been turned into science. The subject of the 'faults' ('troubles,' as they are often and justly called), from which no coal-field is exempt, and which by their effects on subterranean drainage, and the disarrangement of the subterranean works, their influence on the quality of the coal, and other circumstances, are of the highest importance to the collier, is yet almost wholly unknown as a branch of science. One general fact known concerning them (the correspondence of the dip of the fault to the depression of the strata), may be illustrated in the subjoined diagram taken from Phillips's *Guide to Geology*, third edition, plate iv., fig. 13.

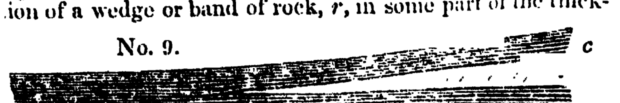
No. 8.



In this figure the faults *a*, *b*, and *x*, decline variously from the horizon *h h'*; and they are most frequently found to dip or decline under that portion of the divided strata which is relatively depressed, as *a* and *b*, not as *x*, which represents a rare and exceptional case. By the sides of faults the strata are often slightly or considerably bent, sometimes in the direction tending to unite their disrupted parts, as *a*; sometimes in the contrary way, as *b*. In the former case they are said to 'rise to an upthrow and dip to a downthrow;' in the latter they 'rise to a downthrow, and dip to an upthrow.' If these circumstances were carefully recorded by surveyors of collieries, science might eventually combine the detached facts into general laws, show their dependence on other conditions, and thus put an instrument of discovery into the hands of practical men.

It is a common thing to find valuable coal-beds at first injured, and ultimately rendered worthless, by the interposition of a wedge or band of rock, *r*, in some part of the thick-

No. 9.



ness of this coal; thus the High Main Coal of Newcastle is split, and in a particular direction ruined by the 'Heworth Band.' The upper part of the Great Staffordshire coal-beds goes off in 'the Flying Reed;' and the ten-feet bed of Barnsley in Yorkshire divides into almost unknown parts. If the details of colliery working were completely recorded (as for the public good they ought always to be), the law of these phænomena would perhaps be traced, so as to answer the

anxious questions which such intrusive bands suggest to coal proprietors.

The variations of quality in coal, whether of different beds in the same district (a common case), or of the same beds in different districts (as in South Wales, where good furnace coal is found in the east, and anthracitic coal abounds in the west), are not now known in a scientific form; and therefore science can give no help to practice. Nothing but the union of the parties interested in coal-working can furnish the data necessary for the establishment of general rules; and it is gratifying to find that one great district has set an example of such union, in the Geological Society of the West Riding of Yorkshire.

Situation of Mines, &c.—The beneficial results which mining operations have derived from geology are in proportion to the degree in which the experience of miners has been reduced to the form of science. On the subject of the situation of metallic treasures, already enough is known to show that the occurrence of mineral veins is a circumstance depending on conditions which are more or less ascertainable. For example, there is not, and perhaps has never been, in the British Isles, a single mine of any metal worked in any stratum more recent than the magnesian limestone; it is a general truth that rich veins of lead, copper, tin, &c., abound only in and near to districts which have been greatly shaken by subterranean movement; in Derbyshire, Alston Moor, Flintshire, and, in particular tracts, especially Cornwall and Devon, it is very apparent that near the great masses of granitic rocks the veins are most richly filled. The same facts are almost equally true on the continent of Europe, and in other parts of the world, though, occasionally, as in the Pyrenees, Auvergne, &c., the presence of igneous rocks may cause the exhibition of mineral veins in strata more recent than any of those which in England yield metallic ores.

In all cases where new mining ground is to be attempted, rules such as those above noticed are valuable; but even in districts partially known, or long worked, many problems occur which time and combined registration of phænomena observed might easily solve. These geological problems, as to the relation between the contents of a vein and the nature of the neighbouring rock, the occurrence of certain cross-veins, the depth of the workings, &c., usually present themselves to the practical miner under the general question of the probability of the vein being productive, and though the mining experience of 2000 years has been found insufficient to answer it, there appears no reason to doubt that it is capable of solution by the progress of geology. It is known that in a country of limestone, gritstone, and shale, equally broken by the same fissures, the former is generally most productive of lead (Alston Moor): that certain porphyritic rocks in Cornwall and Saxony appear directly influential on the deposits of particular metals; that argentiferous lead ore is more frequent in primary than in secondary strata; salts of lead more plentiful in the upper parts of veins (Lead Hills, Caldbeck Fells): but the precise nature of the connexion of the phænomena is yet a desideratum, and it will be long ere the dim and wavering light of experience can be replaced by the steady beams of the torch of science. (Von Duchen's *Handbuch*: Taylor's *Report to the British Association.*) [MINERAL VEIN.]

Engineering.—In planning the lines of railways, canals, or common roads, the engineer will often be benefited by the records of geological surveys. In looking at the geological map of England, for example, it must be evident to any one acquainted with the geographical characters of the different formations, that no canal can be made from London to the western or north-western counties without a tunnel or summit level on the chalk hills (as at the Kennet and Avon, between Wilton and Devizes, and on the Grand Junction, at Tring). The oolitic range of hills, with its basis of lias, presents a similar and parallel obstacle, conquered by tunnels on the Thames and Severn at Shepperton, the Oxford canal at Claydon, the Grand Junction at Braunston and Blisworth.

Since then these and other ranges of hills compel the formation of summit levels and tunnels, it is of importance that the whole of a country should be known to the engineer, as to its mineral structure as well as its elevation, in order that the situation of these may be properly fixed. It was inconvenient to make the Thames and Severn tunnel at its present level, often much above the level of the spring which is called the source of the Thames, and in the thirsty oolitic rocks; for thus the cost of maintaining the supply of water by puddling the canal, and engines for pumping, has been found very oppressive. Tunnels and summit levels for canals should certainly be made in argillaceous rocks, and geological investigations will often point out situations where, from particular displacements of the rocks, this is practicable, even in a range of hills so continuous and so calcareous as the chalk or the oolites.

The same rules do not apply to railroads, which on the contrary may often be beneficially carried through dry rocky hills which would absorb all the water of a canal.

In the execution of the works of canals and railroads, a good geological map would often be found more serviceable as a guide to the engineer than a great number of borings, unless these were placed in situations corresponding to the variations of the strata, which such a map would indicate.

Architecture.—In some favoured countries the labours of the sculptor and the architect are scarcely injured by exposure to the atmosphere for 2000 years; while in our damp and changeable climate, even the interiors of cathedrals show, by the decay of the marbles and the destruction of the stone walls the necessity for an architect to study the durability of his materials. It is remarkable that the Romans were more prudent or more fortunate in their choice of stone for buildings in Bath and York than their successors have been. The reliques in the Institution at Bath abundantly prove that the rag beds of the oolite are more durable than the finer and handsomer freestone, which the enterprise of Allen first introduced to common use. The magnesian limestone in the Roman walls of York is in far better condition of preservation than most of that which is of only half the age in the face of the cathedral.

The Saxons, in the north of England, used the coarse and durable millstone grit, which on the brows of the high mountains of Derbyshire and Yorkshire stands conspicuous for its bold defiance to the elements. In choosing from any given rock the parts which are most fitted for permanent edifices, the examination of nature is perhaps more instructive than even a study of buildings. Not every sort of granite resists the carbonic acid and moisture of the air; but while the rolled blocks from Shap-fell retain, after thousands of years' exposure on the surface, their surfaces of attrition, the granitic top of Castle Abhol, in Arran, is so rotten that it may be easily beaten to fragments by a hammer. The millstone grit of Brimham is almost wasted away over a hundred acres, while that of Agra Crags appears to be more cap[able] of withstanding the same agencies; and the druidic... of Boroughbridge have stood the storms of 2000 years, with little more injury than a few rain-channels which scarcely reach the ground.

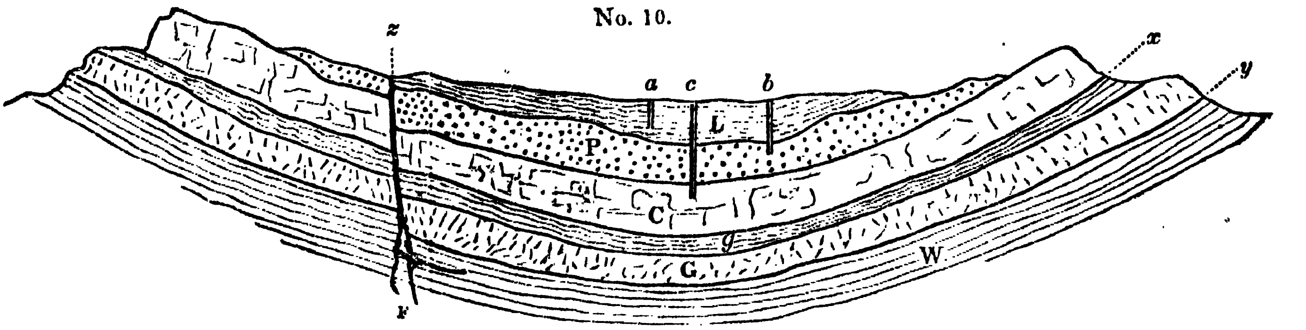
Supply of Water, Draining, &c.—To the agriculturist geology has rendered some services, and probably may in future be appealed to for further aid. Lister's proposal for the construction of a map of soils was only partially executed, after a century, in some of the county reports made to the Board of Agriculture. The principal use, as it appears to us, of such a map (and this is in fact supplied by the maps of strata), is to aid the statistics of agriculture by furnishing a basis for comparing the agricultural practices on similar and dissimilar soils.

But geological science will appear more intimately connected with agricultural improvements if we consider it as the basis of all sound knowledge of springs and the subterranean distribution of water. The rain which falls from the heavens upon all soils and rocks indifferently runs off the clays, but sinks into the limestones, sandstones, and other rocks, whose open joints act like so many hidden reservoirs; owing to the complicated intercommunication of the fissures, these reservoirs are slowly filled and slowly emptied; both the supply from rain and the discharge from springs may and generally do go on together, and the jointed rocks may be viewed as equalizing the supply and expenditure.

But below the level of the springs thus formed a great body of water exists in the deeper parts of the earth, and in fact fills the whole space left by fissures in the rocks, unless where, as in diag. No. 10, there be a fault which breaks the continuity of the communications along the rocks. At .... surface there will be generally one or more springs (z) along the line of such a fault, F.

In sinking deep pits it is generally found that argillaceous strata are quite dry within; for example, in the diagram

No. 10.



a, b, c, Wells. L, London clay. P, plastic clay and sands. C, chalk. *g*, gault. G, lower green sand. W, wealden. *x, y, z*, springs; the last at a fault, F.

above referred to, the well *a*, supposed to be sunk in the London clay, yields no water; but the other strata, alternating with the clays, yield water in greater or less quantity, and of quality corresponding to the nature of the rock. Thus the well *b*, sunk down to the sands, lignites, &c. of the plastic clay, yields some water, not always of good quality; but when the well, as *c*, is made to reach to and penetrate the chalk, a great body of good water commonly rises from that rock. The illustrations of this and other phænomena relating to subterranean drainage already given under the head Artesian Well, may be consulted for further information.

To drain land is to intercept the natural springs: this can never be done upon good principles unless the geological structure of the district be known. When porous rocks alternate with strata impervious to water, the springs will commonly issue at several points on the surface line of junction of the strata, as at *x* and *y* in diag. No. 10; and, by making a deep drain along the line of junction, Dr. Smith has often accomplished the complete desiccation of wet lands in the oolitic districts of England, which had been in vain guttered in all directions by the usual hollow drains.

The same principle applies, but not with the same ease or success, to the draining of districts where gravel and clay are much intermingled. The gravel acts as a porous rock, but its irregular distribution renders the operation of deep draining costly and less effectual.

From the same principles it follows that springs may be regulated, and the subterranean reservoirs employed to store up water in winter, when it is little wanted, for the purpose of supplying the demand in summer. This has actually been done by Dr. W. Smith, who opened, in the sandstone rocks near Scarborough, a subterranean reservoir on the site of a little spring, closed it with a dam, and regulated the discharge for the benefit of the town. (*Phil. Mag.*, 1827.) See for further details the article Springs.

GEO'METER, a person who is skilled in geometry; but the term derives its meaning from the time when geometry was by very much the most important branch of mathematics, and now it generally means mathematician. For instance, the French (who make considerable use of the term) call Laplace *un géomètre*, though his writings are exclusively algebraical. The term must then be understood to signify simply mathematician.

GEOMETRICAL. Of this term as opposed to algebraical or arithmetical, nothing need be said; but the peculiar conventions of geometry oppose it most frequently to the term *mechanical*. Every construction which can be made by the ruler and compasses; that is, which demands no points except such as can be found by the intersections of straight lines and circles, is *geometrical*: every construction which requires any other curve, or which tacitly requires such a motion of a straight line or circle as would generate any other curve, is *mechanical*. The reason is that it pleased the Greeks to use these terms as distinctive of the things which can and cannot be done by the straight line and circle only: a real and important distinction with an unfortunate name. For though names, when clearly understood, are of little consequence, yet this convention of geometry has caused many to waste their time and misapply their talents. A man for instance not well versed in mathematics, hearing that a *geometrical* quadrature of the circle has long been sought, and never been found, sets his invention to work, easily discovers a (mechanical) method of proceeding, and imagines that everything is geometrical which employs lines, solids, &c., in space.

The conic sections were not considered by the Greeks as geometrical instruments. Several writers speak as though the contrary had been the case; but it is certain that the solution by Menechmus of the problem of two mean proportionals, which employs the parabola, was not considered by Eutocius (who records it) as more geometrical than the others which he gives.

GEOMETRICAL PROPORTION, PROGRESSION, &c. [Proportion; Progression; &c.]

GEOMETRY (γεωμετρία, *geométria*, or land-measurement), the science which investigates the relations existing between parts of space, whether linear, superficial, or solid. But at the same time, the most common meaning of the word implies that the investigation is to take place under restrictions as to the instruments which may be employed. Of this we shall see more when we come to the Geometry of the Greeks; in the meanwhile, geometry may be generally defined as the science of space.

As geometry is in all probability the most antient subject to which actual demonstration was applied, we may thus account for the permanent association which has always existed between the idea of this science and that of rigorous deduction. To reason geometrically is a synonyme for to reason strictly: but abandoning this particular view of geometry to the article Logic, &c., we shall devote the present article principally to such an imperfect sketch of the early progress of the science as its meagre history, combined with the narrowness of our limits, will allow.

There is a *stock history* of the rise of geometry, supported by the names of Strabo, Diodorus, and Proclus, namely, that the Egyptians, having their landmarks yearly destroyed by the rise of the Nile, were obliged to invent an art of land-surveying in order to preserve the memory of the bounds of property; out of which art geometry arose. This story, combined with another attributing the science directly to the gods, forms the first light which we have on the subject, and both in one are worthily sung by the poet who figures at the head of an obsolete English course of mathematics—

> 'To teach weak mortals property to scan,
> Down came geometry and formed a plan.'

There is no proof whatever that the Egyptians were more of geometers than of astronomers [Astronomy], and the supposition that the rise of the Nile obliged the builders of the pyramids to make new landmarks once a year, requires at least contemporary evidence to make it history. At the same time, the question of the actual origin of geometry is a very difficult one, and any conclusion can only be of very moderate probability.

Among the Chinese, the Jesuit missionaries found very little knowledge of the properties of space: a few rules for mensuration and the famous property of the right-angled triangle being all that they could ascertain. Of all the books which Gaubil could find professing to be written before B.C. 206 there is only one which contains anything immediately connected with geometry. From this writing (called Tcheou-pey) it is not very certain whether the Chinese possessed the property of the right-angled triangle generally, or only one particular case; namely, when the sides are as 3, 4, and 5: and nothing appears which directly or indirectly resembles demonstration. The Hindoos produce a much larger body of knowledge, but of uncertain date. The works of Brahmegupta and Bhascara, of the seventh and twelfth centuries of the Christian æra (according to Colebrooke), contain a system of arithmetical mensuration which is certainly older than the compilers mentioned, and in which the property of the right-angled triangle is made to produce a considerable number of results; for instance, the method of finding the area of a triangle of which the three sides are given. By a figure

drawn on the margin of some manuscripts, it appears that a demonstration of the property in question had been obtained. [HYPOTHENUSE.] The circumference of the circle is given as bearing to the diameter the proportion of 3927 to 1250 by the later writer; being exactly that of 3·1416 to 1. Brahmegupta takes the proportion of the square root of 10 to 1, or 3·16 to 1. The superior correctness of the later writer could not have arisen from any intermediate communication with Europe, since the true ratio was not known so near as 3·1416 till after the twelfth century: and the Persians (as appears by the work of Mohammed ben Musa) had adopted this ratio from the Hindus, before the discovery of an equally exact ratio in Europe. We shall enter into more detail on this subject in the article VIGA GANITA, merely observing that though no date can be fixed to the commencement of geometry in India, yet the certainty which we now have that algebra and the decimal arithmetic have come from that quarter, the recorded visits of the earlier Greek philosophers to Hindustan (though we allow weight rather to the tendency to suppose that philosophers visited India, than to the strength of the evidence that they actually did so), together with the very striking proofs of originality which abound in the writings of that country, make it essential to consider the claim of the Hindus, or of their predecessors, to the invention of geometry. That is, waiving the question whether they were Hindus who invented decimal arithmetic and algebra, we advance that the people which first taught those branches of science is very likely to have been the first which taught geometry; and again, seeing that we certainly obtained the former two either from or at least through India, we think it highly probable that the earliest European geometry also came either from or through the same country.

Of the Babylonian and of the Egyptian geometry we have no remains whatever, though each nation has been often said to have invented the science. In reference to the authorities mentioned above in favour of the Egyptians, to whom we may add Diogenes Laertius, &c., we may say that no one of the writers who tells the story in question is known as a geometer except Proclus, the latest of them all; and as if to give the assertion the character of an hypothesis, this last writer also adds that the Phenicians, on account of the wants of their commerce, became the inventors of arithmetic. In the Jewish writings there is no trace of any knowledge of geometry. So that allowing the Greeks to have received the merest rudiments either from Egypt or India, or any other country, it is impossible to name any quarter from which we can with a shadow of probability imagine them to have received a deductive system, to ever so small an extent. That their geometry, or any of it, came *direct* from India, is a supposition of some difficulty: those who brought it could hardly have failed to bring with it the decimal notation of arithmetic. That Pythagoras travelled into India, is (according to Stanley) only the assertion of Apuleius and Clemens Alexandrinus, though rendered probable by several of his tenets.

Thales (600 B.C.) and Pythagoras (540 B.C.) founded the earliest schools of geometry. The latter is said to have sacrificed a hecatomb when he discovered the property of the hypothenuse before alluded to; and this silly story is repeated whenever the early history of geometry is given. A large collection of miscellanies might easily be made from the works of writers who were not themselves acquainted with geometry; but, rejecting such authorities, we shall content ourselves with citing Pappus and Proclus, both geometers, who, living in the fourth and fifth centuries after Christ, had abundant opportunities of hearing the stories to which we allude, and of receiving or rejecting them.

According to Proclus (book ii. ch. 4, *Comm. in Eucl.*) Pythagoras was the first who gave geometry the form of a science, after whom came Anaxagoras, Œnopides, Hippocrates of Chios (who invented the well known quadrature of the lunules), and Theodorus of Cyrene. Plato was the next great advancer of the science, with whom were contemporary Leodamas, Archytas, and Theætetus, of Thasus, Tarentum, and Athens. After Laodamas came Neoclides, whose disciple Leo made many discoveries, added to the accuracy of the elements, and gave a method of deciding upon the possibility or impossibility of a problem. After Leo came Eudoxus, the friend of Plato, who generalized various results which came from the school of the latter. Amyclas, another friend of Plato, and the brothers Menæchmus and Dinostratus made geometry more perfect. Theudius wrote excellent elements, and generalized various theorems. Cyzicinus of Athens cultivated other parts of mathematics, but particularly geometry. Hermotimus enlarged the results of Eudoxus and Theætetus, and wrote on *loci*. Next is mentioned Philippus, and after him Euclid, 'who was not much younger than those mentioned, and who put together elements, and arranged many things of Eudoxus, and gave unanswerable demonstrations of many things which had been loosely demonstrated before him.' He lived under the first Ptolemy, by whom he was asked for an easy method of learning geometry, to which he made the celebrated answer, that there was no royal road. He was younger than the time of Plato, and older than Eratosthenes and Archimedes. He was of the Platonic sect.

Such is, very nearly entire, the account which Proclus gives of the rise of geometry in Greece.

Before the time of Euclid demonstration had been introduced, about the time, perhaps by the instrumentality, of Pythagoras; pure geometry had been restricted to the right line and circle, but by whom is not at all known; the geometrical analysis, and the study of the conic sections, as also the consideration of the problems of the duplication of the cube, the finding of two mean proportionals, and the trisection of the angle, had been cultivated by the school of Plato; the quadrature of a certain circular space had been attained, and the general problem suggested and attempted by Hippocrates and others; a curve of double curvature had been imagined and used by Archytas; writings existed both on the elements, and on conic sections, loci, and detached subjects. It is in this part of the present article that we have judged it best to introduce what would otherwise have formed the article EUCLID OF ALEXANDRIA. A writer who has given his own name to a science cannot be treated of in any other place than its history.

It is not known where Euclid was born. He opened a school of mathematics at Alexandria, in the reign of Ptolemy the son of Lagus (323—284 B.C.), from which school came Eratosthenes, Archimedes, Apollonius, Ptolemy, the Theons, &c. &c., so that from and after Euclid the history of the school of Alexandria is that of Greek geometry. He was, according to Pappus, of a mild and gentle temper, particularly towards those who studied the mathematical sciences: but Pappus is too late an authority for the personal demeanor of Euclid, and moreover may have been incited to praise him for the purpose of depreciating Apollonius, of whom he is then speaking, and against whom he several times expresses himself. Besides the Elements, Euclid wrote, or is supposed to have written, the following works:—

1. Σύγγραμμα Ψευδαρίων, a treatise on Fallacies, preparatory to geometrical reasoning. This book, mentioned by Proclus, does not now exist, and there is no Greek work of which we so much regret the loss. Had it survived, mathematical students would not have been thrown directly upon the Elements, without any previous exercise in reasoning. [MATHEMATICS.]

2. Four books of Conic Sections, afterwards amplified and appropriated by Apollonius, who added four others. So says Pappus, as already mentioned in APOLLONIUS PERGÆUS. That Euclid did not write these books, appears to us more than probable from the silence of Proclus the Platonist, who, eulogizing Euclid the Platonist, and stating that he wrote on the regular solids (a part of geometry cultivated by the Platonists), being led thereto by Platonism, never mentions his writing on the still more Platonic subject of the conic sections. But that Aristæus had written on the subject is known, and that Euclid taught it cannot be doubted, any more than that Apollonius, like other writers, prefixed to his own discoveries all that he judged fit out of what was previously known on the subject.

3. Περὶ Διαιρέσεων, on Divisions. This work is mentioned by Proclus in two words. John Dee imagined the book of Mohammed of Bagdad (which is annexed to the English edition of Euclid hereinafter cited) on the division of surfaces to be that of Euclid now under consideration; but there seems to be no ground for this notion. The Latin of this work (from the Arabic) is given at the end of Gregory's Euclid, together with a fragment 'De Levi et Ponderoso,' attributed, without any foundation, to Euclid.

4. Περὶ πορισμάτων, on Porisms, in three books. This is mentioned both by Pappus and Proclus, the former of whom gives the enunciations of various propositions in it, but the text is so corrupt that they can hardly be understood. On this singular question, see the article PORISM.

5. Τόπων πρὸς ἐπιφάνειαν, Locorum ad Superficiem: which we cannot translate. It is mentioned by Pappus, but has not come down to us.

The preceding works are either lost or doubtful; those which follow all exist, and are contained in Gregory's edition, in the order inverse to that in which they are here mentioned.

6. Ὀπτικὰ καὶ κατοπτρικά, on Optics and Catoptrics. These books are attributed to Euclid by Proclus, and by Marinus in the preface to the Data; or rather books on these subjects. Savile, Gregory, and others doubt that the books which have come down to us are those of Euclid, and Gregory gives his reasons in the preface, which are—that Pappus, though he demonstrates propositions in optics and also in astronomy, and mentions the Phænomena of Euclid with reference to the latter, does not mention the Optics with reference to the former—and that there are many errors in the works in question, such as it is not likely Euclid would have made. Proceeding on the supposition that rays of light are carried *from the eye to the object*, the first of these books demonstrates some relations of apparent magnitude, and shows how to measure an unknown height by the well-known law of reflected light. In the second an imperfect theory of convex and concave mirrors is given.

7. Φαινόμενα, on Astronomical Appearances, mentioned by Pappus, and Philoponus (cited by Gregory). It contains a geometrical doctrine of the sphere, and though probably much corrupted by time, is undoubtedly Euclid's.

8. Κατατομὴ κανόνος and εἰσαγωγὴ ἁρμονική, the Division of the Scale and Introduction to Harmony. Proclus mentions that Euclid wrote on harmony, but the first of these treatises is a distinct geometrical refutation of the principles laid down in the second, which renders it unlikely that Euclid should have written both. The second treatise is Aristoxenian [Aristoxenus], while the first proceeds on principles of which Gregory states he never found a vestige in any other writer who was reputed anterior to Ptolemy (to whom he attributes it). The second treatise is not geometrical, but is purely a description of the system mentioned, and as this treatise is not alluded to by Ptolemy nor by any previous writer on the subject, it is very probable that Euclid did not write it.

9. Δεδομένα, a Book of Data. This is the most valuable specimen which we have left of the rudiments of the geometrical analysis of the Greeks. Before a result can be found, it should be known whether the given hypotheses are sufficient to determine it. The application of algebra settles both points; that is, ascertains whether one or more definite results can be determined, and determines them. But in geometry it is possible to propose a question which is really indeterminate, and in a determinate form, while at the same time the methods of geometry which give one answer may not give the means of ascertaining whether the answer thus obtained is the only one. Thus the two following questions seem equally to require one specific answer, to one not versed in geometry:—

Given, the area of a parallelogram, and the ratio of its sides; required, the lengths of those sides: and

Given, the area of a parallelogram, the ratio of its sides and one of its angles; required, the lengths of the sides.

The first question admits of an infinite number of answers, and the second of only one; or, in the language of Euclid, if the area, ratio of sides, and an angle of a parallelogram be given, the sides themselves are given. The same process by which it may be shown that they are given serves to find them; so that the Data of Euclid may be looked upon as a collection of geometrical problems, in which the attention of the reader is directed more to the question of the sufficiency of the hypothesis to produce one result, and one only, than to the method of obtaining the result.

A preface to this book was written by one Marinus, the disciple and successor of Proclus, explaining at tedious length the distinction of 'given' and 'not given.'

10. Στοιχεῖα, the Elements (of Geometry). For a long time writers hardly considered it necessary to state whose elements they referred to, since a certain book of the elements always signified that book of Euclid: and it was customary in England to call each book *an* element: thus in Billingsley's old translation the sixth book is called *the sixth element*.

The reason why the Elements have maintained their ground is not their extreme precision in the statement of what they demand [Axiom]; for it frequently happens that a result is appealed to as self-evident, which is not to be found in the expressed axioms. Neither does their fame arise from their never assuming what might be proved; for in the very definitions we find it asserted that the diameter of a circle bisects the figure, which might be readily proved from the axioms. Neither is it the complete freedom from redundancy, nor the perfection of the arrangement; for book i. prop. 4, which is very much out of place, considering that it is never wanted in the first book, is, in point of fact, proved again (though not expressed) in prop. 19. Neither is it the manner in which our ideas of magnitude are rendered complete, as well as definite: for instance, book iii. prop. 20, is incomplete with Euclid's definition and use of the term angle; nor with that term as used by him can the 21st proposition of that book be fully demonstrated without the help of the subsequent 22nd. In fact, the Elements abound in defects, which, if we may so speak, are clearly seen by the light of their excellencies: the high standard of accuracy which they inculcate in general, the positive and explicit statement which they make upon all real and important assumptions, the natural character of the arrangement, the complete and perfect absence of false conclusion or fallacious reasoning, and the judicious choice of the demonstrations, considered with reference to the wants of the beginner, are the causes of the universal celebrity which this book has enjoyed. We shall, in the article Mathematics, give our reasons for advocating the continuance of Euclid as a book of instruction, and shall now describe the contents of the Elements.

There are thirteen books certainly written by Euclid, and two more (the fourteenth and fifteenth) which are supposed to have been added by Hypsicles of Alexandria (about 170 A.D.).

Book i. lays down the definitions and postulates required in the establishment of plane geometry, a few definitions being prefixed also to ii., iii., iv., and vi. It then treats of such properties of straight lines and triangles as do not require any particular consideration of the properties of the circle nor of proportion. It contains the celebrated proposition of Pythagoras.

From this book it appears that Euclid lays down, as all the instrumental aid permitted in geometry, the description of a right line of indefinite length, the indefinite continuation of such a right line, and the description of a circle with a given centre, the circumference of which is to pass through a given point. It is usual to say, then, that the rule and compasses are the instruments of Euclid's geometry, which is not altogether correct, unless it be remembered that with neither ruler nor compasses is a straight line allowed to be transferred, of a given length, from one part of space to another. It is a plain ruler, whose ends are not allowed to be touched, and compasses which close the moment they are taken off the paper, of which the Greek geometry permits the use. It is altogether uncertain by whom these restrictive postulates were introduced, but it must have been before the time of Plato, who was contemporary with (if he did not come after) the introduction of those problems whose difficulty depends upon the restrictions. We may here observe that in actual construction the ruler might have been dispensed with. It was reserved for an Italian abbé, at the end of the eighteenth century, when all who studied geometry had, for two thousand years, admired the smallness of the bases on which its conclusions are built, to inquire whether, small as they were, less would not have been sufficient. In Mascheroni's 'Geometria del Compassa,' published at Pavia in 1797, it is shown that all the fundamental constructions of geometry can be made without the necessity of determining any point by the intersections of straight lines; that is, by using only those of circles. This singular and very original work was translated into French, and published at Paris in 1798 and 1828.

On subjects particularly connected with the first book, see Axiom, Postulate, Parallels, Hypothenuse.

Book ii. treats of the squares and rectangles described upon the parts into which a line is divided. It opens the way for the application of geometry to arithmetic, and ends by showing how to make a rectangle equal to any rectilinear figure. It also points out what modification the proposition of Pythagoras undergoes in the case of a triangle not right-angled. [Rectangle.]

Book iii. treats of the circle, establishing such properties as can be deduced by means of the preceding books.

Book iv. treats of such regular figures as can readily be described by means of the circle only, including the pentagon, hexagon, and quindecagon. It is of no use in what immediately follows.

Book v. treats of proportion generally, that is, with regard to magnitude in general. Whether this most admirable theory, which though abstruse is indispensable, was the work of Euclid himself, or a predecessor, cannot now be known. The introduction of any numerical definition of proportion is rendered inaccurate by the necessity of reasoning on quantities between which no exact numerical ratio exists; for which see INCOMMENSURABLES. The method of Euclid avoids the error altogether, by laying down a definition which applies equally to commensurables and incommensurables, so that it is not even necessary to mention this distinction. In the article PROPORTION we shall endeavour to show that this method is more simple than is generally supposed, and also that all substitutes for it have failed in rigorous deduction.

Book vi. applies the theory of proportion to geometry, and treats of similar figures, that is, of figures which differ only in size, and not in form.

Book vii. lays down arithmetical definitions; shows how to find the greatest common measure and least common multiple of any two numbers; proves that numbers which are the least in any ratio are prime to one another, &c.

Book viii. treats of continued and mean proportionals, showing when it is possible to insert two integer mean proportionals between two integers.

Book ix. treats of square and cube numbers, as also of *plane* and *solid* numbers (meaning numbers of two and three factors). It also continues the consideration of continued proportionals, and of prime numbers, shows that there is an infinite number of prime numbers, and demonstrates the method of finding what are called *perfect* numbers.

Book x. contains 117 propositions, and is entirely filled with the investigation and classification of incommensurable quantities. It shows how far geometry can proceed in this branch of the subject without algebra; and though of all the other books it may be said that they remain at this time as much adapted for instruction as when they were written, yet of this particular book it must be asserted that it should never be read except by a student versed in algebra, and then not as a part of mathematics, but of the history of mathematics. In the article IRRATIONAL QUANTITIES we shall translate the phrases of Euclid into algebraical language, by means of which we have no doubt that many students will be enabled to read the book of Euclid with profit. The book finishes with a demonstration that the side and diagonal of a square are incommensurable. From this book it is most evident that the arithmetical character of geometrical magnitude had been very extensively considered; and it seems to us sufficiently clear that an arithmetic of a character approximating closely to algebra must have been the guide, as well as that some definite object was sought—perhaps the attainment of the quadrature of the circle.

Book xi. lays down the definitions of solid geometry, or of geometry which considers lines in different planes and solid figures. It then proceeds to treat of the intersections of planes, and of the properties of parallelopipeds, or what might be called solid rectangles.

Book xii. treats of prisms, cylinders, pyramids, and cones, establishing the properties which are analogous to those of triangles, &c., in the first and sixth books. It also shows that circles are to one another as the squares on their diameters, and spheres as the cubes on their diameters, in which, for the first time in Euclid, the celebrated METHOD OF EXHAUSTIONS is employed, which, with the theory of proportion, forms the most remarkable part of this most remarkable work. In the article just cited we have referred to the present one for some account of this method, which we now give.

The only method of reasoning upon the length, area, or solidity of curve lines or surfaces, is by observing the properties of inscribed polygons, which may, by sufficiently increasing the number of their sides or faces, be made to approach as near as we please to continued curvilinearity. But since the rigour of geometry is not content with proving that a proposition may be considered as nearly true as we please, and will not infer that one line is equal to another because it can be shown that their difference is (no matter how) small; Euclid (or some of his predecessors, but most probably Euclid, if we may judge by the character of his discoveries given by Proclus) invented this method of exhaustions, which may be considered as contained in two propositions.

I. If from A more than its half be taken, and from the remainder more than its half, and so on, the remainder will at last become less than B, where B is any magnitude named at the outset (and of the same kind as A), however small. This proposition may be easily proved, and is equally true if the proportion abstracted each time be half or less than half.

II. Let there be two magnitudes, P and Q, both of the same kind: and let a succession of other magnitudes, called X_1, X_2, X_3... be each nearer and nearer to P, so that any one, X_n, shall differ from P less than half as much as its predecessor differed. Let Y_1, Y_2, Y_3... be a succession of quantities similarly related to Q; and let the ratios of X to Y_1, of X_2 to Y_2, and so on, be all the same with each other, and the same with that of A to B. Then it must be that P is to Q as A to B. (It is obvious, from the conditions, that if X_1 be greater than P, Y_1 is greater than Q, &c., &c.) Suppose X_1, X_2, &c., less than P, and therefore Y_1, Y_2, &c., less than Q. Then if A is not to B as P to Q, A is to B as P to some other quantity S greater or less than Q: say less than Q. Then (by hyp. and I.) we can find some one of the series Y_1, Y_2... (say Y_n) which is nearer to Q than S is to Q; and which is therefore greater than S. Then since X_n is to Y_n as A to B, or as P to S, we have X_n is to Y_n as P to S, or X_n to P as Y_n to S: from which, since X_n is less than P, Y_n is less than S. But Y_n is also greater than S, which is absurd; therefore A is not to B as P to less than Q. Neither is A to B as P to more than Q (which call S) for in that case S is to P as B to A: let S be to P as Q to T, then S is to Q as P to T; from which, S being greater than Q, P is greater than T. But B is to A as S to P, that is, as Q to less than P, which is proved to be impossible by the reasoning of the last case. Consequently, A is not to B as P to more than Q, or to less than Q; that is, A is to B as P to Q. Which was to be shown. Let P and Q be two circles, A and B the squares on their diameters, X_1 and Y_1 inscribed squares, X_2 and Y_2 inscribed regular octagons, X_3 and Y_3 inscribed regular figures of sixteen sides, &c.: the preceding process gives the proof that circles are to one another as the squares on their diameters.

Book xiii., the last of those written by Euclid, applies some results of the tenth book to the sides of regular figures, and shows how to describe the five regular bodies. [SOLIDS, REGULAR.]

Books xiv. and xv., attributed to Hypsicles of Alexandria, treat entirely of the relative proportions of the five regular solids, and of their inscription in one another.

The writings of Euclid continued to be the geometrical standard as long as the Greek language was cultivated. The Romans never made any progress in mathematical learning. Boethius [BOETHIUS] translated, it is said, the first book of Euclid (Cassiodorus, cited by Heilbronner), but all which has come down to us on the subject from this writer (who lived at the beginning of the sixth century) is contained in two books, the first of which has the enunciations and figures of the principal propositions of the first four books of the Elements, and the second of which is arithmetical. Some of the manuscripts of this writer contain an appendix which professes to give an account of a letter of Julius Cæsar, in which he expresses his intention of cultivating geometry throughout the Roman dominions. But no such result ever arrived as long as the Western Empire lasted; and this short account of Roman geometry is a larger proportion of the present article than the importance of the subject warrants. These books of Boethius continued to be the standard text books until Euclid was brought in again from the Arabs.

Among the last-mentioned race geometry made no actual progress, though many of the works of the Greek writers were translated, and Euclid among the rest. There are several Arabic versions, the most perfect of which is that of Othman of Damascus, who augmented the usual imperfect translations by means of a Greek manuscript which he saw at Rome. D'Herbelot (at the words Aklides and Oclides) states that the Orientals believe Euclid to have been a native of Tyre, and also that they frequently gave his name to the science which he taught. The same author gives the names of the Arabic versions, one of which, that of Nasir eddin, the most celebrated of all, was printed

at the Medicean press at Rome in 1594. The astronomer Thabet ben Korrah [ASTRONOMY] was one of the translators, or rather, perhaps, revised the translation of Honeir ben Ishak, who died A.D. 873. There is a manuscript in the Bodleian Library, purporting to be the translation of the latter edited by the former.

The first translation of Euclid into Latin, of which the date can be tolerably well fixed, is that of Athelard, or Adelard, a monk of Bath, who lived under Henry I. (about A.D. 1150). We have given [CAMPANUS] a summary of authorities to show that Campanus, supposed to be another translator of Euclid, lived after this period; but we are inclined to believe that this translation (so called) of Campanus (printed A.D. 1482), is in fact that of Athelard, with a commentary by Campanus. For Campanus is not expressly described in the book as a translator (see article cited), but as a commentator; add to which, that there is in the Bodleian Library a manuscript entitled 'Euclidis, &c., ex versione Adelardi de Arabico, una cum commento Magistri Campani Novariensis.' Scheibel (cited by Camerer and Hauber, in the preface of their edition, presently noticed) states that in his copy of Campanus the fact of the translation being that of Adelard was noted in a handwriting apparently as old as the edition itself. The point might be settled by a comparison of the printed Campanus and the manuscript in the Bodleian. With regard to this version, it is stated (in the preface just cited) that it differs from the one of Nasireddin. With the precedent just cited, we may be allowed to state that in a copy of Campanus which we have examined, some antient handwriting, completely obliterated, is attached to Ratdolt's preface. Chemical means have succeeded in recovering a few unconnected words only, among which are 'ben Honein' and 'Tebit ben Corra,' expressing perhaps the opinion of the writer that the version chosen by Adelard or Campanus was that of the two Eastern editors who have been previously mentioned.

There is a considerable number of Greek manuscripts of the Elements, for which see Fabricius and Heilbronner. There is no account of the manuscripts which they consulted by the earlier Latin translators (from the Greek), nor by Gregory. It appears however that several, if not many, of the manuscripts are entitled Εὐκλείδου στοιχείων βιβλία ιε ἐκ τῶν Θέωνος συνουσιῶν, from which it was inferred that the compilation of the elements was the work of Theon, from the materials left by Euclid. It is certain that Theon, in his commentary on the Almagest, speaks of his edition (ἔκδοσις) of Euclid, and mentions that the part of the last proposition which relates to the sectors was added by himself. On looking at that proposition, it is found that the demonstration relative to the sectors comes after the 'ὅπερ ἔδει δεῖξαι,' with which Euclid usually ends his propositions. And Alexander, the commentator on Aristotle, who lived before Theon, calls that the *fourth* proposition of the tenth book which is the *fifth* in all the manuscripts. We can then distinctly trace the hand of Theon as a commentator, and may suspect that he performed the duty of a revising editor to the work of Euclid as it now appears; but there is not the smallest reason to suppose that Theon actually digested the work into the form which it now has. These remarks relative to the claims of Theon were first made by Sir Henry Savile, who opened the chair of geometry which he founded at Oxford by thirteen lectures on the fundamental parts of the first book of Euclid, which were delivered in 1620, and published in 1621.

We now give a short summary of the early editions of Euclid, which have appeared in Greek or Latin. It is unnecessary to specify the common editions of Simson, Playfair, &c., &c., which confine themselves to the first six books, and the eleventh and twelfth, and are generally known.

I. Editions of the whole of Euclid's works. (1.) An imperfect Latin edition, by Bartholomew Zamberti, Venice, 1505. (2.) A Latin edition, printed at Basle, marked 'Basileae apud Johannem Hervagium,' 1537, 1546, and 1558. (3.) Greek edition, with Scholia, Basle, 1539. But the principal edition of all the works of Euclid is that published by the Oxford press in 1703, under the care of David Gregory, then Savilian professor.

II. Greek editions of the Elements only. (1.) An edition curâ Simonis Grynæi, Basle, 1530. (2.) Another, with the commentary of Proclus, 'Basileæ apud Johannem Hervagium,' 1533. (3.) Greek and Italian, by Angeli Cajani, Rome, 1545. (4.) At Strasburg, 1559. (5.) Greek and Latin, with Scholia, by Conrad Dasypodius, Strasburg, 1564.

III. Latin editions of the 'Elements' only. (1) That of Campanus, the first Euclid printed, Ratdolt, Venice, 1482. (2.) A reprint of the preceding, marked 'Vincentiæ, anno salutis 1491.' (3.) An edition containing the text and comment of Campanus, from the Arabic; also the text and comment of Zamberti, from the Greek; Paris, Henry Stephens, 1505; and again in 1516. This edition is very commodious for a general comparison of the Greek and Arabic. (4.) Edition of Lucas de Burgo, Venice, 1509, according to Murhard, and 1489 according to Heilbronner, who appears to be the authority for the existence of this edition, and is doubted (with reason, we think) by Harles, in his Fabricius. (5.) Edition of Stephen Gracilis, Paris, 1557, 1573, 1578. The first edition of Clavius is that of Rome, 1574; of Commandine, Pesaro, 1572. [CLAVIUS; COMMANDINE.]

IV. Earliest editions of the Elements in modern tongues. *English*:—The Elements of Geometry of the most antient philosopher Euclid of Megara, &c., by H. Billingsley, with a preface by John Dee, London, 1570, and again in 1661. *French*:—Les quinze livres des Eléments, &c., &c., Par D. Henrion, Mathematicum, First edition, Paris, 1565? second, 1623, with various others. According to Fabricius, there was an edition by Peter Forcadel, in 1565. *German*:—Die sechs ersten bucher, &c., by William Holtzmann, Augsburg, 1562. Scheubelius had previously given the 7th, 8th, and 9th books, in 1555. *Italian*:—Euclide Megarense Philosophe, &c., per Nicolo Tartalea, Venice, 1543. *Dutch*:—De ses erste boecken Euclidis, &c., dor Jan Pieterszoon Dou, Amsterdam 1608 (or 1606). *Swedish*:—De sex forsta, &c., by Marten Stromer, Upsal, 1753. *Spanish*:—By Joseph Saragoza, Valentia, 1673. Murhard (compared with Fabricius) is the authority for all of these, except the first.

It has long ceased to be usual to read more of Euclid than the first six books and the eleventh. Those who wish to see more of the Elements will probably most easily obtain those of Williamson (London, 1788, two volumes 4to.), the translation of which is very literal. Those who prefer the Latin may find all the twelve books in the edition of Horsley (from Commandine and Gregory), Oxford, 1802. As to the Greek, the edition of Gregory is scarce, as is the edition of Peyrard, in Greek, Latin, and French, Paris, 1814; that of Camerer and Hauber, Berlin, 1824, contains the first six books in Greek and Latin, with valuable notes. The number of editors of Euclid is extremely great, but our limits will not allow of further recapitulation.

Under the names of Archimedes, Apollonius, Pappus, Proclus, Theon, &c., the reader will find further details upon the progress of Greek geometry, which continued to flourish at Alexandria till the taking of that town by the Saracens, A.D. 640. But its latter day produced only commentators upon the writers of the former, or, at most, original writers of no great note. In the following articles, LOCUS, PORISM, DUPLICATION, PROPORTIONAL, will be found some of the details of the Greek geometrical analysis. Their spherical trigonometry, or rather that portion of their geometry which supplied its place in astronomy, must be looked for under HIPPARCHUS, MENELAUS, THEODOSIUS, PTOLEMY. For some account of their arithmetical geometry, see NUMBERS, THEORY OF; IRRATIONAL QUANTITIES. The following list contains the names of the most celebrated geometers who lived before the decline of the Greek language: the dates represent nearly the middle of their lives, but are in many instances uncertain:—

Thales, B.C. 600; Ameristus? Pythagoras, 550; Anaxagoras; Œnopides; Hippocrates, 450; Theodorus; Archytas? preceptor of Plato; Leodamas; Theætetus; Aristæus, 350; Perseus? Plato, 310; Menæchmus, Dinostratus, Eudoxus, contemporaries of Plato; Neoclides; Leon; Amyclas; Theudius; Cyzicinus; Hermotimus; Philippus; Euclid, 285; Archimedes, 240; Apollonius, 240; Eratosthenes, 240; Nicomedes, 150; Hipparchus, 150; Hypsicles, 130? Geminus, 100; Theodosius, 100; Menelaus, A.D. 80; Ptolemy, 125; Pappus, 390; Serenus, 390; Diocles? Proclus, 440; Marinus? Isidorus? Eutocius, 540.

The age of Diophantus is not sufficiently well known even for so rough a summary as the preceding.

The following is the summary of books of geometrical analysis (qui ad resolutum locum pertinent), given by Pappus as extant in his time: of Euclid, the *Data*, three books of porisms, and two books *locorum ad superficiem*; of

Apollonius, two books *de proportionis sectione*, two *de spatii sectione*, two *de tactionibus*, two *de inclinationibus*, two *planorum locorum*, and eight on conic sections; of Aristæus, five books *locorum solidorum;* of Erastosthenes, two books on finding mean proportionals. But besides these he describes a book (of Apollonius) which treats *de determinatâ sectione*.

The manifold beauties of the Elements of Euclid secured their universal reception, and it was not long before geometers began to extend their results. It became frequent to attempt the restitution of a lost book by the description given of it by Pappus or others; and from Vieta to Robert Simson, a long list of names might be collected of those who have endeavoured to repair the losses of time. On the advance of geometry in general the reader may consult the lives of Vieta, Metius, Magini, Pitiscus, Snell, Napier, Guldinus, Cavalieri, Robeval, Fermat, Pascal, Descartes, Kepler, &c., &c., and also the article QUADRATURE OF THE CIRCLE.

The application of algebra to geometry, of which some instances had been given by Bombelli, and many more by Vieta, grew into a science in the hands of Descartes (1596-1650). It drew the attention of mathematicians completely away from the methods of the antient geometry, and considering the latter as a method of discovery, the change was very much for the better. But the close and grasping character of the antient reasoning did not accompany that of the new method: algebra was rather a half-understood art than a science, and all who valued strictness of demonstration adhered as close as possible to the antient geometry This was particularly the case in our own country, and unfortunately the usual attendants of rigor were mistaken for rigor itself, and *vice versâ*. The algebraical symbols and methods were by many reputed inaccurate, while the same processes, conducted on the same principles, in a geometrical form, were preferred and even advanced as more correct. Newton, an admirer of the Greek geometry, clothed his Principia in a dress which was meant to make it look (so far as mathematical methods were concerned) like the child of Archimedes, and not of Vieta or Descartes: but the end was not attained in reality, for though the reasoning is really unexceptionable, yet the method of exhaustions must be applied to most of the lemmas of the first section, before the Greek geometer would own them.

The methods of algebra, so far as expressions of the first and second degrees are concerned, apply with great facility to many large classes of questions connected with straight lines, circles, and other sections of the cone. Practical facility was gained by them, frequently at the expense of reasoning: the time came when a new Descartes showed how to return to geometrical construction with means superior to those of algebra, in many matters connected with practice. This was Monge, the inventor of *descriptive geometry*. The science of perspective and many other applications of geometry to the arts had previously required isolated methods of obtaining lines, angles, or areas, described under laws not readily admitting of the application of algebra, and its consequence, the construction of tables. The descriptive geometry is a systematized form of the method by which a ground-plan and an elevation are made to give the form and dimensions of a building. The projections of a point upon two planes at right angles to one another being given, the position of the point itself is given. From this it is possible, knowing the projections of any solid figure upon two such planes, to lay down on either of those planes a figure similar and equal to any plane section of the solid. In the case where the section is a curve it is constructed by laying down a large number of consecutive contiguous points. The methods by which such an object is to be attained were generalized and simplified by MONGE, whose *Géométrie Descriptive* (the second edition of which was published in 1820) is one of the most elegant and lucid elementary works in existence.

The methods of descriptive geometry recalled the attention of geometers to the properties of projections in general, of which such only had been particularly noticed as could be applied in the arts of design or in the investigation of primary properties of the conic sections. From the time of Monge to the present this subject has been cultivated with a vigour which has produced most remarkable results, and promises more. Pure geometry has made no advance since the time of the Greeks which gives greater help to its means of invention than that which the labours of what we must call the school of Monge have effected. On this point we shall refer to PROJECTIONS, THEORY OF. One of the most distinguished pupils of this great master, M. Chasles, has just published an 'Aperçu historique des méthodes en Géométrie,' forming the eleventh volume of the 'Mémoires Couronnés' of the Academy of Brussels. The very recent date of this work has prevented us from being able to say more than that it appears to be sufficiently learned in matters of antient geometry, and that it offers a most satisfactory view of the progress of all ages, in connexion with those generalized methods of which its object is to treat.

On the history of geometry, as distinguished from other parts of mathematics, there is very little to cite. The references in the article MATHEMATICS may be consulted.

GEOMETRY OF THE GREEKS. [GEOMETRY.]

GE'OMYS. [MURIDÆ.]

GEOPHO'NUS. [FORAMINIFERA, vol. x., p. 348.]

GEOPO'NIKA (or, a 'Treatise on Agriculture,') is the title of a compilation, in Greek, of precepts on rural economy, extracted from antient writers. The compiler, in his proemium, shows that he was living at Constantinople, and dedicated his work to the emperor Constantine, 'a successor of Constantine, the first Christian emperor,' stating that he wrote it in compliance with his desire, and praising him for his zeal for science and philosophy, and for his philanthropy. This emperor is supposed by some to have been Constantine Porphyrogenitus, and the compilation is generally ascribed to Cassianus Bassus, a native of Bithynia, who however is stated by others to have lived some centuries before the time of Porphyrogenitus. The question of the authorship of the 'Geoponika' has excited much discussion. Needham, in his Greek and Latin edition of the 'Geoponika,' Cambridge, 1704, has treated the subject at great length. The work is divided into twenty books, which are subdivided into short chapters, explaining the various processes of cultivation adapted to various soils and crops, and the rural labours suited to the different seasons of the year; with directions for the sowing of the various kinds of corn and pulse; for the training of the vine, and the art of wine-making, upon which the author is very diffuse. He also treats of olive plantations and oil-making, of orchards and fruit-trees, of evergreens, of kitchen-gardens, of the insects and reptiles that are injurious to plants, of the economy of the poultry-yard, of the horse, the ass, and the camel; of horned cattle, sheep, goats, pigs, &c., and the care they require; of the method of salting meat; and, lastly, of the various kinds of fishes. Every chapter is inscribed with the name of the author from whom it is taken, and the compiler gives at the beginning of the first book a list of his principal authorities, who are Africanus, Anatolius, Apuleius, Berytius, Damogeron, Democritus, Didymus, Dionysius Uticensis the translator of Mago the Carthaginian writer on agriculture, Diophanes, Florentinus, Leontius, Pamphilus, Paxamus, the Quintilii, Sotion, Varro, Vindanonius, and Zoroaster. Other authors besides these are quoted in the course of the work. Two or three chapters are inscribed with the name of Cassianus, who speaks of himself in them as a native of Maratonymus in Bithynia, where he had an estate. (*Geoponika*, book v., ch. 6 and 36.) The work is curious, as giving a course of antient agriculture collected from the best authorities then existing. The best edition of the 'Geoponika' is that of N. Niclas, in Greek and Latin, with notes and indexes, 4 vols. 8vo., Leipzig, 1781.

GEORGE (LOUIS) I., king of Great Britain. After the exclusion of James II. and his son in 1689, the nearest heirs to the throne in the lineal order of succession were—1. The Princess Mary of Orange, eldest daughter of James II.; 2. The Princess Anne of Denmark, younger daughter of James II.; 3. William prince of Orange, son of Mary, eldest daughter of Charles I. By the declaration of both houses of the convention on the 12th of February, 1689, it was resolved that after the decease of the prince and princess of Orange, the crown should descend, first, 'to the heirs of the body of the said princess; and for default of such issue, to the Princess Anne of Denmark, and the heirs of her body; and for default of such issue, to the heirs of the body of the said prince of Orange.' This settlement was confirmed in the second session of the first parliament of William and Mary, by the statute, 1 W. and M., s. 2, c. 2, commonly called the Bill of Rights. (Vol. iv. p. 404.) In the preceding session however, when

the Bill of Rights was first brought forward, the king had instructed his ministers to propose a clause for a further limitation of the succession, failing heirs of his own body, to the Electress Sophia of Hanover. The electress of Hanover (or, as appears to be the more correct electoral style, of Brunswick and Lüneburg), being the youngest of the ten children of Elizabeth, queen of Bohemia, the daughter of James I., stood in the regular order of inheritance, not only after the descendants of Henrietta, the younger daughter of Charles I., from whom sprung the royal houses of Savoy, France, and Spain, but also after the descendants of her own elder brothers, Charles Louis, Elector Palatine, the ancestor of the houses of Orleans and Lorraine, and Edward, through whom the houses of Salm, Ursel, Bourbon, Conty, Maine, Modena, and the Imperial family were brought into the line of succession. All these families however were Catholic; that of Hanover was the nearest Protestant family after the house of Orange. The proposition for the insertion of the name of the Princess Sophia in the bill respecting the settlement of the succession was made, according to the king's desire, in the House of Lords, and adopted there; but when the bill was sent down to the Commons, the clause was opposed both by the Tory and by the Republican parties, though on opposite principles, and was thrown out in spite of all the exertions of the Court. The consequence was, that after the bill had been under discussion for about two months, it was for the present allowed to drop altogether, on the birth (24th July) to the Princess Anne of a son, William, afterwards proposed to be created duke of Gloucester (he died before the patent passed the great seal), by which it seemed to be rendered of less pressing importance. When it was brought in again in the following session, the proposition respecting the Princess Sophia was not renewed; but by a clause excluding Papists, the succession, as King William himself expressed it in writing to her on the subject, was 'in a manner brought to her door.' The death of Queen Mary however (January 1, 1695), and that of the duke of Gloucester, the last of seventeen children that had been born to the princess of Denmark (30th July, 1700), made it extremely desirable that the matter of the succession should no longer remain unsettled. The subject accordingly was strongly recommended to the attention of parliament in the royal speech delivered February 10, 1701. The recommendation was coldly received by the majority of the House of Commons; but at length, by the contrivance, it is said, of the parties opposed to the scheme, the further limitation of the crown to the Electress Sophia and her heirs was formally proposed by Sir John Bowles, 'who,' says Tindal, 'was then disordered in his senses, and soon after quite lost them.' It is affirmed that a proposition was now made by several influential members of the Upper House to the ambassador of the duke of Savoy, that that prince should send one of his sons to be educated as a Protestant in England, in which case they gave their assurance that the plan of the Hanoverian succession should be defeated; but the duke would not consent. Meanwhile a bill, founded on the motion of Sir John Bowles, was introduced into the House of Commons; and although it remained in suspense for many weeks, it was eventually carried through both houses. This is the 12th and 13th Will. III., c. 2, which declares that the crown of England, France, and Ireland, 'after his majesty and the Princess Anne of Denmark, and in default of issue of the said Princess Anne and of his majesty respectively,' should descend 'to the most excellent Princess Sophia, electress and dutchess dowager of Hanover, and the heirs of her body, being Protestants.' The settlement thus made was further confirmed the next session by the 13th Will. III., c. 6, called the Abjuration Act, from the oath abjuring allegiance to the pretender therein enjoined to be taken and subscribed. The clause imposing this oath was carried in the House of Commons by only one vote; the Tories, by whom it was opposed, endeavouring to strengthen their cause by insinuations (which were most probably entirely without foundation) that the Court now meditated the bringing in of the Hanover family even before the Princess Anne. Several attempts were made after this to prevail upon the parliament of Scotland to adopt the same settlement for the crown of that kingdom which had thus been established for the English crown; but they were all ineffectual, till the object was at last accomplished in 1706 by the Treaty of Union, the second article of which declared 'that the succession to the monarchy of the United Kingdom of Great Britain, and of the dominions thereunto belonging, after her most sacred majesty, and in default of issue of her majesty, be, remain, and continue to the most excellent Princess Sophia, electress and duchess dowager of Hanover, and the heirs of her body, being Protestants, upon whom the crown of England is settled' by the act already mentioned. Before this, by the 4 Anne, c. 1 and 4, the Princess Sophia, 'and the issue of her body, and all persons lineally descending from her, born or hereafter to be born,' were naturalized, so long as they should not become Papists. By the 4 Anne, c. 8, also, the next Protestant successor to the throne was empowered to name any additional number of persons to act with seven lords-justices appointed in the statute to administer the government between the death of the queen and the arrival of the said successor in the kingdom. Most of these arrangements were confirmed by various clauses in the 6th Anne, c. 7, entitled 'An Act for the Security of Her Majesty's Person and Government, and of the Succession to the Crown of Great Britain in the Protestant Line.' Finally, by the 10th Anne, c. 4, passed in 1711, precedence was given to the Princess Sophia, to 'the most serene elector of Brunswick Lunenburgh, her son and heir-apparent, the most noble George Augustus, electoral prince of Hanover and duke of Cambridge, only son of the said most serene elector, and also the heirs of the body of the said most excellent princess, being Protestants, before the archbishop of Canterbury, and all great officers, and the dukes, and all other peers of these realms.' The Hanoverian succession was guaranteed by the treaty concluded with the United Provinces of Holland in 1706, by the Barrier Treaty between Great Britain and Holland in 1709, and by the Treaty of Guarantee between the same powers in 1713; and the validity of the settlement was acknowledged by the Treaties of Peace concluded in the last-mentioned year, at Utrecht, between Great Britain and France, and between Great Britain and Spain. (*General Collection of Treaties*, vol. i. p. 434; vol. ii., p. 479; and vol. iii., pp. 361, 398, and 470.)

After the accession of Anne, no party affected so great a zeal for the Hanoverian succession as the extreme section of the Tories, or Jacobites, whose object, of course, was anything rather than really to support the parliamentary settlement. In 1705, Lord Rochester, one of the heads of this faction, first intimated obscurely in the House of Lords, and more openly among his friends, his intention of proposing that the Electress Sophia should be invited to come over to reside in England. 'It was thought,' says Tindal, 'that they either knew or apprehended that this would not be acceptable to the queen; and they, being highly displeased with the measures she took, went into this design both to vex her and in hopes that a faction might arise out of it, which might breed a distraction in our councils, and some of them might hope thereby to revive the Pretender's claim.' The proposition was also, obviously enough, calculated to be very embarrasing to the Whigs, who if they assented to it would probably cut themselves off from all chance of the favour of the court, of which they were at this time in expectation, while by resisting it they would endanger both their popularity with the nation and also perhaps the confidence of the Hanoverian family. The next session a motion that the heiress presumptive to the throne should be invited over was formally made in the House of Lords by Lord Haversham, but after a warm debate (at which the queen was present), it was rejected by a great majority. Some years after, in altered circumstances, nearly the same game was attempted to be played by the Whigs, at whose instigation, in April, 1[illegible] the Hanoverian resident, Baron Schütz, suddenly made application to the Lord Chancellor Harcourt for a writ of summons to the House of Lords to the Electoral Prince (afterwards George II.), who had been made a British Peer in 1706, by the title of Duke of Cambridge. This application, and a report which was at the same time spread that the Duke of Cambridge would in any circumstances immediately come to England, threw the ministry into no small perplexity, and so greatly annoyed and irritated the queen that she forbade Baron Schütz to appear at court. The following year however another report was spread, that the Princess Sophia intended to solicit permission from her majesty for the Electoral Prince to come to England. On this the queen wrote both to the Princess, to her son the Elector, and to the Electoral Prince himself, expressing her disapprobation of the project in the strongest terms. The letters to the Princess and the Elector (dated St. James's,

19th May, 1714), have been published, but that to the Electoral Prince is said to have been in a style so unbecoming both the writer and the person addressed, that it could not be given to the world. These letters may be said to have killed the heiress presumptive; she was so much affected by them, that on the day after their receipt, the 28th of May, she was struck with apoplexy as she was walking in the gardens of Herenhausen, and expired in the arms of her daughter. The Princess Sophia, who was one of the most accomplished women of her time, was in her eighty-fourth year when her life was thus terminated. Queen Anne died on the 1st of August following, on which George, Elector of Brunswick, the son of the Electress Sophia, became king of Great Britain.

George I. was born 28th May, 1660 (the day before that on which Charles II. made his entry into London at the Restoration). In 1681 he came over to England with the intention of paying his addresses to the Princess (afterwards Queen) Anne; but immediately after landing he received his father's orders not to proceed in the business, on which he returned home, and in the following year married his cousin Sophia Dorothea, the daughter of the Duke of Zell. He afterwards served in the armies of the Empire both against the Turks and the French. He succeeded to the electorate on the death of his father in 1698. In 1700 he led a force to the assistance of the Duke of Holstein, who was attacked by Frederick IV. of Denmark, and, in conjunction with the Swedes under General Banier, compelled King Frederick to raise the siege of Tonningen. Hanover had been created a ninth electorate by the Emperor Leopold in 1692, but in consequence of the opposition of other electoral houses it was not till 1708 that the duke was admitted into the college of electors. Duke Ernest, the father of George I., had originally attached himself to the French interest, but his adhesion to England was of course secured by the settlement of the succession to the crown on his family, although it is probable that neither he nor even his son regarded that arrangement as very secure until the latter actually found himself seated on the throne. The Elector George remained steady to the English alliance throughout the general war which began in 1702, and both in 1707 and the two following years he commanded the Imperial forces against the French. All the endeavours of the English ministry however could not prevail upon him to go along with them in the original propositions for the peace of Utrecht. To all the arguments and solicitations addressed to him on that occasion, he answered that he desired to be spoken to simply as a German Prince, and that no consideration of any future connexion he might have with Great Britain should for the present induce him to depart from what he held to be the true interest of the Empire. In fact, he stood out till the conclusion of the treaty of peace between the French King and the Emperor, at Rastadt, 6th March, 1714.

The accession of George I. took place as quietly, and as much like a thing of course, as any such change has ever done in the most settled times. The new king, with the prince his son, arrived at Greenwich on the 28th of September, 1714. Before this the Tories, who had been in power at the death of Queen Anne, had all been dismissed by the Lords Justices; and now a new ministry was formed consisting, with the single exception of the earl of Nottingham (who was removed within a year), wholly of Whigs, Viscount Townshend and the celebrated Mr. (afterwards Sir Robert) Walpole being its most influential members. A new parliament, which gave ministers a great majority in the Commons, having assembled in January, 1715, immediately proceeded to the impeachment of Bolingbroke, Oxford, and their associates, all of whom were compelled for the present to bend to the storm. These determined (or, as some called them, vindictive) measures however probably did not do much to strengthen the position of the new dynasty. The rebellion in Scotland broke out before the end of the year, and was not completely put down till February, 1716. [Scotland.] One of the consequences by which it was followed was the repeal of the Triennial Act by the 1st Geo. I, stat. 2, c. 38, entitled '*An Act for enlarging the time of continuance of parliaments*,' by which it was declared that not only all future parliaments, but even the parliament then sitting, might be continued for seven years,—certainly the most daring assumption of power upon which an English parliament has ever ventured. The year 1717 was ushered in with the rumour of an intended invasion of the country by Charles XII. of Sweden, who had been irritated by the recent purchase by the king of England, from the Danes, of the two duchies of Bremen and Verden, which the latter had taken from Sweden in 1712. To counteract the designs of Sweden, to which the Czar Peter of Russia had been induced to become a party, George I. lost no time in arranging what was called the Treaty of Triple Alliance (concluded at the Hague 4th of January, 1717) with France and Holland. This war however was not marked by any operations of importance, and it was put an end to by the death of Charles XII. before the end of the following year. Meanwhile, in April, 1717, the ministry of Townshend and Walpole was broken up by the dismissal of the former and the immediate resignation of the latter—the result of internal dissensions which had been for some time growing, and of the intrigues of a section of the Whig party. The heads of the new cabinet were Mr. (afterwards Lord) Stanhope, who became first lord of the treasury and chancellor of the exchequer in the room of Walpole, and the earl of Sunderland, who took the office of one of the principal secretaries of state, Mr. Addison being taken in as the other. The intrigues of Cardinal Alberoni, which had also been at the bottom of the late demonstrations of hostility by Sweden, now led to a war with Spain. Here England was again cordially assisted by France, the Spanish minister's ambitious designs embracing at once the expulsion of the Hanoverian family from the government of the former, and of the Regent Duke of Orleans from that of the latter. The Quadruple Alliance between Great Britain, France, the Emperor, and Holland was now arranged, and various military operations took place, the most distinguished of which was the victory obtained by Admiral Sir George Byng (afterwards Lord Torrington) over the Spanish fleet off the coast of Sicily (31 July, 1718), in which about fifteen of the enemy's ships were captured or destroyed. In June, 1719, also, a Spanish force that had landed in Scotland, and had been joined by a body of Highlanders under the command of the Earl Marischal and Lord Seaforth, was defeated by General Wightman in an action fought at Glenshield, in Inverness-shire, and compelled to surrender at discretion—a check by which a second Jacobite rebellion was at once put down. The differences with Sweden however were finally accommodated by the treaty of Stockholm, signed the 20 November, 1719; and before the close of the same year Cardinal Alberoni was dismissed by the king of Spain, and peace was soon after made also with that power. A concurrence of events now brought about a change of ministry. In April, 1720, a reconcilement was effected between the king and the prince of Wales, with whom he had been for some years at variance; this re-introduced Walpole, who had attached himself to the prince, into the ministry in the subordinate capacity of paymaster of the forces, and soon after the terrible explosion of the South Sea scheme at once overthrew the administration of Stanhope and Sunderland by the extent to which several members of the cabinet were personally involved, and produced a crisis in which Walpole, with his great financial skill and reputation, found every thing thrown into his own hands. He became again first lord of the treasury and chancellor of the exchequer in April, 1721, commencing from that date a premiership which lasted for twenty-one years, being the longest period that any English minister has continued in power since the time of Lord Burleigh. Of the transactions in domestic politics under the late administration, the most remarkable were the repeal in 1718 of the Schism Act, passed in the last year of Queen Anne—a repeal which, to his discredit, Walpole, actuated by considerations of party, opposed to the utmost, though happily without success; and the attempt of the ministers in 1718 and 1719 to carry their celebrated bill for the limitation of the peerage, in which they were defeated by the junction of Walpole with the Tories.

The pacific dispositions of Walpole, and the continued friendship of France, both under the government of the duke of Orleans and afterwards under that of Cardinal Fleury, tended to preserve the repose of Europe during the latter years of the reign of George I.; but it was, on the other hand, constantly endangered both by the persevering intrigues of the adherents of the family that had been ejected from the British throne, and still more by the apprehensions of the king for the safety of his German dominions, and the entanglement of the country in continental politics through that connexion. The most memorable event of 1722 was the detection of the conspiracy for bring-

ing in the Pretender, in which the celebrated Atterbury, bishop of Rochester, was involved. War was at length rekindled by the alliance formed between the king of Spain and the emperor by the treaty of Vienna, signed the 30th of April, 1725, and the treaty of Hanover, concluded the third of September following, between England, France, and Prussia, to which Sweden afterwards acceded. The siege of Gibraltar was begun by Spain in February, 1726, and a British fleet was about the same time sent to the West Indies under command of Admiral Hosier, where in consequence of contradictory or indecisive orders it remained inactive till the admiral and nearly all his crew perished of disease—a calamity which at the time occasioned a vehement outcry against the administration. Preliminary articles for a general pacification however were signed at Paris, 31st May, 1727. On the 3rd June following, king George embarked at Greenwich for Hanover, but had only reached Osnaburg when he was struck with apoplexy, and died there in the night between the 10th and 11th June, in the sixty-eighth year of his age, and the thirteenth of his reign.

By his unfortunate queen, who died 2nd November, 1726, at the castle of Ahlen in Hanover, in which she had been immured since 1694, on a charge, never proved and generally disbelieved, of an intrigue with Count Koningsmark, George I. had one son, George, by whom he was succeeded, and a daughter, Sophia Dorothea, born 16th March, 1687, and married in 1706 to king Frederick II. of Prussia. George I. has the credit of not having allowed himself to be influenced in affairs of state by the female favourites with whose society he solaced himself. Of these one who enjoyed his chief favour after he came to the English throne was Erengard Melosine de Schulenberg, who in 1716 was created duchess of Munster, in the Irish peerage, and in 1719 duchess of Kendal, in the English peerage, for life, her niece Melesine de Schulenberg (afterwards married to Philip earl of Chesterfield) being also made countess of Walsingham for life in 1722. This woman, who survived till 1743, the king is believed to have married with the left hand. His other chief mistress in his latter days was Charlotte Sophia, wife of Baron Kilmansegg, countess of Platen in Germany, and created countess of Leinster in Ireland, 1721, and countess of Darlington in England, 1722, who died in 1730.

A fair share of the courage and obstinacy of his race, steadiness to his engagements and his friendships, and considerable sagacity in the management of affairs, were the marked qualities in the character of this king. He was to the end of his life however in all his views and notions, and in his conduct, much more elector of Hanover than king of England; and his excessive anxiety about not merely the safety but the extension of his hereditary dominions undoubtedly helped to involve this country in the net of continental politics to an extent not before known. Other circumstances of the time however also contributed to this result. George I. is said to have had little taste for literature, science, or the fine arts; but the country is indebted to him for the foundation (in 1724) of a professorship of modern history in each of the universities.

It is impossible within the limits to which we are confined to attempt even the most general account of the changes made in the law by the many hundred pages of legislation which were added to the Statute Book in the course of this reign. Among the most remarkable of the new laws may be mentioned the 1 Geo. I. st. 2, c. 5, commonly called the Riot Act; the 6 Geo. I. c. 5, which declared that the 'kingdom of Ireland hath been, is, and of right ought to be subordinate unto and dependent upon the Imperial crown of Great Britain; and that the British parliament had, hath, and of right ought to have, power and authority to make laws and statutes of sufficient force and validity to bind the kingdom and people of Ireland,' but which was repealed by † the 22 Geo. III. c. 53; the 9 Geo. I. c. 22, commonly called the Black Act (from the name of the 'Blacks' taken by one of the descriptions of depredators against which it is directed); and the 11 Geo. I. c. 26, entitled 'An Act for the more effectual disarming the Highlands in Scotland, and for the better securing the peace and quiet of that part of the kingdom.' The commencement of this reign also forms an important æra in the history of the national finances, from the establishment in 1716, under the government of Walpole, of the first sinking fund on a great scale, by the 3 Geo. I. c. 7. The national debt, which amounted to about 52,000,000*l.* at the commencement of this reign, underwent no reduction in the course of it; but the interest was reduced from about 3,350,000*l.* to 2,217,000*l.* The power of effecting this reduction was principally obtained through the effects of an act passed in the last year of the preceding reign (the 12 Anne, st. 2, c. 16), by which the legal interest of money was reduced from 6 to 5 per cent.

GEORGE (AUGUSTUS) II., king of Great Britain, the only son of George I. and his queen Sophia Dorothea, was born at Hanover, October 30, 1683. On the 22nd August, 1705, he married Wilhelmina Caroline, daughter of John Frederick, margrave of Brandenburg Anspach. On the 9th November, 1706, he was created a British peer by the title of duke of Cambridge; but he never received a writ of summons to the House of Lords, nor indeed did he visit England till his father succeeded to the throne. The project that was at one time entertained of bringing him over has been noticed in the preceding article. In the war with France he served with his father in the army of the allies, and particularly distinguished himself at the battle of Oudenarde, gained 11th July, 1708, by the duke of Marlborough over the French forces commanded by the duke of Burgundy. On the death of Queen Anne he accompanied his father to England, and was declared prince of Wales at the first privy-council held by George I. 22nd September, 1714. The heir-apparent was immediately seized upon as an instrument of political intrigue. In the debates on the civil list in May, 1715, one of the propositions of the tories was to settle an independant revenue of 100,000*l.* per annum on the prince of Wales, but the motion to that effect was negatived in the House of Commons by a great majority. The same sum however was allowed to the prince by the king out of the income of 700,000*l.* voted to his majesty by parliament. On the 5th May, 1715, the prince received the appointment of captain-general of the Artillery Company; and on the 6th July, 1716, he was constituted guardian of the realm and lieutenant of the king during the king's absence in Hanover. While thus left to administer the government, he was present on the 6th December at Drury Lane Theatre, when a lunatic, of the name of Freeman, a man of property in Surrey, suddenly rushed towards the box where he was, fired at the sentinel who endeavoured to stop him, and severely wounded him in the shoulder, and was not secured without great difficulty, when three other loaded pistols were found about his person. In the general confusion and alarm, the prince is said to have shown perfect presence of mind and self-possession. A quarrel between the king and the prince broke out on the 28th November, 1717, on occasion of the baptism of a son of which the princess of Wales had been delivered on the 3rd of that month; the immediate cause of the rupture was the displeasure expressed by the prince at the duke of Newcastle standing godfather with the king, instead of the king's brother, the duke of York, whom he wished to have been appointed. 'But it seems,' observes a contemporary writer (Salmon, in 'Chronological Historian'), 'there were other reasons of this misunderstanding, with which we are not to be acquainted.' The next day the king sent his commands to the prince to keep his own apartment till his pleasure should be further known: soon after he was desired to quit St. James's, on which his royal highness and the princess went to the house of the earl of Grantham, in Albemarle Street. The children however, by the king's order, remained at St. James's; and shortly after, the judges, being consulted, decided, by a majority of ten to two, that the care of the education of the royal family belonged of right to the king. (See an account of the proceedings in Hargrave's *State Trials*, xi., 295-302.) At this time the family of the prince of Wales consisted of a son, Frederick Lewis, born in 1707, and three princesses, Anne, born 1709, Amelia, born 1711, and Caroline, born 1713, besides the infant Prince George William, who died in the beginning of the following year. On the 24th December his majesty's pleasure was formally signified to all the peers and peeresses, and to all privy-councillors and their wives, that all persons who should go to see the prince and princess of Wales should forbear coming into his majesty's presence; such persons also as had employments both under the king and prince were obliged to quit the service of one of them. According to Tindal, the king also consulted the judges whether he could retain for the maintenance of the children some part of the 100,000*l.* granted by parliament to the prince. It does not appear

that any such grant was ever made by parliament; but by the 1 George I. st. 2, c. 22, it was enacted that his majesty's grant of 100,000*l*. per annum to the prince of Wales should be paid without fees and free from taxes; and that it might be specially charged on such branches of customs and excise as were applicable to the civil-list, which may have been considered as a parliamentary sanction of the grant. The judges, Tindal adds, were divided upon this point, but seemed rather to favour the prince; on which 'the prince and princess stood their ground; and though they left to the king the education of their children, they refused to contribute towards the expense.' The king formed a household for the young princesses, and on the 10th January, 1718, he created his grandson, Prince Frederick Lewis, duke of Gloucester.

The king paid another visit to Hanover in May, 1719. On this occasion 'the prince and princess of Wales,' says Tindal, 'not being appointed regents, retired into the country, and appeared no more till the king's departure, a few days after which they came to St. James's to see the young princesses, who kept a levee twice a week; and to them it was that the lords-justices and a numerous appearance of foreign ministers, nobility, and gentry, made their compliments on the king's birthday.' It is believed that the famous Peerage Bill of this year [GEORGE I.] was brought forward chiefly in consequence of the quarrel between the king and his son, and with the view of limiting the powers of the latter when he should come to the throne. In the final discussion which it underwent in the House of Commons in November, Sir John Packington observed that some persons had through indiscretion occasioned an unhappy difference in the royal family, and he was apprehensive if that bill, so prejudicial to the rights of the next heir, should pass into a law, it might render that difference irreconcilable. The allusion here was understood to be to the earl of Sunderland, then first lord of the treasury and prime minister, the mover and most zealous promoter of the bill.

The reconciliation of the king and the prince was at last effected in April, 1720, chiefly by the endeavours of the duke of Devonshire and Mr. Walpole, who had for some time past attached themselves to the court of his royal highness. On the 23rd of that month an interview took place between the father and son; and the termination of their difference was immediately announced to the public by the prince, on his return to Leicester-house, being attended by a party of the yeomen of the guard and of the horse-guards, and by the foot-guards beginning to mount guard at his house. The reconciliation however was probably never very cordial. It may be observed that when the king immediately after this set out to pay another visit to his continental dominions, he left the government in the hands of lords-justices, as on the last occasion. A story is told by Horace Walpole which appears to show that the king's animosity lasted to the end of his life. After having destroyed two wills which he had made in favour of his son, he had entrusted a third, supposed to have been of an opposite character, to the keeping of Wake, archbishop of Canterbury, who on the accession of George II. presented it to the new king. To the surprise of every one present, his majesty, putting it into his pocket, stalked out of the room, and the will was never heard of more. Lord John Russell, in relating this story (*Memoirs of Affairs of Europe*, ii. 396) observes that 'by the law of England the will would not have been valid; all property, real as well as personal, of the king, descends with the crown.' It does not appear to be now understood that this is law.

George II. succeeded his father, 10 June, 1727. It was at first his intention to place at the head of the government Sir Spencer Compton (afterwards earl of Wilmington), who was then the speaker of the House of Commons; but when that person received the royal commands to draw up the declaration to the privy-council, he was obliged to call in Walpole to assist him. Queen Caroline, whose influence with her husband was very great, now interposed; and the result was that Walpole was continued in office. The war with Spain was finally terminated by the treaty of Seville, concluded 9th November, 1729; and for ten years from this time Walpole contrived to preserve peace. New causes however of dissatisfaction with Spain arose, principally out of alleged interferences of that power with the freedom of English commerce; and the minister at last found it impossible to resist the cry of the country for a new war. Hostilities were commenced in the close of the year 1739; and the reduction of Portobello, on the isthmus of Darien, by Admiral Vernon, in the beginning of the following year, still further sharpened the eagerness with which the popular feeling had rushed into the contest. The operations that were subsequently attempted however were not equally successful; repeated attacks upon Carthagena, in particular, all signally failed. The death of the emperor Charles VI. in October, 1740, speedily produced a general European war; Great Britain supporting the settlement called the Pragmatic Sanction, by which the succession to the Austrian dominions devolved upon the late emperor's eldest daughter, Maria Theresa, queen of Hungary; France and Spain uniting to maintain the claims of Charles Albert, elector of Bavaria (elected emperor in 1742 under the title of Charles VII.). Meantime various causes had been co-operating to shake Walpole's power. The mere length of his tenure of office had tired the country and created impatience for a change. The pacific policy in which he had so obstinately persevered had disgusted the general eagerness for a war excited by a feeling that the national interest and honour alike demanded recourse to arms, and the course he had taken in this respect had impaired his reputation as much as his popularity. His scheme for the extension of the excise, introduced in 1733, had, although abandoned, produced an unfavourable impression that sunk deep into the popular mind, and an outcry against him that never subsided. The loss of his steady and influential protectress, Queen Caroline, who died 20th November, 1739, deprived him of one of his strongest supports in the favour both of the king and the nation. Just before that event also a violent quarrel had broken out between the king and the prince of Wales, who now headed the opposition, and collected around him at Leicester-house a court and party, one of the chief of whose avowed objects was the removal of the premier. In these circumstances a new parliament met 4th December, 1741, in which Walpole soon found himself so placed as to make it necessary to retire. He resigned all his places in the end of January, 1742, and was immediately created earl of Orford. So long as he lived however, which was not more than three years, Walpole continued really the king's chief adviser. The ministry that immediately succeeded was nominally appointed by his great rival Pulteney, but it was in reality the result of a compromise, and Pulteney himself was by Walpole's contrivance annihilated in the very moment of his apparent triumph, by being compelled to leave the House of Commons and to take a peerage: as earl of Bath he became at once nobody. A reconciliation at the same time took place between the king and the prince; but neither this nor any of the other arrangements lasted long. In a few months the prince was again in opposition, and the new ministry was assailed by an adverse force, composed in part of their antient allies, as formidable as that which had driven Walpole from power.

Meanwhile the war against the Bavarians and their allies the French had begun to be prosecuted with great vigour; the kings of Denmark and Sweden (the latter in his capacity of landgrave of Hesse Cassel) having been subsidized, and a treaty of alliance concluded with Frederick III. of Prussia, George II. joined his army on the Continent in person in the beginning of June, 1743, and on the 26th of that month shared in the great victory gained over the French at Dettingen. On this occasion the English king behaved with distinguished courage. This instance of success however was only followed by inactivity and reverses; one consequence of which was the expulsion from the ministry, in November, 1744, of Lord Granville (formerly Lord Carteret), the great promoter of the war, and as such the member of the cabinet who had the greatest influence with the king. The ministry that was now formed was called the Broad-Bottom ministry: it contained a few tories, but consisted principally of the Newcastle and Grenville whigs, the only parties wholly excluded being the connexions of lords Granville and Bath. Mr. Pelham, brother of the duke of Newcastle, was first lord of the treasury and chancellor of the exchequer, and Mr. Pitt (afterwards so distinguished both under that name and as earl of Chatham) being promised a place as soon as the king could be induced to admit him, gave his support in the meantime to the administration. This change of men however brought no change of measures. The king's German politics continued to receive the same support from the new ministry as they

had from the old. Nor was the war carried on with better fortune. The defeat of the allies at Fontenoy, 30th April, 1745, was the great event of the next campaign.

In August of the same year another Jacobite rebellion, instigated by France and Spain, broke out in Scotland; the towns of Dunkeld, Perth, Dundee, Edinburgh, and Carlisle, rapidly fell into the hands of the insurgents; the king's troops were routed at Preston-pans and Falkirk; and the Pretender, Charles Edward, had already advanced as far as Derby in his bold march upon the metropolis of the empire before any successful attempt was made to resist him. The rising however which had worn so threatening an aspect was completely put down by the victory of Culloden gained by the king's second son, the duke of Cumberland, 16th April, 1746. In the preceding February, in the very midst of the public alarm, the king had made a sudden attempt to reinstate lords Granville and Bath as the heads of the ministry; but after being three days in office they saw that the project was hopeless; on which Mr. Pelham, who had resigned, was taken back, and continued at the head of affairs till his death in 1754.

The treaty of Aix-la-Chapelle, the preliminary articles of which were signed 30th April, 1748, at last put an end to the war, the latter years of which were distinguished by some brilliant naval successes on the part of Great Britain. The conditions of this peace on the whole excited great dissatisfaction in England, especially the restoration of Cape Breton, which had been taken from the French in 1745, and had been accounted the great acquisition of the war. On the other hand Madras, which a French fleet had reduced in 1746, was recovered. The power of the ministry however was not shaken by the vigorous and persevering assaults upon the treaty by the opposition in parliament; and Mr. Pelham and his friends also triumphed in a division that broke out in the cabinet after the death of the prince of Wales (20th March, 1751), on the subject of the Regency Bill rendered necessary by that event, when the Pelhams, to whom Mr. Pitt attached himself, were opposed by the party of the dukes of Cumberland and Bedford, and their protegé Mr. Fox, the origin of a long and still unextinguished rivalry. But the death of Mr. Pelham, 6th March, 1754, produced a succession of new contentions, intrigues, and changes. At last, in November, 1755, Pitt and his friends were dismissed, and Fox, as secretary of state and manager of the House of Commons, became, under the duke of Newcastle, who since his brother's death had held his offices and nominal station, the moving spirit of the ministry.

Meanwhile however war had again broken out with France in the preceding June;—in one quarter of the world indeed, in India, the French and English, as allies of the conflicting native powers, can scarcely be said to have ever laid down their arms;—but the new quarrel of the two governments took its rise from a disagreement about the boundaries of their respective possessions in North America, which had been left unsettled by the late treaty. The war, in which all the principal European powers were eventually involved, is known by the name of the Seven Years' War. Its commencement was extremely disastrous to the English, Minorca and Calcutta having both fallen to the French in the summer of 1756. The popular indignation excited by these reverses overset the administration of the duke of Newcastle. Deserted by Mr. Fox, his grace resigned in the beginning of November; and by the end of December, Pitt, who had for some time past attached himself to the court of the young prince of Wales at Leicester-house, was secretary of state, with a cabinet composed of his own friends and those of Lord Bute. The antipathies of the king however, and the intrigues of the duke of Newcastle, overthrew this arrangement in a few months. In April, 1757, Earl Temple, who held the office of first lord of the Admiralty, having been dismissed, Mr. Pitt immediately gave in his resignation. It was some time before anybody could be induced to accept the task of constructing a new cabinet; at last, in the beginning of June, after the country had been for nearly two months without a government, the earl of Waldegrave was appointed first lord of the treasury, with Mr. Fox as secretary of state. This administration lasted only for a few days: the king was then informed that he must seek for other aid. After some further negotiation, Mr. Pitt was before the end of the month recalled and appointed premier, with the office of secretary of state, the duke of Newcastle being made first lord of the treasury, and Mr. Fox paymaster of the forces This arrangement subsisted to the end of the reign. From the moment in which the chief direction of affairs was thus placed in the hands of Mr. Pitt the war was prosecuted with extraordinary vigour and success. In January, 1756, a treaty of alliance had been contracted with Prussia, and an alliance between Austria and France was concluded in May of the same year. The commencement of active hostilities between Austria and Great Britain signalized Mr. Pitt's accession to power. In Germany the enemy were, early in 1758, driven out of Bremen and Verden, which they had overrun the preceding year; soon after, Senegal, Goree, and other possessions of the French on the coast of Africa, were reduced; in 1759 the great victory of Minden, gained (1st August) by Ferdinand, the hereditary prince of Brunswick, drove back the French to the Rhine; by a succession of brilliant successes at sea the French navy was almost annihilated; the victory on the Heights of Abraham, in which Wolfe fell (13th September), all but completed the conquest of Canada; Cape Breton, in the same quarter of the globe, had been already recovered; in the East, Clive had recovered Calcutta (2nd January, 1757), taken Chandernagore (14th March), overthrown the Subahdar of Bengal at the great battle of Plassy (23rd June), and was now engaged in driving the French from every remaining possession they had held in India. In the midst of these successes George II. expired suddenly at Kensington from the extraordinary circumstance of a rupture of the right ventricle of the heart, on the 25th of October, 1760, in the 77th year of his age, and 34th of his reign. His children by his queen, besides those that have been already mentioned, were: William Augustus, born 1721, created in 1726 duke of Cumberland; Mary, born 1723, married 1740 to Frederick, landgrave of Hesse Cassel; and Louisa, born 1724, married 1743 to Frederick V. king of Denmark. He was succeeded by his grandson, George III.

In his sentiments and politics George II. was as much a German as his father, and he persevered throughout his reign in the same system of interference in the affairs of the Continent, professedly with the object of maintaining the balance of power, but really with an especial view to the preservation of the hereditary possessions of his family. Though his Hanoverian partialities however occasioned considerable outcry when the wars in which the country was engaged were unfortunate, all this was forgotten in the splendid successes which at the close of his reign crowned the British arms both by sea and land, and at the moment of his death George II. perhaps enjoyed as much popularity as any prince that ever sat on the English throne. Both morally and intellectually his character seems to have very much resembled that of his father; he is said to have been somewhat passionate, but open, straightforward, and placable, though apt to entertain antipathies of considerable obstinacy, as well as steady in his attachment to those who had once attracted his regard. The only study to which he had any partiality was the art of war, in which he conceived himself to be a great adept. His queen Caroline was a woman of considerable strength of character as well as of cultivated mind, and as long as she lived she exercised great influence over her husband. There was a succession of royal mistresses however in this reign, as well as in the preceding. When George II. was Prince of Wales he fell or professed to fall violently in love with the reigning beauty of the day, Mary, daughter of John lord Bellenden, who was one of the Princess's maids of honour; she however rejected his proposals, and married Colonel Campbell, one of the grooms of his bedchamber, who many years after became duke of Argyle. On this the prince attached himself to Mrs. Howard, who succeeded to her place in the household of his wife, and she long continued to hold notoriously the situation of the king's first female favourite, though her influence, it is said, was never equal to that of the queen. Another of this king's mistresses was Amelia Sophia de Walmoden, who in 1740 was created countess of Yarmouth for life—the last instance of this scandalous abuse of the royal prerogative, and prostitution of the honours of the state.

Of the mass of legislation added to the Statute-book during this reign no very large portion retains any importance at the present day. Among the measures most deserving of notice may be mentioned, the Act 4 Geo. II., c. 26, ordering that all proceedings in courts of justice in England, and in the Court of Exchequer in Scotland,

should be in the English language (two years afterwards extended to Wales); the 8 George II., c. 6, establishing a Registry of Conveyances, Wills, &c., in the North Riding of York; the 8 Geo. II., c. 13, which established a copyright in engravings; the 9 George II., c. 5, repealing the old statutes against witchcraft; the 10 George II., c. 28, prohibiting the acting of any new stage play without permission of the lord chamberlain (this was occasioned by some theatrical ridicule directed against Walpole); the 18 Geo. II., c. 15, separating the surgeons of London from the barbers; the 19 George II., c. 39, entitled an Act for the more effectual disarming the Highlands in Scotland, and for restraining the use of the Highland dress, &c.; the 20 George II., c. 30, allowing persons impeached of high treason to make their full defence by counsel; the 20 George II., c. 43, abolishing heritable jurisdictions in Scotland; the 20 George II., c. 50, taking away the tenure of Wardholding in Scotland, and converting it into Blanch and Feu Holdings [FEUDAL SYSTEM]; the 24 George II., c. 23, establishing the use of the New Style; the 26 George II., c. 2, for purchasing the Museum of Sir Hans Sloane and the Harleian MSS., the foundation of the British Museum; the 26 Geo. II., c. 26, being an act permitting Jews to be naturalized by parliament without taking the sacrament, which however was repealed the following year; and the 26 George II., c. 33, commonly called the Marriage Act.

The national debt was considerably more than doubled in the course of this reign; its amount at the conclusion of the Seven Years' War, in 1763, was nearly 139,000,000*l.*, paying an interest of above 4,850,000*l.* The annual parliamentary grants, which at the beginning of the reign usually amounted to about three millions, or three millions and a half, rose at its close to twelve, fifteen, and at last to nineteen m llions.

The country nevertheless undoubtedly made great progress in wealth and general improvement during the reign of George II. Commerce and manufactures were greatly extended; both the useful arts and those that embellish life found a demand and encouragement that was constantly increasing; and various branches both of literature and science were cultivated with considerable ardour and success. We may refer to the conclusion of Smollett's History for an elaborate and comprehensive survey of what was done in all these departments; some of the names which he enumerates as likely to distinguish the age are now little remembered, but many more, including Sanderson, Bradley, Maclaurin, the two Simpsons, and Hales, in science, and Sherlock, Hoadley, Secker, Warburton, Leland, Thomson, Akenside, Armstrong, Home, Gray, Johnson, the two Wartons, Robertson, Hume, Fielding, and Smollett himself, in literature (not to mention Swift, Pope, and Young, the survivors of a former age), are not likely to be forgotten. To these may be added Mead, Pringle, Hunter, Munro, Cheselden, and Sharp, in medicine and surgery; Arne, Boyce, and Handel (who however was a foreigner), in music; and Ramsay, Reynolds, and Hogarth, in painting.

GEORGE (WILLIAM FREDERICK) III., the eldest son of Frederick Lewis, prince of Wales, was born 4th June, 1738. His mother was Augusta, daughter of Frederick II., duke of Saxe Gotha, born 1719, married to the prince of Wales 25th April, 1736. Their other children were—1, Augusta, born 1737, married 1764 to Charles William Ferdinand, duke of Brunswick Wolfenbüttel, died 1813; 3, Edward Augustus, born 1739, created duke of York 1760, died 1767; 4, Elizabeth Caroline, born 1741, died 1759; 5, William Henry, born 1743, created duke of Gloucester 1764, died 1805; 6, Henry Frederick, born 1745, created duke of Cumberland 1766, died 1790; 7, Louisa Anne, born 1749, died 1768; 8, Frederick William, born 1750, died 1765; 9, Caroline Matilda, born 1751 (four months after her father's death), married to Christian VII., king of Denmark, 1766, died 1774.

On the death of his father, 20th March, 1751, prince George succeeded to the title of duke of Gloucester, but he was created prince of Wales on the 20th of April. His mother, under whose care he remained, soon disengaged herself from, or was deserted by, the leaders of the parliamentary opposition which had gathered around and made a tool of her husband; but the king's habitual dislike to her appears never to have been overcome. It has been asserted that, encouraged by the manner in which the princess was treated by the rest of the royal family, the prince's governor, lord Harcourt, and his preceptor, Dr. Hayter, bishop of Norwich, exerted their influence to prejudice him both against the old friends of his father and against his mother herself. Another account is that the princess was prejudiced against the governor and the preceptor by lord Bute, who now became her confidential adviser. [BUTE, EARL OF.] From whatever cause, lord Harcourt and the bishop resigned their places in December, 1752; the ground which they assigned was that Mr. Stone, the prince's subgovernor (placed in that situation by the ministry), Mr. Scott, another tutor (who had been recommended to the late prince by lord Bolingbroke), and Mr. Cresset (who had been appointed treasurer of the prince's household on the recommendation of his mother), were all concealed Jacobites. Stone, it was affirmed, had about twenty years before actually drank the Pretender's health in public. This charge, in which Dr. Johnson, bishop of Gloucester, and Mr. Murray, afterwards the celebrated lord Mansfield, were also involved, was made the subject not only of an inquisition by the cabinet, but afterwards of a debate in the house of lords. It appears to have rested on little or no good evidence. Ample details of the affair, which excited some inflammation in the public mind at the time, are given in Dodington's 'Diary.' Lord Waldegrave was soon after appointed the prince's governor, and Dr. John Thomas, bishop of Peterborough (afterwards of Salisbury, finally of Winchester), his preceptor; and under their management and the more influential superintendence of lord Bute, matters proceeded without further dissension. The prince was kept by his mother in great privacy, and permitted to associate only with a very small and select circle. Her royal highness seems to have been actuated by good intentions; she was very anxious to preserve her son from the contamination of the fashionable profligacy of the day; and in this respect her method may be allowed to have been successful. But in regard to any thing beyond this, both her own notions and those of the persons in whose hands she placed herself were narrow in the extreme. One of her complaints to Dodington against the bishop of Norwich was that he insisted upon teaching the prince and his brothers logic, 'which, as she was told, was a very odd study for children of their age, not to say of their condition.' Bute indeed appears to have felt the propriety of some political instruction being given to the heir-apparent; but his lordship, although he soon after adventured upon the office of prime-minister, had himself scarcely any practical acquaintance with political matters, and had never even made that department of knowledge his study. Independently therefore of his party prejudices, which gave him a general bias towards what would now be called by most people antiquated and illiberal opinions, he was from mere ignorance of the subject a very unfit director of the political studies of the prince; nor were any of his coadjutors or subordinates much more competent. Their pupil accordingly cannot be said to have ever to the end of his life mastered more than the details and conventional forms of political science. In 1759, when he had attained his majority, the prince took his seat in the house of peers; but there is no record of his having taken any part in the business of the house.

George III. succeeded to the throne on the death of his grandfather, 25th October, 1760. Of his eventful reign of nearly sixty years we can here attempt only a very rapid sketch. On the 8th of July, 1761, the young king surprised his council by the unexpected announcement of his intention to marry the princess Charlotte Sophia, second daughter of Charles Lewis Frederick, duke of Mecklenburg Strelitz. The marriage took place on the 8th of September following. It is understood that in determining upon this union the king had the merit of sacrificing a private attachment to what were deemed considerations of political expediency. Throughout his reign indeed he never showed himself deficient in the strength of character necessary to make every thing else bend to what he held to be the demands of his public position. The youth and unblemished moral character of George III., and the circumstance of his having been born in the country, excited much popular regard and expectation on his accession to the throne. From the first however he did not conceal his anxiety for an end of the war which was then urged with so much national enthusiasm. Lord Bute, who had immediately on the commencement of the reign been admitted into the privy council, and made groom of the stole, was in a few months brought into the ministry, with the design probably of effecting that object. He was made secretary

of state in March, 1761. In the beginning of the following October Mr. Pitt resigned, on finding himself opposed by a majority of the cabinet when he proposed to anticipate the designs of Spain by declaring war against that power. The war with Spain, which he had predicted as inevitable, broke out in January, 1762: but in the beginning of June Bute became premier on the resignation of the duke of Newcastle; and on the 3rd of November the preliminaries of peace between France and England were signed at Fontainebleau. By the treaty of Paris, concluded 10th February, 1763, between Great Britain, France, Spain, and Portugal, this country retained possession of Canada, acquired Florida by cession from Spain, and recovered Minorca, but gave up Belleisle, the Havannah, and all the settlements taken from France in the East Indies. An attempt was made by the opposition to excite dissatisfaction with this treaty, but it was not very successful. Bute however resigned on the 8th of April, not so much, it would appear, in consequence either of any opposition in parliament or any unpopularity out of doors, as from want of support in the cabinet. He was succeeded by Mr. George Grenville, who was for some time however generally looked upon as merely the lieutenant of the retired minister. Mr. Grenville's administration commenced ominously with the famous contest with Wilkes, arising out of the publication of the 45th number of his 'North Briton,' on the 19th of April. This business, and the question of general warrants which was involved in it, occupied much of the early part of the following session of parliament. The close of the same session in April, 1764, was made memorable by the passing of the first resolutions asserting the expediency of imposing certain stamp-duties upon the colonies in America. A bill actually imposing such duties was brought forward the next session, and received the royal assent 22nd March, 1765.

In the meantime however various circumstances had concurred to shake the ministry. In the preceding April the king had been attacked by an illness generally supposed to have been the same mental malady with which he was afterwards visited oftener than once in a more serious form. On his recovery, which took place in a few weeks, he proposed that a bill should be brought into parliament empowering him to appoint the queen or any other member of the royal family to act, in case of his demise, as regent during the minority of his successor. The real author of this proposition was, no doubt, Lord Bute. The ministers had of late attempted to throw off his lordship, but on this occasion they did not venture openly to oppose the king's wish; they only attempted, when the bill was on its way through parliament, to exclude from it the name of the princess dowager of Wales. In this however they were signally defeated; a motion having been made in the Commons that the name of the princess should be inserted, the influence of the court and of Lord Bute were sufficient to carry it against ministers by the large majority of 167 to 37. The rising discontents in America came soon after, still further to embarrass Mr. Grenville and his colleagues. It was not however till after a great deal of negotiation that the king found himself strong enough to give them their dismissal.

At last, on the 10th July, 1765, a new ministry was formed, with the marquis of Rockingham at its head. This ministry, though not without considerable hesitation, repealed the American Stamp Act; the bill to that effect received the royal assent 20th March, 1766, and for the present this measure effectually allayed the disturbances in the colonies. The Rockingham ministry however soon came to an end, partly from inadequate support in parliament, partly from the lukewarmness of the court, chiefly from internal dissensions, if not treachery in some of its members. Soon after the prorogation of parliament in the beginning of June, Mr. Pitt was sent for by the king; and by the beginning of August that gentleman, transferred to the House of Lords with the title of earl of Chatham, was at the head of a new cabinet. It was during this administration that on 2nd June, 1767, Mr. C. Townshend, the chancellor of the exchequer, brought forward that renewed measure of American taxation which eventually led to the independence of the colonies. This is believed to have been Mr. Townshend's own scheme, Lord Chatham, though still the nominal head of the cabinet, being now in such a state of health, and so much at variance with the majority of his colleagues, that it is said he was never even consulted in the matter. Mr. Townshend died suddenly, 4th September, on which Lord North was appointed chancellor of the exchequer, and the ministry from this time came to be generally known as that of the duke of Grafton, who held the office of first lord of the treasury. Lord Chatham at last resigned, 15th October, 1768. With the meeting of parliament in the preceding June commenced the second and much more protracted struggle of the government with Wilkes, occasioned by his return for Middlesex, his expulsion by the House, and his repeated re-election. Meanwhile, the new plan of colonial taxation had thrown all English America into commotion as soon as it was announced. The beginning of the next year, 1769, was distinguished by the appearance of the first of the celebrated 'Letters of Junius,' the most effective series of political attacks ever directed against a ministry. The duke of Grafton, the object of the most envenomed shafts of this invisible assailant, suddenly resigned, 28th January, 1770. On this Lord North became premier, and began his administration with a bill, brought in 5th March, for the repeal of all the lately imposed American duties, except the duty on tea, which was retained avowedly merely to assert the right of taxation. This exception however produced the war with the colonies, and their eventual separation. A dispute with Spain about the possession of the Falkland Islands occupied attention for a short time in the latter part of this year, but was eventually adjusted without leading to hostilities. The session of parliament which terminated 8th May, 1771, is memorable for the successful assertion by the newspaper press of the right of reporting the debates, after a contest with the House of Commons, which lasted from the beginning of February to the end of April, and for two months of that time almost wholly occupied the House. This and the following year were also marked by some important events in the royal family. In the summer of 1771, the king's third brother, the duke of Cumberland, married Mrs. Horton, daughter of Lord Irnham (afterwards earl of Carhampton), and widow of Christopher Horton, esq. His Majesty, as soon as the affair was publicly announced, forbade the duke and duchess to appear at court; but this did not deter his second brother, the duke of Gloucester, from avowing, a month or two afterwards, his marriage with the countess dowager of Waldegrave (daughter of Sir Edward Walpole), which had taken place six years before. The Royal Marriage Bill was in consequence brought into the House of Lords, and, notwithstanding a strenuous opposition, passed into a law. By this statute (12 Geo. III. c. 11) all descendants of George II. (except the issue of princesses married into foreign families) are prohibited, while under the age of twenty-five, from contracting marriage without the consent of the king, and without the consent of parliament if above that age. The king's mother, the princess dowager of Wales, died on the 8th February, 1772. Only a few days before had occurred at Copenhagen the catastrophe of the king's youngest sister, the queen of Denmark, who was suddenly thrown into confinement by order of her imbecile and dissolute husband, on a charge of adultery with his physician Struensee. No proof of the criminality of the parties ever was produced, though both Struensee and his friend Brandt were put to death without trial. The queen was sent in the first instance to the castle of Cronsburg; but after being confined there for about four months, the interposition of her brother procured her release, and she was conveyed first to Stade, and afterwards to Zell, in Hanover, where she lived in retirement till her death, 10th May, 1774.

The disturbances in America, excited by the tea duty, broke out in the summer of 1773. The Gaspee schooner was attacked and burned at Providence in Rhode Island, in June: the destruction of the tea by the mob at Boston took place in December. Another year however was spent before the quarrel assumed the character of a regular contest of arms. Hostilities commenced with the battle of Lexington, 19th April, 1775; that of Bunker's Hill followed, 16th June. Still the resistance of the colonists had not taken the form of an avowed determination to throw off the dominion of the mother-country. It was not till the ever memorable 4th of July, 1776, that the contest was brought to this point by the Declaration of Independence. In the course of the next year many French officers joined the Americans, and it became evident that the governments both of France and of Spain were about to take part publicly with the revolted colonies. Meanwhile, on the 16th of October, the conven,

tion of Saratoga, and the surrender of Burgoyne, inflicted the first great blow upon the British cause. On the 6th February, 1778, a treaty was signed between the Americans and France, in which the independence of the former was acknowledged. War between England and France of course immediately followed this act. In June, 1779, Spain too at last openly joined the hostile confederacy; and before the end of another year England had found still another enemy in Holland. The convention of the northern powers of Russia, Denmark, and Sweden, (soon after joined by Holland, Prussia, and the Emperor,) for the maintenance of what was called the armed neutrality—being in fact a defiance of the power of Great Britain to enforce the commonly recognised rights of belligerents—was also established in the course of the year 1780. At home this was the year of the Protestant riots, when London was for nearly a week in the hands of a devastating mob, which was not put down till after a great effusion of blood, as well as destruction of property. The popular mind in Ireland moreover was in a state which occasioned the greatest alarm; the inhabitants were embodied as volunteers to the number of fifty or sixty thousand, and the British parliament had already in the beginning of this year been compelled to yield to some, and was soon to be forced to concede more, of the demands of these petitioners with arms in their hands.

Meanwhile the nation was becoming heartily tired of the war; and the ministry, surrounded by so many embarrassments, stood at the lowest point of unpopularity. These feelings continued to increase in the public mind, as new failures and calamities further demonstrated the incapacity or the ill luck with which the affairs of the country were conducted. Even in the East, where the French had at the commencement of the war been again driven from all their settlements, the successes of Hyder Ali now seemed to be fast changing the face of affairs. In America the surrender of Lord Cornwallis at Yorktown, on the 19th October, 1781, in effect terminated the struggle. Lord North and his colleagues resigned on the 20th March, 1782, on which the marquis of Rockingham was once more placed at the head of a new ministry; but his death about three months after his acceptance of office again overthrew all the arrangements that had been made. Lord Shelburne having succeeded to the place of first lord of the treasury and premier, Mr. Fox and all his friends immediately resigned. Among the new appointments was that of Mr. Pitt to the office of chancellor of the exchequer, in the room of Lord George Cavendish. It is said to have been by the persuasions of Lord Shelburne that the king was at last, after extreme reluctance, prevailed upon to consent to acknowledge the independence of the colonies. The preliminaries of a peace were signed at Paris on the basis of that acknowledgement on the 30th November; and on the 3rd September, 1783, the war, which had resulted in so large a curtailment of the dominions of the British crown, was formally brought to a close by the signature of definitive treaties with America, France, and Spain. Peace with Holland was also concluded at Paris, 20th June, 1784.

In the mean time however the famous coalition between the followers of Mr. Fox and of Lord North, parties which had been so long and so bitterly opposed, had succeeded in the beginning of April, 1783, in driving Lord Shelburne and his friends from power. Lord North and Mr. Fox now became secretaries of state together, with the duke of Portland as first lord of the treasury and nominal premier. This arrangement however was soon overthrown. The new cabinet was exposed from the first to a storm of public outcry, and this greatly aided the determined efforts of the crown to shake itself free from a ministry that had been forced upon it. The only strength of the coalition indeed lay in the existing House of Commons The defeat of Mr. Fox's India Bill in the House of Lords by the private exertion of the influence of the crown, 17th December, on the question of going into committee, was followed the next day by the dismissal of both Fox and North, and the immediate appointment of a new ministry with Mr. Pitt at its head. The contest of parties which ensued is the most memorable in the annals of parliament. It was only terminated by the dissolution of the parliament 24th March, 1784, and the overwhelming majority of supporters which the result of the elections gave to the court and the ministry in the new House of Commons. Throughout this long and violent struggle, Mr. Pitt's own firmness and resolution were seconded by the steady support of the king, who is said to have openly declared his determination, rather than receive back Mr. Fox as minister, to resign his crown and retire to Hanover.

The formidable front presented by the Irish volunteers in the season of the national difficulties and disorders had extorted from the British parliament, in 1782 and 1783, the repeal of the restrictive statute of 1720 [George I.], and the acknowledgment (by the 23 Geo. III., c. 28) of the complete independence of the parliament of Ireland. Both in Ireland and in England the agitation of the question of parliamentary reform occupied public attention for some time after the conclusion of the war; but it was productive of no results. On the 2nd of August, 1786, an attempt was made upon the king's life by a mad woman named Margaret Nicolson, who struck at him with a knife as he was alighting from his carriage at St. James's, but missed her aim. In November, 1788, his majesty was visited with a second and more serious attack of illness, which was admitted to be delirium, and from which he did not recover till the following March. On this occasion Mr. Fox and his friends contended that the powers of the government devolved as of right upon the Prince of Wales; but parliament stood by Mr. Pitt in his opposition to that doctrine, and a bill conferring the regency upon the prince with certain restrictions had nearly passed both houses when the king recovered. The parliament of Ireland in the mean time had made use of their lately acquired independence to offer the prince the government of that kingdom, without any restrictions. As the prince had attached himself to the party of which Mr. Fox was the head, expectations of important political changes were excited by the prospect of his royal highness becoming the head of the state.

The quiet which had for some years reigned in Europe was broken in 1789, by what soon became the all-absorbing subject of interest, the Revolution in France. The history of the remainder of the reign is chiefly that of the share borne by England in the wars which grew out of that great convulsion. Whatever may have been the inclination of the court, there can be no doubt that Mr. Pitt was reluctantly drawn into the war with France. The demand however that the country should take up arms was loudly made by the large section of the whig body, which, with Mr. Burke for its soul, went over to the ministry in 1792 and 1793; and this was also decidedly the general voice of the country. In point of fact, war was at last declared, not by England but by France, 1st February, 1793, a few days after the execution of the French king.

The general course of the war, almost from its commencement to its close, has already been sketched in the article Bonaparte. We shall here merely enumerate in their chronological order the principal events more immediately belonging to English history. Conventions were immediately made for carrying on operations against France with Naples, Sardinia, Prussia, the Emperor, Hesse-Cassel, Baden, Hesse-Darmstadt, Brunswick, and by George III. with himself in his capacity of Elector of Hanover. A treaty of mutual alliance with Holland already subsisted. Spain and Portugal also immediately became parties to the war. Finally Russia still professed to adhere to the combination against France, though the real object of the Empress Catherine was merely the partition of Poland, which she soon after effected in association with Austria and Prussia. The first military measure of the British government was to send a force to Holland under the command of the duke of York. In the campaign of 1793 the French were expelled from Flanders by the Austrians; and the allied army under the prince of Saxe-Coburg and the duke of York took Valenciennes and Condé. The duke however was afterwards repulsed with great loss in an attempt upon Dunkirk. Toulon was taken possession of by Lord Hood, but speedily recovered by the French. In 1794 the French fleet was signally defeated by Lord Howe in the Channel on the 1st of June; the English also became masters of Corsica. In 1795 the islands of Martinique, St. Lucia, and Guadaloupe in the West Indies, were taken from the French; Guadaloupe however was soon after retaken. The people of Holland now drove out the stadtholder, and with the assistance of the French established what was called the Batavian Republic; on this the Cape of Good Hope, Ceylon, and other Dutch possessions in the East Indies were seized by England. Peace was made with France by Prussia, 5th April, and by Spain, 22nd of July. In 1796 the English were compelled to withdraw

from Corsica; on the 5th of October Spain declared war against England; in the latter part of the same month an ineffective attempt was made to open negotiations for peace by the mission of Lord Malmesbury to Paris; in December an attempt of the French to make a descent upon Ireland was defeated by a storm which dispersed the invading fleet, having a force of 15,000 men on board, only two ships reaching the neighbourhood of Bantry Bay, which they left in a few days. The military events in which the British arms were concerned in 1797 were, the defeat of the Spanish fleet off Cape St. Vincent by Sir John Jervis, 14th February; the capture from the Spaniards of Trinidad, Porto Rico, and Teneriffe; and the great victory obtained by Lord Duncan over the Dutch fleet off Camperdown, 11th October. Peace with France having been made by Austria in April, another attempt at negotiation was made by the English government in the course of the following summer, Lord Malmesbury having been sent to meet the French plenipotentiaries at Lisle; but it ended in nothing. This was also the year of the suspension of cash-payments by the Bank of England, 27th of February—and of the mutiny in the fleet at Spithead in April, and at the Nore in June. The great domestic event of 1798 was the rebellion in Ireland, organized by the society of United Irishmen, which broke out in the end of May, and was not finally suppressed till the end of September. A small French force landed at Killala on the 22nd of August, and penetrated a considerable way into Connaught, but surrendered after a sharp contest to a detachment of the army of Lord Cornwallis, on the 11th of September. On the 1st of August this year Nelson gained his great victory of the Nile. In 1799 a new confederacy having been formed against France, to which Austria, Russia, Naples, and Turkey were parties, an English army was sent to the Netherlands under the command of the Duke of York, but it was soon compelled to evacuate the country. On the 4th of May, Tippoo Saib, the Sultan of Mysore, who had entered into alliance with the French, was defeated and killed, and his capital of Seringapatam taken by Sir David Baird, on which the greater part of his dominions was added to the English territory. In August Surinam was taken from the Dutch, whose ships of war also in the course of this year almost all fell into the hands of the English. Minorca and Malta were taken by the English in the course of the year 1800.

Notwithstanding these and other partial successes however, the heavy pecuniary exactions of the war, together with its evident failure in so far as respected an advance towards the attainment of any intelligible ultimate object, and the steady progress of the French arms in the subjugation of the Continent, had now wearied and worn out the enthusiasm even of the greater number of those who had been originally its most ardent supporters. By a considerable part of the nation the contest had come to be regarded with feelings of the bitterest aversion. The inflamed temper of the populace, excited in part by the notion which very generally possessed them, that the real object of the war in which the country was engaged was the repression of democracy and liberty both at home and abroad, had, among other excesses, led to an attack upon the king by the mob as he passed through the park in going to and returning from the House of Lords at the opening of the session of parliament on the 29th October, 1795. The feelings however which vented themselves in this manner were never participated in by any considerable portion of the community; the sentiment of the great majority of all classes of the nation was certainly, throughout the reign, one of kindness and respect towards his majesty, with which, in most cases, even strong political dissent from the general course of his government did not much interfere. The affection that was entertained for the king personally was remarkably shown by the numerous addresses of congratulation that were presented from all parts of the kingdom on his escape from the attempt of a maniac named Hatfield, by whom he was fired at with a pistol from the pit of Drury Lane Theatre, on the 15th May, 1800. In the spring of 1801 his majesty had another slight attack of his mental malady.

The important measure of the union of Great Britain and Ireland was after many difficulties at last effected in 1800. This event led, in March, 1801, to the resignation of Mr. Pitt, who now considered himself pledged to the removal of the Catholic disabilities, to which however the king firmly refused his assent. A new ministry was in consequence constructed, with the Rt. Hon. Henry Addington (afterwards Lord Sidmouth) at its head. Immediately before these events a rupture had taken place with Russia, and that power had united with Sweden and Denmark in the establishment of a new armed neutrality. The death of the Emperor Paul however soon led to a reconciliation between England and the three northern kingdoms. Meanwhile, on the 2nd April, Copenhagen was bombarded, and the Danish fleet partly taken, partly destroyed, by Nelson. In the East also, this year, the victory of Alexandria was gained over the French, with the loss of the gallant Sir Ralph Abercromby, on the 21st March; and on the 2nd September, Alexandria surrendered to Lord Hutchinson, and the French were compelled to evacuate Egypt. In the beginning of October it was unexpectedly announced that negotiations which had been for some time in progress had terminated in the signature of the preliminaries of a general peace. This news was received with universal satisfaction and rejoicing. The definitive treaty of peace was signed at Amiens, 25th March, 1802.

Within a year however hostilities were renewed. The course of the war from this period must be fresh in the recollection of many of our readers; we need only notice as its most remarkable occurrences, in so far as this country was concerned, the occupation of Hanover by the French, in 1803; the declaration of war by Spain, in December, 1804; the threatened invasion by France, and Nelson's glorious victory of Trafalgar, in 1805; the unsuccessful attempts to negotiate a peace, the capture of the Cape of Good Hope by England, and Bonaparte's Berlin Decree [BLOCKADE] of 1806; the seizure of the Danish fleet and the capture and subsequent evacuation of Buenos Ayres, in 1807; the insurrection in Spain, the alliance entered into with that country, and the expulsion of the French from Portugal, in 1808; the long contest begun in that year, which eventually achieved the liberation of the peninsula; the war with America, in 1812; the treaty with Russia, in that year; the treaties with Sweden and Austria, and the expulsion of the French from Hanover, in 1813; the peace with Denmark, in January, 1814; the surrender of Paris to the allies, in March; the abdication of Bonaparte and restoration of the Bourbons; the peace with America, signed at Ghent, in December; the return of Bonaparte from Elba, in March, 1815; and finally, the victory of Waterloo, in June following, which put an end to the war.

Of the public events which occurred within the kingdom during this period the most remarkable were:—the return of the king's illness for a few weeks in February, 1804; the restoration of Mr. Pitt to power, in May of that year; the death of Mr. Pitt, 23rd January, 1806; the accession of the ministry of Mr. Fox and Lord Grenville; the death of Mr. Fox, 13th September; the dissolution of the Grenville administration, in March, 1807, in consequence of the king refusing his assent to their proposed measures for the relief of the Roman Catholics; the formation of a new cabinet under the duke of Portland and Mr. Percival; the resignation of the command of the army by the duke of York, in March, 1809, in consequence of the result of an investigation on charges of corrupt practices (of which however it appeared that the profits were reaped, not by the duke, but by his mistress, the notorious Mrs. Clarke); the celebration, on the 25th October, that year, of the Jubilee, on the occurrence of the fiftieth anniversary of his majesty's accession; the commencement of the final insanity of the king, in the end of October, 1810; the consequent appointment, by act of parliament, of the prince of Wales as regent, in February, 1811; the assassination of Mr. Percival, 11th May, 1812; and the appointment of the earl of Liverpool as premier. The ministry of Lord Liverpool lasted during the remainder of the reign. The king continued in the same state of mental incapacity into which he had fallen, till his death at Windsor Castle on the night of Saturday, the 29th January, 1820, in the eighty-second year of his age and the sixtieth of his reign. He had been entirely blind for some years before his death.

For an enumeration of the children of George III. and Queen Charlotte (who died at Kew, 17th November, 1818) we refer to any of the Almanacs or Peerages. They were fifteen in all, namely, nine sons (of whom two, George, his successor, and William, have already reigned, and three are still living), and six daughters, four of whom are living.

On the subject of the character, moral and intellectual, of

George III. there is probably now not much difference of opinion. He had no pretensions to any superior penetration or vigour of understanding, but he possessed rather more than the ordinary endowment of practical tact and skill in the management both of affairs and of men. He was perfectly master of all the proprieties of his station, which never, at least on important occasions, lost any of its respectability or authority during his occupation of it. His firmness or tenacity of purpose was such as usually to defeat in the end any attempt that was made to thwart his wishes in the movements of domestic politics, and indeed it was generally believed that the royal spirit of determination or obstinacy had a considerable share in prolonging more than one of the great public contests in which the country was involved during this reign, after all reasonable hope of success had vanished. But it has generally been admitted that the persistency of George III., however mistaken or unfortunate, was for the most part conscientious—in other words, that he firmly believed himself to be in the right even in those cases in which he was possibly most in the wrong. The credit that was given to him upon this point operated with a powerfully favourable effect not only upon the estimation in which he was personally held, but in obtaining support to the measures of his government. The decorum of his private conduct also was of much service to him, as well as probably efficacious in no slight degree in giving a higher tone to the public manners and in making the domestic virtues fashionable even in the circles where they are most apt to be treated with neglect. It ought not moreover to be omitted, that, with whatever narrowness of view consequent upon his training and his position George III. may be chargeable, he was—what many influential persons of his time were not—an avowed friend to the diffusion of education, and certainly was not afraid that his subjects would be made either more difficult to govern or worse in any other respect, by all classes and every individual of them being taught to read and to write.

It is scarcely necessary to observe that over all our Western world, and nowhere more than in England, the period forming the reign of George III. is perhaps to be placed above every other of the same length in modern history for the multitude and vastness both of the social changes and of the accessions to almost every department of human knowledge by which it has been signalized. It is worth remarking however that even the political confusion and universal wars of the latter half of the period did not prevent that space from being at least as productive of valuable inventions and discoveries, and as distinguished for the busy and successful cultivation of every branch of science and literature, as the quieter time that preceded.

Very great changes took place in the extent of the British dominions during the reign of George III. Ireland ceased to be a separate kingdom—Hanover was lost and recovered—Canada was added to our colonies—our other and much more important possessions on the North American continent were severed from us—a new empire, immense in its extent and population, was acquired in India. On the whole, notwithstanding the loss of the American colonies, the power and influence of the state were undoubtedly much greater at the close of the reign than they were at its commencement. Of the commerce and wealth of the country it would be more correct to say that they were multiplied during this period than simply that they were increased. No financial operations were ever effected or undertaken or dreamt of in any other time or country approaching to the gigantic magnitude of those accomplished by the British government in the closing years of the late war. The revenue raised by taxation at the beginning of the reign was under nine millions; it did not reach ten millions till the year 1773; in 1780 it had increased to somewhat above twelve millions; in 1786 it was fifteen millions; in 1793, at the commencement of the war with France, it was seventeen millions. After this new taxes were imposed to a considerable amount, so that the entire revenue raised in 1800 exceeded thirty-four millions.* From this date it continued to rise every year, till, in 1815, it amounted to the immense sum of 72,210,512*l.* In the seven years from 1810 to 1816 inclusive, about 472,000,000*l.* were raised by taxes alone, being on an average above 67,000,000*l.* per annum. In 1819, the last year of the reign, the sum thus raised was still nearly 53,000,000*l.* The sums raised by loans were, to the end of the Seven Years' War in 1763, about 32 millions; during the American war (1775-1784) above 121,000,000*l.*; and during the last war with France (1793-1815) above 609,000,000*l.* In the year 1813, the total amount borrowed was 52 millions funded, and above 55½ unfunded, making, with the produce of the taxes, the total payments into the Exchequer for that year 107,597,660*l.*, being at the enormous rate of above two millions weekly. The national debt, which at the commencement of the reign was about 108,000,000*l.*, on which was paid an annual interest of not quite 4,000,000*l.*, had increased by the end of the reign to above 800,000,000*l.* of principal, bearing an interest of more than 30,000,000*l.*

The collection of the Statutes passed in the reign of George III. is nearly four times as large as that of the whole mass of preceding English legislation from the Conquest. We can only here mention, as having most of a popular or historical interest,—the Act of 1761, continuing the commissions of the judges notwithstanding any demise of the crown—the Royal Marriage Act already noticed—the Grenville act of 1770 (amended in 1788) for the settlement of disputed elections of members of the House of Commons—the act of 1782, disqualifying revenue officers from voting at elections, and government contractors from sitting in the house—the act of 1792 (commonly called Fox's Libel Law), declaring the right of juries to judge of the law as well as of the fact in cases of libel—the act of 1801, excluding clergymen from the House of Commons—the act of 1807, abolishing the Slave Trade—Sir Samuel Romilly's acts of 1811 and 1818, for the amelioration of the criminal law—the act of 1813, abolishing the penalties and incapacities to which Unitarians were formerly subjected—the act of 1819, abolishing the appeal of battle in cases of murder—the foreign enlistment act, of the same year—and the acts of that year, for the suppression of blasphemy and sedition, commonly called the Six Acts.

GEORGE (AUGUSTUS FREDERICK) IV., king of Great Britain, the eldest son of George III., was born 12th August 1762, exactly 48 years (making allowance for the difference of style) after the accession of the House of Hanover. On the 17th he was created by letters patent prince of Wales and earl of Chester, and was baptized the next day. He was made a knight of the garter, 26th December, 1765, and a few months afterwards was appointed by a king's letter, addressed to the lord mayor, captain-general of the Honourable Artillery Company of the city of London. The prince of Wales was educated along with his next brother Prince Frederick, bishop of Osnaburg (afterwards duke of York) in great privacy, and on a system of strict discipline.

In April, 1771, Lord Holdernesse was appointed governor; Mr. Smelt, sub-governor; Dr. Markham, bishop of Chester (afterwards archbishop of York), preceptor, and Mr. (afterwards Dr.) Cyril Jackson, sub-preceptor to the two princes. In 1776 however all these persons suddenly resigned their offices, for some cause which has never been satisfactorily explained. The common account is, that they found some political works which they considered objectionable put into the hands of the boys by the directions of the king. Their successors were, for the first few days, Lord Bruce (immediately afterwards created earl of Aylesbury), and then the Duke of Montague, as governor; lieutenant-colonel Hotham as sub-governor; Dr. Hurd, bishop of Lichfield and Coventry (afterwards of Worcester), as preceptor; and the Rev. William Arnold, as sub-preceptor. The prince, notwithstanding murmurs and remonstrances, of which notice began to be taken in the public prints, was kept by his father in a state of unmitigated pupilage till he was nearly eighteen, his seclusion being divided between Buckingham House, Kew, and Windsor. It was not till the year 1780 that the princes began to appear much in public. From this time the life of the prince of Wales for many years belongs for the most part to the *Chronique Scandaleuse* but among the various persons of both sexes with whom he was connected, there are a few names that may be said to have already become historic, and that cannot altogether be passed over. The first of his many con-

* We take this last sum and those that follow from the 'Official Tables' of the Board of Trade, part iii., p. 1. But the diversity of statement among the several authorities on these subjects is very great. According to Sir John Sinclair ('History of the Public Revenue,' 3rd edit. ii., 132, 133) the produce of the old and new taxes for 1800 was only a little above 26 millions. Colquhoun ('Wealth, &c. of the British Empire,' p. 198) makes the amount between 29 and 30 millions. These two statements will nearly agree with each other, and also with that of Macpherson ('Annals of Commerce,' iv., 508, 509), if we suppose the revenue of Ireland to be excluded from the first and included in the second.

nexions of a similar nature that became notorious was with Mrs. Mary Robinson, then an actress and the wife of an attorney. This lady (whose maiden name was Darby, whose early years were superintended by Mrs. Hannah More, who in the latter part of her life became the mistress of Colonel Tarleton, and died at Englefield Green, at the age of forty-two, in 1800, after having made herself well known by her novels and verses, as well as by her adventures) has told her own story in her own way in her 'Memoirs,' published after her death by her daughter. She was four years older than the prince, and already of damaged reputation, when she first caught his attention, in 1780, while acting Perdita in the 'Winter's Tale;' her influence lasted for not quite two years

In December, 1780, on the departure of the bishop of Osnaburg for Germany, where he remained for seven years, a separate establishment on a small scale was formed for the prince; and having now become legally his own master, he was from this time much in the public eye. It was now that he entered upon his intimacy with Charles Fox, Sheridan, and other leaders of the whig party, who happened accidentally to be also among the most distinguished patrons of the fashionable gaiety and licence of the day; one of the persons also with whom he formed the closest friendship about this time was the afterwards notorious duke of Orleans, then styled the Duc de Chartres, who paid long visits to London in 1783, and several following years. With these associates the prince indulged without restraint his propensities for gambling, horseracing, and other kinds of extravagance and dissipation. He also adopted warmly and openly the politics of his whig companions, and this at once placed him in direct opposition to his father's government. In April, 1783, however, his friends, under the name of the Coalition Ministry, forced themselves into power, and on the opening of parliament, on the 11th of November following, the prince of Wales was introduced with great ceremony into the House of Lords as Duke of Cornwall, and took his place among the supporters of the new administration. They had, immediately after entering upon their places, laid before the king the claims of the prince for an augmented establishment and allowance. The ministers demanded 100,000*l.* a year, but the king would not consent to more than 50,000*l.*, with an allowance of 60,000*l.* as an outfit: the prince had besides about 14,000*l.* a year as Duke of Cornwall. At the same time Carlton House was assigned to him as a residence. He stood by his friends on their expulsion a few months afterwards, notwithstanding some endeavours, it is said, on the part of his father to detach him, and took an active part in the private movements that were entered into without success for their reinstatement. In 1786 the subject of the prince's pecuniary embarrassments, which had become extremely pressing, was first mentioned in the House of Commons by his friend Sheridan, and this led to a negotiation with the king, who however, after keeping expectation in suspense for some time, finally refused to sanction any measures of relief. In these circumstances the prince resolved to break up his establishment, and to limit his expenditure to 5000*l.* a year, reserving the rest of his income for the payment of his debts. It was a short time before this that he had formed the most celebrated and lasting of his female attachments. Mrs. Fitzherbert, whose maiden name was Smith, was the daughter of a Catholic gentleman of Shropshire, and had been married first to Mr. Weld of Lulworth Castle, and secondly to Colonel Fitzherbert, who also died within a year after their marriage. She was still young and beautiful when the prince first saw her, in 1781; he immediately declared his passion, on which she went to the Continent, it is said, to avoid his importunities; but she returned in 1784, and soon after their connexion became generally known. All the circumstances of this affair have never been distinctly made public; but it would appear that Mrs. Fitzherbert considered herself as united to the Prince by marriage, and that this assumption was generally recognised by society, in which she certainly retained her place till her death, only a few years ago; even the subsequent marriage of the prince with another person not being held, it seems, to affect her pretensions, any more than the royal marriage act, according to which his marriage with her, in whatever circumstances it took place, could not have been legal. But the point which occasioned the greatest public outcry was the fact of Mrs. Fitzherbert being a Catholic, and, as such, a person by marrying whom the prince by the Act of Settlement would have become incapacitated to inherit the crown. The state of the prince's pecuniary affairs was again brought before parliament in April, 1787, by Alderman Newnham, one of the members for London; and on this occasion Mr. Fox came down to the house, and, on the express authority of the prince, characterized the supposed marriage with Mrs. Fitzherbert as a thing which not only had not happened, but which was even impossible to have happened. To a farther question he answered, 'That he denied the calumny as false *in toto*, in every sense of fact as well as law:' he added that he spoke from direct authority. There can be no question that Mr. Fox had been made to believe that not even any ceremony of marriage had ever been performed. It is said that Mrs. Fitzherbert, upon learning what had taken place, insisted, as the condition on which she would consent again to see the prince, that Mr. Fox's declaration should be as publicly and authoritatively retracted as it had been made: but it was found, after some attempts, that this could not be managed; and the lady soon afterwards yielded the point. She would never however speak to Mr. Fox again, who also complained strongly of the equivocating manner in which the prince expressed himself on the subject. The intimacy between the prince and Mrs. Fitzherbert continued without interruption till the summer of 1794; it was then suddenly broken off, but was a few years afterwards renewed.

The further parliamentary agitation of the prince's pecuniary difficulties in 1787 was prevented by the king at last giving his consent to a grant of 160,000*l.* for the payment of his son's debts, and of 20,000*l.* for completing the repairs of Carlton House. Both these sums were greatly inadequate, but the arrangement afforded some relief for the moment, and enabled the prince to resume his former state and habits of life. The king's illness, in the close of the year 1788, and the proceedings that took place in regard to the proposed regency, have been noticed in the preceding article. Upon this occasion Mr. Fox asserted that the 'exercise of the royal power was the clear right of the heir apparent, being of full age and capacity, during the king's incapacity;' but he afterwards admitted that 'the heir apparent had no right to *assume* the executive power,' and that, although the right was in the prince,' it was subject to the adjudication to him of its possession and exercise by the two houses.' It may be doubted how far his position was strengthened or made more intelligible by this qualification. On the king's recovery, both he and the queen chose to show themselves deeply offended with the conduct of the prince during his father's illness—although no distinct charge of undutifulness appears ever to have been alleged. A reconciliation however was effected about the beginning of the year 1790, through the interposition, it is understood, of Lord Thurlow, who had his own ends to serve. The king however would not consent to relieve the prince from his fast increasing embarrassments by another application to parliament, except upon the one condition, that he would marry.

It was in the summer of 1791 that a transaction occurred which made a great noise at the time and long afterwards,—the retirement of the prince from the turf, in consequence of the decision of the Jockey Club, that he must either take that step or dismiss a servant whom they held to be guilty of unfair management in relation to a particular race with one of his master's horses. The character of the tribunal is such as not to entitle us to draw from this decision any conclusion unfavourable either to the prince or his servant; the former had only a few hundred guineas depending on the race; and the circumstances seem to make it altogether improbable that either was guilty of the foul play imputed. The prince stood by his servant and settled on him an annuity of 200*l.* a-year. He soon after sold off all his horses, to the number of 500, and again retrenching his expenses and shutting up Carlton House, devoted the greater part of his income to the payment of his creditors. He now also publicly separated himself from Mr. Fox and his party by a speech in the House of Lords, the first he had ever delivered, 31st May, 1792, in which he declared his adherence to that section of his party which had gone over to the minister, in the division which had taken place on the subject of the French Revolution. He afterwards took a formal leave of his old friends in a letter addressed to the Duke of Portland.

At length in the summer of 1794, the prince, borne down by the heavy and rapidly augmenting load of his incum

brances, yielded to the demand so long urged by his father, and consented to marry. His unfortunate marriage with his cousin, Caroline Amelia Elizabeth, second daughter of the Duke of Brunswick and the princess Augusta, [GEORGE III.], took place on the 8th of April, 1795. On this his income was raised to 115,000*l.* a-year, 25,000*l.* being deducted from that sum for the payment of his debts, which according to the statement made to parliament amounted to about 650,000*l.* Disgust and alienation, as is well known, soon followed between the newly-married parties. So early as the beginning of June, the princess demanded the removal of Lady Jersey, who was one of her ladies in waiting; this the prince positively refused: the birth of a daughter, the late Princess Charlotte Augusta, on the 7th of January, 1796, produced no return of affection; they continued to live for some months longer under the same roof, but without speaking to each other; a complete separation then took place, the princess retiring with her infant, first to the village of Charlton, near Greenwich, and afterwards to Blackheath.

There are no events requiring much notice in the prince's history for some years after this. He frequently solicited his father to give him a military appointment, and a short time before the breaking out of the rebellion of 1798 he requested, it is said, to be allowed to undertake the chief government of Ireland; but all these petitions met with a determined refusal. About this time also he partially renewed his connection with Mr. Fox and his old friends—but it was now more an association of conviviality than of politics. The prince came nevertheless to be popularly considered as again the head or rallying-post of the whig party; and on that and other accounts the estrangement between him and his father soon became as complete as before. His conduct to the Princess of Wales was viewed by the king with the deepest displeasure. In these circumstances it naturally happened that the tories at this time clung to the princess, as their opponents did to her husband. Such was the political situation of the parties when the first investigation into the conduct of the princess took place in the latter part of the year 1806, by a commission constituted by royal warrant, and consisting of the late Lords Erskine, Grenville, Spencer, and Ellenborough, all then members of the cabinet. The allegations which led to this investigation proceeded from Sir John and Lady Douglas, who charged her royal highness not only with great impropriety and indecency of behaviour, but with having been delivered in 1802 of a male child, whom she had ever since brought up and retained near her under the name of William Austin. The report of the commissioners decidedly acquitted her royal highness on the latter and main charge; but added that there were other particulars deposed to by the witnesses examined respecting her conduct, 'such as must, especially considering her exalted rank and station, necessarily give occasion to very unfavourable interpretations.' The report however, and the answer of the princess (drawn up by her confidential advisers, Lord Eldon, Mr. Perceval, and Sir Thomas Plumer), together with other papers, having been afterwards submitted to the cabinet council (the whigs were now out of office), it was declared by a minute dated 22nd April, 1807, to be the unanimous opinion of the members not only that the two main charges of pregnancy and delivery were completely disproved, but 'that all other particulars of conduct brought in accusation against her royal highness, to which the character of criminality can be ascribed, are satisfactorily contradicted, or rest upon evidence undeserving of credit.' With the exception of these decisions, all the proceedings in this affair were kept secret for some years; but the depositions of the witnesses and the other papers were at length surreptitiously published in 1813, in the well-known volume entitled 'The Book.' The history of the investigation into the conduct of the princess is in all its stages curiously illustrative of the movements and changes of position of the two great political parties; she was condemned or acquitted by the official reporters upon her conduct, according as the party to which her husband attached himself or their opponents happened to be in power, and her cause was taken up by either as the prince bestowed his favour upon the other.

On the king being taken ill in the end of 1810 the prince of Wales was in the first instance appointed regent, with restricted powers, and for only one year. He entered upon his office by being sworn in before the privy council, 3rd February, 1811. The restrictions however were removed in the beginning of the following year. On thus becoming king in every thing but in name, the prince disappointed the expectations of a great part of the public by retaining Mr. Perceval and the other ministers whom he had found in office on assuming the direction of the government. In fact no change in the policy of the government was produced by the regency; the prince threw off at once both his former associates and their principles. It is unnecessary to recount, except very cursorily, the events of a period so recent that every reader must be supposed to possess a more complete knowledge of its history than we can here attempt to supply. The course of public occurrences down to 1820 has been shortly noticed in the preceding article. In the beginning of 1813, the unhappy differences between the prince and his wife again became the subject of parliamentary and public discussion, in consequence of the publication by the latter in the newspapers of a letter which she had addressed to the prince, remonstrating against some steps that had been taken in relation to the princess Charlotte. Upon that occasion the privy council, on the matter being submitted to them by the prince, reported that under all the circumstances of the case it was highly fit and proper 'that the intercourse between her royal highness the princess of Wales and her royal highness the princess Charlotte should continue to be subject to regulation and restraint.' Her former friends, the tories, had now completely abandoned the cause of the princess of Wales; the second name attached to this report was that of her recent confidential adviser Lord Eldon. The publication of 'The Book' immediately followed. In 1814 the visit of the emperor of Russia and king of Prussia to London, after the peace of Paris, led to renewed exposure and agitation, by the regent refusing to meet the princess at the drawing-room held by the queen for the reception of the foreign sovereigns. In resentment for her exclusion on this occasion, her royal highness left the country in the beginning of August, having first asked and obtained permission to make a tour on the Continent. It was understood that the intention now was to marry the Princess Charlotte to the prince of Orange, eldest son of the king of the Netherlands; but on the 2nd May, 1816, she was married to Prince Leopold George Frederick of Saxe-Coburg, the present king of Belgium. Her melancholy death in childbed followed on the 6th of November, 1817, an event which placed the duke of York next in succession to the crown. On the 5th of January, in this last-mentioned year, when the Prince Regent went to open parliament, he was shot at on his return through the Park; two balls perforated the glass of the carriage. This occurrence and the excited state of the country led to the suspension of the Habeas Corpus Act, and to various other measures curtailing the public liberties. At this time, of seven sons of the king no one had any issue; in these circumstances, in order to provide for the continuance of the line of succession, the dukes of Clarence, of Kent, and of Cambridge were all married in the course of the year 1818. The duke of Cumberland had been married in 1815, but his son, the present crown-prince of Hanover, and now, after his father, the nearest heir to the throne, was not born till 1819.

The Prince Regent ascended the throne as George IV. on the death of his father, 29th January, 1820. The first great public event of the new reign was the detection, on the 23rd February, of the Cato-street plot to assassinate the ministers. Queen Caroline arrived in London on the 6th June, and on the evening of the same day a message from the king was delivered to both houses of parliament, communicating papers respecting her alleged misconduct while abroad. On the 5th July, a bill for divorcing and degrading her was introduced into the House of Lords by the premier, Lord Liverpool; the examination of witnesses in support and refutation of the charges on which this measure professed to be founded occupied some succeeding months. On the 6th November, the second reading of the bill was carried by a majority of 123 to 95; on the 10th the third reading was only carried by 108 to 99; on this division, which destroyed all chance of the measure passing the Commons, it was abandoned. The queen however did not long survive her escape. The coronation of the king took place 19th July, 1821, when her majesty, having previously claimed it as her legal right to be crowned at the same time as queen consort, was repulsed in an attempt to obtain admission at the doors both of Westminster Hall and the Abbey. A few days after she was taken ill, and

died at Brandenburgh House, Hammersmith, 7th August. The king was at this time absent on a visit to Ireland; in the end of September he set out for Hanover, from which he did not return till the beginning of November; and in August following he went to Scotland. The suicide of the marquis of Londonderry, secretary for foreign affairs, occurred while the king was absent on this last visit, and produced some change in the foreign policy of the administration. [CANNING, GEORGE.] The year 1822 was marked by severe agricultural distress and much discontent in England, and by more serious disturbances in Ireland.

Of the foreign transactions of the two or three following years, the most important were the recognition of the new states of South America, by sending consuls to them in October, 1823; the contest with the Ashantees, in 1824 [ASHANTEES]; and the commencement in April that year of the Burmese war, which terminated in February, 1826, in the treaty of Yandaboo, giving the British a considerable accession of territory on the eastern coast of the Bay of Bengal. Of domestic events during the same period, the most memorable is the great commercial crisis of December, 1825. In December, 1826, a body of troops was sent to Portugal to support the princess regent and the constitution established by Don Pedro against the hostile attempts of the Spanish government and of the absolutist faction organized by that power; the British force speedily put down the rebellion and restored tranquillity. The death of the duke of York, 22nd January, 1827, transferred the character of heir presumptive to the duke of Clarence; and the office of commander-in-chief, in which the duke of York had been replaced soon after the commencement of the regency, to the duke of Wellington. The termination of the political life of Lord Liverpool by a stroke of apoplexy followed on the 17th of February; the consequence of which was a complete change of ministry. In the beginning of April Mr. Canning was appointed first lord of the treasury, and soon after chancellor of the exchequer, on which the great body of the whigs became the supporters of the new administration, while it was opposed by the duke of Wellington, Lord Eldon, Mr. Peel, and others of the premier's former friends and colleagues. [CANNING, GEORGE.] The death of Mr. Canning however, on the 8th of August, made a new arrangement necessary. Viscount Goderich (now earl of Ripon) then became premier, the duke of Wellington being reappointed to the command of the forces, with a seat in the cabinet. Some time after this arrangement had been completed, the news arrived of the destruction of the Turkish fleet in the Bay of Navarino in Greece, by the attack of the combined squadrons of England, France, and Russia; an occurrence which in his Majesty's speech, delivered at the opening of parliament, 29th January, 1828, was characterized as 'a collision wholly unexpected,' and an 'untoward event.' Meanwhile differences, of which various explanations were afterwards given, but which may be suspected to have had some relation to the affairs of Greece and Turkey, as well as to other matters both of foreign and domestic policy, had led to the resignation of Lord Goderich, and the appointment, on the 25th of January, of the duke of Wellington as first lord of the treasury. The new ministry however was still composed in part of the friends of the late Mr. Canning, as well as of the members of the tory party. This state of things lasted till the end of May, when a sudden misunderstanding or difference of opinion produced the resignation of Mr. Huskisson, which was immediately followed by that of Lord Dudley, Lord Palmerston, and Mr. Charles Grant. The ministry now came once more to be composed wholly of persons generally considered as belonging to the extreme, which was at the same time the main, division of the tory party. In particular, every member of the cabinet had hitherto been resolutely and steadily opposed to the concession of what was called the emancipation of the Catholics, and indeed to every other proposed mitigation, whether in substance or even in form, of the rigid Protestantism of the state institutions. The most important among the other events of this year were, the return, 5th July, of Mr. O'Connell, although a Catholic, as representative to the House of Commons for the county of Clare; the convention concluded 6th August, between Ali Pacha, viceroy of Egypt, and Sir Edward Codrington, for the evacuation of the Morea by the Turkish troops, in conformity with which the whole Egyptian armament sailed for Alexandria on the 4th of October; the resignation by the duke of Clarence, 12th August, of the office of lord-high-admiral, to which he had been appointed by Mr. Canning; the recal, in December, of the marquis of Anglesea from the government of Ireland; and the visit to this country, in the latter part of the year, of Donna Maria da Gloria, the young queen of Portugal. On the 26th of February, this year, Lord John Russell had carried his resolution in the House of Commons for the repeal of the Test and Corporation Acts, against the opposition of ministers, by a majority of 237 to 193. A bill to effect the object of the resolution was afterwards introduced, and ministers refraining from joining the opposition to it in the House of Lords, it was passed into a law. This measure had till now been uniformly resisted by both sections of the administration under which it was thus conceded.

The great measure of domestic policy of the year 1829 was the concession at last of Catholic emancipation. The consideration of the laws imposing disabilities on Roman Catholics, with a view to the practicability of their safe removal, was recommended in the king's speech, delivered at the opening of parliament on the 5th of February. The Relief Bill, and another abolishing the forty-shilling freeholders in Ireland, were brought into the House of Commons together by Mr. Secretary Peel, and read a first time on the 10th of March. The second reading of the Relief Bill was carried on the 18th by a majority of 353 to 173; on the third reading, 30th March, the numbers were, ayes 320, noes 142; the second reading in the Lords was carried 4th April, by a majority of 217 to 112; and the third reading on the 10th, by a majority of 213 to 104. Both bills received the royal assent on the 13th. Mr. O'Connell presented himself to take his seat for Clare on the 15th of May following; but after he had been heard at the bar, it was resolved by a majority of 190 to 116, that he [illegible] oath of supremacy; and on his refusal to take the said oath, a new writ was ordered to be issued for Clare.

In the early part of the year 1830 the king, who had for some time past lived in great seclusion, was attacked by an illness which soon assumed a serious appearance. After all prospect of his recovery had been for some time lost, he died at Windsor Castle on the morning of the 26th of June, in the sixty-eighth year of his age, and the eleventh of his reign. The same day proclamation was made of the accession of his late majesty king William IV.

Many important alterations of the laws were made in the reign of George IV., besides the great national measures that have been already noticed. Both the laws relating to the punishment and those relating to the trial of offences were consolidated and amended by several acts introduced by Mr. Peel, in which, and also in the general administration of the law, considerable progress was made in the application of the two great principles of diminishing the sanguinary character and increasing the certainty of punishments. Among the other legislative innovations of the reign may be enumerated, the act of 1823, abolishing the antient custom of burying persons who had committed felo-de-se in cross-roads, with a stake driven through their bodies; the Marriage Act Amendment Acts of 1822, 1823, and 1824; the act of 1824, for the restoration in blood of the representatives of the Scottish peers attainted in 1715 and 1745; the act of the same year for ascertaining and establishing a uniformity of weights and measures; the act of the same year for the repeal of the combination laws; the act of 1827 to prevent arrests upon mesne process where the cause of action is under 20*l.*; the act of 1828 for rendering a written memorandum necessary to the validity of certain promises and engagements; the act of th[illegible]ame year for regulating the importation of corn; the Metropolis Police Act of 1829; the act of 1830 repealing the beer duties; and the act of the same year substituting the punishment of transportation, instead of that of death, for forgery. The mention of these measures is sufficient to indicate the progress of legislation during the reign.

GEORGE I., surnamed the Long-handed, grand-duke of Russia, was the son of Vladimir Monomachos, who married Gyda, daughter of Harold, the last Saxon king of England. After the death of her father at the battle of Hastings, in 1065, Gyda retired to Sweden, from which country she married Vladimir, about 1070. It is however impossible to ascertain whether George was the son of the English princess, as his father was married three times; but it is very probable, as George died in 1157, at an advanced age. He was of a very ambitious and grasping cha-

racter, a circumstance from which he derived his surname, the *Long-handed*. Having received for his appanage the principality of Soozdal, situated in the north of Russia, he tried to establish himself on the grand-ducal throne of Kieff, which was possessed by his nephew Isiaslaf, and he succeeded in driving him from that principality (1149), but he was soon afterwards expelled himself by the Hungarians, who restored Isiaslaf. After many vicissitudes he attained his object, and became grand-duke of Kieff in 1155. He died two years afterwards. The reign of George is remarkable for the foundation of Moscow in a spot where, as the chroniclers relate, there lived a rich man named Koochko, of whose wife George became enamoured, and where, after causing the husband to be murdered, and having established for some time his residence there, he laid the foundation of a future city. George was very partial to the southern principalities of Russia, and being for a long time unable to possess any of them, he built several towns in his own dominions, to which he gave the names of those cities which were situated in the south; as for instance, Vladimir, Peryaslav, &c. His own dominions, inhabited originally by several Finnish tribes, living in an almost savage state, and being mostly idolaters, became civilized under this reign by the foundation of cities, churches, and monasteries.

George peopled the new towns with settlers of Sclavonian and Finnish stock, whom he attracted by granting them privileges and several other advantages. This is the origin of the population of Grand Russia, generally known under the name of the Muscovite or Soozdalian, which being a mixture of Sclavonians and Fins, exhibits a striking contrast in physical appearance, language, manners, and character to all the other Sclavonian populations. This people ought never to be confounded with the real Russians, who inhabit the south-western provinces of the present Russian empire, as well as Galicia, or Austrian Poland, and who, being of a pure Sclavonic race, much more resemble in every respect the Poles, the Slovacks of Hungary, and other people of Sclavonian race, than the population of Grand Russia. After the reign of George I., the northern principalities acquired great importance, and his son Andrew increased his power and established his residence at the town of Vladimir, which was built by his father on the banks of the Klasma. Instead of aiming at the possession of Kieff, which conferred the empty title of the Grand-Duke of Russia, and which was captured and sacked by his son and a coalition of other princes (1159), he assumed that title in his own dominions. He strengthened his power by exiling all his brothers, who found refuge at the court of the Emperor Manuel Comnenus. Andrew was murdered by some conspirators in 1174. After two years of civil war, during which Michel, prince of Rezan, for a short time occupied the throne of Vladimir, Vsevolod, brother of Andrew and son of George I., obtained the grand-ducal dignity, which he preserved till his death in 1212. His long reign was tranquil, and the chroniclers, who call him the Great, extol his justice also. Brought up at the court of the Greek emperor, where he spent his boyish years, must have had an education superior to that of his countrymen. He embellished his capital with splendid edifices, and fortified it as well as several other towns.

GEORGE II., son of Vsevolod and grandson of George I., became grand-duke, not immediately after the death of his father, but after that of his competitor, the Grand-Duke Constantine, in 1219. His reign is marked by one of tl most important events of the middle ages, which has produced the most decisive influence on the condition of Russia; we mean the invasion of the Moguls, the circumstances of which cannot be well understood without previously giving a short sketch of the state of Russia at the beginning of the thirteenth century.

The dominions of Vladimir the Great (who died in 1015) extended almost from the Baltic to the Black Sea, and from the frontiers of Hungary and Poland to the banks of the Volga, containing several tribes of Sclavonians in the south and the west, and of Fins in the north and the east, who were forcibly united under the dominion of the Varingian or Norman dynasty of Ruric, but divided by that monarch between his twelve sons. From that time the different principalities, although occasionally united, continued to be subdivided by several successive sovereigns, so that at the period in question there was a great number of minor princes besides the two great principalities of Vladimir in the north and of Halich in the south. The most important neighbours of Russia at that time were the nomadic nation of the Polovtzee, called by the Byzantine writers Comans, who established themselves, about the middle of the 11th century, in the countries along the shores of the Black Sea from the banks of the Don to those of the Danube. By their inroads they became formidable to all their neighbours, but particularly to the Russian princes, by whom they were also often hired as auxiliary troops. In 1224 the Mogul expedition sent by Gengis Khan under his son Joodgee Khan, to extend his conquests in the west, attacked the Polovtzee, whose chieftains, being defeated by the Moguls, fled to Russia, and entreated the Russian princes to assist them against an enemy, who, as they expressed it, 'has taken our country to-day and will take yours to-morrow.'

The Russian princes of the south, influenced by Motislaf, duke of Halich, listened to the Polovtzee, and having assembled an army of about 100,000 men, which was joined by great numbers of the Polovtzee, marched against the Moguls.

It was a wise measure to oppose the savage hordes before they had invaded the country, and the Russian and Polovtzee forces were sufficient to repel them; but dissension among the princes and the cowardice of the Polovtzee weakened the army, which was entirely defeated by the Moguls on the 31st of May, 1224, on the banks of the river Kalka (now Kalmius) in the present government of Ekterinoslaf, near the town of Mariopol. The Moguls after this victory extended their devastations as far as the banks of the Dnieper, but although no resistance was offered, they suddenly retired from the Dnieper into the deserts of central Asia, and their invasion produced on the minds of the inhabitants the effects of a supernatural apparition.

George II. had despatched an auxiliary force against the Moguls, but on their way they heard of the fate of the Russian expedition, and returned without meeting the invaders.

The Russian princes soon forgot the invasion of the Moguls, and instead of thinking of the possibility of their return, abandoned themselves to their usual broils and internal as well as external feuds. Nothing was heard of the Moguls till 1237, when a report was spread that they had invaded the country of the Bulgarians, situated on the banks of the Volga, in the present government of Kasan. It was Batoo Khan, grandson of Gengis Khan, who was sent by his uncle Oktay with 300,000 men in order to extend his conquests to the west, and with instructions to give peace only to the conquered nations. The report was followed by the appearance of the invaders, who entered the principalities of Rezan, and summoned its sovereign to submit and to give up the tenth part of all his and his subjects' property. The Duke of Rezan, with some minor princes, resolving to oppose the Moguls, sent a message to the grand-duke George requesting his assistance; but George relying on his own forces refused to join them, and decided on awaiting the approach of the enemy in his own dominions. The Moguls took and destroyed Rezan after a brave defence, and massacred the inhabitants. Moscow, Kolomna, and many other cities shared the same fate. George entrusted the defence of his capital Vladimir to his sons, and retired to a fortified camp on the banks of the river Sit. The capital was taken by storm in February, 1238, and every thing was destroyed with fire and sword.

George II., whose two sons perished at Vladimir, awaited the enemies in his position, and though attacked by an overwhelming force fought bravely till he was killed, on the 4th of March, 1238. The Moguls soon retired beyond the Volga, but in the next year they invaded Southern Russia, and having devastated a part of Hungary and Poland, penetrated as far as Liegnitz in Silesia, where they were repulsed in a battle with the Silesian dukes assisted by the Germans.

Batoo Khan returned to the banks of the Volga, where he summoned the Russian princes to pay him homag Resistance was hopeless, and the grand-duke Yaroslaf, brother to George II., was the first who acknowledged the sovereignty of the Grand Khan. This is the beginning of the Mogul or Tartar domination in Russia, which lasted till about 1470.

GEORGE, ST., surnamed of *Cappadocia*, was a native of Epiphaneia in Cilicia, and is said to have been born in a fuller's shop. From this obscure and servile origin he raised himself by the talents of a parasite, and the patrons whom he assiduously flattered procured for their worthless

dependant a lucrative commission or contract to supply the army with bacon. He accumulated wealth in this employment by the basest arts of fraud, and his depredations on the public purse at last became so notorious, that he fled from the pursuit of justice, taking his ill-gotten wealth with him. The place of his retreat was Alexandria, where he embraced, with real or affected zeal, the profession of Arianism. Here he formed a valuable library of history, rhetoric, philosophy, and theology, which the Emperor Julian, after St. George's death, appropriated to himself. So great had the influence of George of Cappadocia become amongst the disciples and followers of Arius, that when Athanasius was driven from Alexandria the prevailing faction elevated him to the vacant episcopal throne. Gibbon has enlarged upon the avarice and tyranny of his character whilst primate of Egypt. The Alexandrians, says Gibbon, could never forget nor forgive the tax which he suggested on all the houses of the city, under an obsolete claim that the royal founder had conveyed to his successors, the Ptolemies and the Cæsars, the perpetual property of the soil. The Pagans, who had been flattered with the hopes of freedom and toleration, excited his devout avarice; and the rich temples of Alexandria were either pillaged or insulted by the haughty prelate, who exclaimed in a loud and threatening tone, 'How long will these sepulchres be permitted to stand?' Under the reign of Constantius he was expelled by the fury, or rather the justice, of the people; and it was not without a violent struggle that the civil and military powers of the state could restore his authority and gratify his revenge. The messenger who proclaimed at Alexandria the accession of Julian, A.D. 361, announced the downfal of the archbishop. George, with two of his obsequious ministers, Count Diodorus, and Dracontius, master of the mint, were ignominiously dragged in chains to the public prison. At the end of twenty-four days the prison was forced open by the rage of a superstitious multitude, impatient of the tedious forms of judicial proceedings. The enemies of gods and men, observes Gibbon, expired under their cruel insults; the lifeless bodies of the archbishop and his associates were carried in triumph through the streets on the back of a camel. The remains of these guilty wretches were thrown into the sea; and the popular leaders of the tumult declared their resolution to disappoint the devotion of the Christians, and to intercept the future honours of these *martyrs*, who had been punished, like their predecessors, by the enemies of their religion. The fears of the Pagans were just, and their precautions ineffectual. The meritorious death of the archbishop obliterated the memory of his life. The rival of Athanasius was dear and sacred to the Arians, and the seeming conversion of those sectaries introduced his worship into the bosom of the Catholic church.

The reader who would enter into the history of St. George of Cappadocia as the patron saint of England may consult 'The Historie of that most famous Saint and Souldier of Christ Jesus, St. George of Cappadocia, asserted from the fictions of the middle ages of the Church and opposition of the present,' by Dr. Peter Heylyn, 4to. Lond. 1631 and 1633; 'A Dissertation on the Original of the Equestrian Figure of the George and of the Garter, ensigns of the most noble Order of that name,' by John Pettingall, 4to. Lond. 1753; and Dr. Pegge's 'Observations on the History of St. George, the Patron Saint of England,' in the 'Archæologia,' vol. v., p. 1-32.

When the English Crusaders went to the East in 1096, they found St. George received among the Christians as a warrior-saint, with the peculiar appellation of *Tropæophoros* (Τροπαιοφόρος) *the victorious*. They had some knowledge of him before as a saint and martyr, having read of him in that capacity in their Calendars and Martyrologies; and, after the succour which he was supposed to have afforded them at the siege of Antioch, they adopted him as the patron of soldiers. As such, Edward III. made him patron of the Order of the Garter; and he thus gradually became considered as the patron of chivalry, and the tutelar saint of England.

GEORGETOWN. [COLUMBIA, DISTRICT OF.]

GEORGIA. This article comprehends not only a description of Georgia Proper, but of all the countries between the Black and the Caspian Seas of which Russia either holds or claims possession, and which form dependencies of the government of Georgia, or, as the Russians call it, Grusia. This tract extends from 38° 31′ to 43° 30′ N. lat., and from about 41° to 52° 12′ E. long. It is enclosed on the north by the range of the Caucasus, which forms a part of the country; on the east it is washed by the Caspian, and on the west by the Black Sea; on the south it is bounded by Persia and Asiatic Turkey, having a line of frontier on that side of about 600 English miles. Its utmost breadth, from the Cape of Abcheron or Apsheron on the Caspian Sea, to the mouth of the river Chorokee, which falls into the Black Sea, is about 480 English miles; and its greatest length, from the banks of the Araxes to those of the Kooma, is about 500 English miles.

The countries on the eastern shores of the Black Sea were known to the early Greeks, as we infer from the history of the expedition of the Argonauts: and several Greek colonies, such as Dioscurias and others, were established here at an early epoch. The Romans became acquainted with the Caucasian regions during their wars with Mithridates and with the kings of Armenia. In the fifth, sixth, and seventh centuries of our æra those regions became the theatre of frequent wars between the emperors of the East and the Sassanide kings of Persia. In the eighth and ninth centuries they were partly conquered by the generals of the khaliphs of Bagdad, whose dominion however was not of long duration. From the eleventh to the end of the twelfth century the kings of Georgia acquired great power, and exercised a paramount influence over all the Caucasian isthmus. But their power was overthrown by the invasion of the Moguls of Gengis Khan, who overran these countries about the beginning of the thirteenth century, and rendered them tributary. Towards the end of the fourteenth century they were again invaded by Tamerlane, when they suffered even more than under Gengis Khan. After the death of Tamerlane the kings of Georgia expelled the Mohammedans and resumed their power; but the unfortunate division of the country which Alexander I., king of Georgia, made among his three sons in 1424, plunged it again into a miserable condition. About the beginning of the sixteenth century the sovereigns of Kakhet, or Eastern Georgia, became vassals to the sophis of Persia, and from that time were reckoned among the valees, or lieutenants, of the Shah. Towards the end of the same century the sovereigns of Kartli and of Imiretia, as well as all the western part of the Caucasian isthmus, fell under the domination, or at least the influence, of the Ottoman Porte; and the country between the Black and the Caspian seas became from that time a constant field of battle between the Turks and the Persians.

From the sixteenth century the czars of Moscow endeavoured to establish their influence in the Caucasian regions. Their projects were favoured by their community of religion with the Georgians, who repeatedly requested their assistance against the oppression of their Mohammedan neighbours. But the unsuccessful expedition which the Moscovites undertook in the beginning of the seventeenth century against the highlanders of the Eastern Caucasus stopped their projects of conquest in that quarter till the time of Peter the Great. This monarch in person made an expedition in 1724 against the highlanders of Daghestan, and took Derbend. This expedition was followed by a treaty with Tamas Shah of Persia, who, being driven from his states by the Afghauns, ceded to Russia, on the promise of being restored to his throne, the provinces of Daghestan, Shirvan, Ghilan, Mazanderan, and Asterabad. Although the promised assistance was never given, the provinces were taken possession of by Russia, and held till the year 1735, when they were restored by the empress Anne to the celebrated Nadir Shah.

The fortunes of Georgia were restored for a moment after the death of Nadir Shah, by Heraclius II., a Georgian prince, educated in the camps of that conqueror, whom he had accompanied on his expedition to India. After a long reign spent in constant wars with his neighbours, Heraclius adopted a measure which he thought would ensure the safety of his country, but which proved destructive to his dynasty. He declared himself in 1783 a vassal of Russia, which guaranteed to him and his successors not only the possession of his actual dominions, but even of those which he might thereafter conquer. Persia was at that time disturbed by internal wars and could not resent the desertion of her

vassal, but in 1795 Agha Mohammed Khan led an army into Georgia and defeated Heraclius, who, being abandoned by the Russians, tried to oppose the invaders with an inferior force. Tiflis was taken by the Persians, who destroyed the town and led a great number of its inhabitants into captivity. Heraclius died in 1798, and was succeeded by his son George XIII., a weak-minded prince, whose reign was constantly disturbed by a civil war with his brothers. George died in 1800. After his death Georgia was declared a Russian province, and the members of the reigning family were carried to Russia. A few years afterwards several provinces situated on the shores of the Caspian Sea were taken by the Russians, and their possession of them was confirmed by the treaty of Goolistan, concluded in 1813, between Russia and Persia. The sovereign of Imiretia, who had become a vassal of Russia in the beginning of the present century, made in 1810 an unsuccessful attempt to shake off his yoke; but he was obliged to flee to Turkey, and his principality was converted into a province of Russia. Several other petty states fell successively under the same power, whose conquests were extended during her last wars with Persia and Turkey, and confirmed by the treaty of Turkmanchay in 1828, with the first, and that of Adrianople in 1829, with the second of the above-mentioned powers.

The mountain-ranges of the CAUCASUS and of ARARAT are described under those respective heads.

The principal rivers which drain the Caucasian isthmus are the Koor, or antient Cyrus, the Araxes, the Rion or Faz (the antient Phasis), the Kooban, and the Terek, besides numerous smaller rivers and streams. Owing to the hilly nature of the country only two of these rivers are navigable, and that only for flat-bottomed vessels—the Koor, from its confluence with the Araxes to its outlet into the Caspian Sea, for about 70 English miles, and the Rion, for about the same distance.

The country, though generally mountainous, contains some extensive plains. The southern latitude of these regions and the high mountains by which they are surrounded and intersected produce that variety of climate which adapts them to the production of various plants and animals proper both to warm and cold climates. Of wild animals there are the panther, the jackal, the tiger, the bear, the wolf, &c. Besides the domestic animals common to the northern countries, there is a great number of camels and asses. A great variety of birds is found in these regions, of which the most remarkable is the pheasant, which is indigenous on the banks of the Rion, or Phasis, from which river it has derived its name. The slopes of the mountains are covered with large forests, which produce timber of the best description.

The vine, which is indigenous, grows abundantly in a wild state. The vineyards produce a great variety of grapes, and a large quantity of wine and brandy is made in the country. Silk is cultivated in several provinces, but this branch of industry is still in a very low state, owing to the unskilful preparation of that valuable commodity. The present annual exportation amounts to 15,500 poods. (A pood is about 36 lbs.) Cotton is grown in the southern provinces, but it is of very inferior quality, and the whole quantity exported is only 36,000 poods. It is however said that by an improved management the cotton might be brought to the greatest perfection, and its quantity increased to an unlimited amount. Madder grows spontaneously in several parts of the country, but is cultivated chiefly in the provinces bordering on the Caspian. The inhabitants of the district of Derbend are almost exclusively occupied with the cultivation of it. In 1832 they produced 35,000 poods of madder roots, valued at 47,000*l*. Rice grows almost everywhere except in the highlands; and saffron is produced in great quantities in the eastern provinces.

There is every reason to believe that great mineral wealth is concealed in the mountains, but hitherto nothing of any importance has been discovered. The present commerce of these countries by the Caspian Sea is carried on from the ports of Derbend, Baku, Shamakhi, and Lenkoran, to Persia and to Astrakan. The overland trade is with Russia and Persia, as well as with Asiatic Turkey. The commerce by the Black Sea is carried on from the mouth of the Rion with Odessa and other Russian ports, as well as with Constantinople; and there is a small traffic with the highlanders of the Caucasus.

The system of taxation is of the most oppressive and absurd character; and is rendered particularly vexatious by the numerous monopolies which exist in several places, and by the duties which are levied on goods passing from one province to another. These duties were established by the petty princes who formerly possessed the dominion of this country; but although the separate states are now united, the former customs and duties still remain.

The amount of the population is exceedingly doubtfu Of the several conflicting estimates the only one on which any reliance can be placed is the official returns of the population of some of the provinces entirely subject to Russia, and which we shall give under the special description of each.

The government of these countries is concentrated in the person of the governor-general, who resides at Tiflis, and who is at the same time commander of a considerable military force called the Caucasian corps. The governor-general determines all the civil and military affairs of these provinces, and directs the minor diplomatic relations with the neighbouring countries.

The ecclesiastical affairs of the Armenian church are directed by their patriarch, who resides at Echmiadzin; and those of the Georgian church by the Catholicos, or metropolitan of Georgia. The religious concerns of the Mohammedans are directed by a mooshtend, who is acknowledged by the Russian government as the religious chief of the Mohammedan inhabitants of the country.

The country is politically divided into the following provinces:—Georgia Proper, the Armenian provinces, the provinces of Daghestan, Akhalzik, Imiretia, the provinces of Shirvan, Sheki, Talish, and Karabagh. Besides these provinces, which are incorporated in the Russian empire, the following states acknowledge her sovereignty or claim her protection, although they are governed by native princes:—Mingrelia, Gooria or Gouriel, and some petty states in the Daghestan. Many highland tribes are only nominal vassals of Russia, and, instead of submitting to her commands, are constantly at war with her.

Georgia Proper consists of the former kingdoms of Kakhet and Kartli, which were united under the domination of Heraclius II., in the eighteenth century. It contains, according to official returns, together with the districts of Borchalin, Kasakh, Shamshadil, Bambaco-Shooraghel, and Elizabethpol, joined to it by the Russian government, and inhabited by Mohammedans and Armenians, a population of 225,395 males, inhabiting 61,201 houses, on a surface of 46,400 square versts.* The principal town is Tiflis, the antient metropolis of Georgia, and at present the seat of government for all the Caucasian provinces of Russia. It is situated in 41° 40′ N. lat., and 45° 16′ E. long., and extends along both banks of the river Koor for about 1½ English miles. In its external appearance it presents a striking diversity, produced by the mixture of Oriental and European civilization. The town is surrounded on the south and west by a ridge of barren rocks; and on the north, the Caucasus, with its snow-covered tops, is within sight. This contrast with the fertile valley in which Tiflis is situated amidst orchards and vineyards gives to the town a very picturesque and pleasing appearance. The population amounts to 26,000 souls, composed chiefly of Armenians, a much smaller number of Georgians, a few Mohammedans and German colonists settled in its immediate vicinity, besides the Russian troops, civil officers, and merchants. The inhabitants of Tiflis, Armenians as well as Georgians, bear a very bad character, and are said to have all the vices which are produced by long oppression, united with a greediness after gain. Such however is not the character of the Georgians of the country; and indeed a nation which has preserved its religion notwithstanding ages of persecution, and which has seized every opportunity of regaining its independence, has a just claim to some respect. The Georgians who inhabit the country have the reputation of being exceedingly attached to their religion and country, honest, simple-hearted, laborious, and brave. These honourable qualities are tinged with an admixture of vanity, irascibility, and some other defects common to less civilized nations.

The language of Georgia bears a great resemblance to the Armenian. The Armenian historians say that previous to the time of Alexander the Great, Georgia formed a part of Armenia, but was separated from it during the commotion produced in Asia by the wars of that conqueror and his successors; and that since that time the language of

* 1½ Russian versts are equal to 1 English mile.

Georgia has received an admixture of many foreign words. Besides the Armenian, which constitutes its basis, the Georgian is full of Greek, Latin, Persian, Arabic, Turkish, and other foreign words. The idiom of the Pshavi and other Georgian highlanders, who have had less intercourse with foreigners, is more free from this admixture, and much nearer to the language of the Georgian sacred books, which were chiefly written in the fifth century of our æra.

Georgia was converted to Christianity by Armenian missionaries, who introduced into the churches of this country the worship in the Armenian tongue, which however was not understood by the people. In 410 a learned Armenian named Mesrop invented an alphabet for the Georgians, and soon afterwards the Bible and other religious books were translated into the Georgian language. A new kind of letters, used for ordinary writings, were invented about the 10th century, which are distinguished from the old characters by a greater simplicity; the difference between the two alphabets may be compared to that which exists between the Gothic and the present Latin letters. The new alphabet is called by the Georgians Mkhedroolee, or the Military one, and the old one Khootzoora, or the Ecclesiastical. Although fourteen centuries have passed since the Georgian language had an alphabet, it is not yet subject to definite rules. It has a dictionary, although a very incorrect one, and there are also some treaties on grammar and rhetoric, imitated from the Persian and Armenian, and in modern times from the Russian. But there is no real Georgian grammar, except some elementary works, written by foreigners, in order to facilitate the learning of the language. Such are the Georgio-Italian dictionary, published at Rome in 1629, by Stephen Paulini and Nicephorus Irbacchi. A Georgian grammar was also published there by Mogius in 1760. In 1820 there appeared at St. Petersburg a Russo-Georgian grammar. A printing-office was established at Tiflis by King Archil in the middle of the 17th century, and some religious books were printed there. Under Vakhtany the Sixth, who published a code of laws, many works were also printed, and their number was still increased under the reign of Heraclius the Second. The printing establishment was destroyed at the sacking of Tiflis by the Persians in 1795. The Russian government has now established a printing-office with Georgian, Persian, and Russian letters.

The population of Georgia is divided into the following classes:—1st. The Tavadis (literally heads), who constitute the higher nobility. 2nd. The Asnauris, or nobles. 3rd. The Mokalaks, or citizens (from Kalakh, a town) 4th. The Glekhs, or peasants. The Russian government in taking possession of Georgia gave to the Tavadis the title of princes, and to the Asnauris that of nobles. Both these classes have in Russia the same privileges as the nobles of that country, and have the same right to possess serfs.

Before the Russian dominion was established, the Tavadis were divided into three classes, distinguished by the sum of money paid for the murder of an individual belonging to their body. Thus the sum paid for the assassination of a Tavadi of the first class was double of what was paid for one of the second: and the penalty for the murder of a Tavadi of the second class was double of that for one of the third class. The Asnauris were likewise divided into three classes, which stood in the same relation to each other as those of the Tavadis. There were instances of some Asnauris being subject to the Tavadis, to whom they were given into hereditary bondage by the sovereign.

The Mokalaks, or citizens, live in the towns, and chiefly at Tiflis. They are generally engaged in trade, and their whole body pays to the government a fixed sum which they assess upon themselves. The peasants are serfs in Georgia, and belong either to the crown, the church, or to the princes and nobles.

The other towns of Georgia are, Signakh, the chief place of the district of that name, with about 3000 inhabitants; Telav, a well-built town in the Oriental style, with more than 3000 inhabitants; Doochet, a fortified place, with about 1300 inhabitants; Goree, a commercial town, with about 3500 inhabitants; and Elizabethpol, or Ganjah, formerly the capital of a Khanat, and the residence of a vassal prince. Elizabethpol is a large town, which contains even now, in its dilapidated state, 2000 houses, with above 6000 individuals, and several fine mosques and other public buildings. The town is fortified, and has been frequently exposed to the calamities of a siege and capture. All the towns enumerated are capitals of districts, which are called after them.

The administration of Georgia consists of three departments, executive, financial, and judicial, the heads of which, with the addition of some inferior magistrates, form, under the presidency of the governor-general, the supreme council of Georgia. Civil cases are decided according to the code of Vakhtany, the sixth king of Georgia. When its provisions prove insufficient recourse is had to the Russian law, by which all criminal cases are decided.

There is at Tiflis a school supported by the government, one by the Armenians, and an ecclesiastical seminary for the education of the Georgian clergy.

Imiretia.—It has been already mentioned that Alexander I., king of Georgia, in 1424 divided his dominions among his three sons; he gave Imiretia to one of them. The various fortunes of this little country, which fell under the dependence of Turkey in 1576, present too little interest to require mention.

Imiretia is situated between 41° 45′ and 42° 40′ N. lat., and between 42° 9′ and 43° 39′ E. long. On the north it borders on the main ridge of the Caucasus, and is separated on the east by a branch of it from Georgia Proper; on the south it borders on Akhalzik; and on the west on Mingrelia. Its area is calculated to be about 9200 square versts. Being sheltered from the northern winds by the Caucasus, its climate is mild, and in many parts the trees blossom and produce fruit twice a year. The large forests with which the country is overgrown prevent the free circulation of air, and engender a kind of malaria. The soil is exceedingly fertile, and the climate favourable to the cultivation of all the products of warm countries. Its population, which amounts to 100,000, consists chiefly of Imiretians and a few Armenians. The Imiretians speak a dialect of the Georgian language, and are politically divided into the same classes as the Georgians. Their manners and customs are also the same. The lower classes are very laborious, and remarkable for their physical strength. Many of them go to Tiflis to gain a livelihood by their labour. The government is vested in a Russian general, who commands the military force stationed in Imiretia, Mingrelia, Gooria, and Abkhazia, and who is dependent on the governor-general of Georgia. He presides over the civil department, which is composed of three Russian and two native magistrates, called Divan Begs. This department decides on all civil cases, and superintends the administration of the finances. Criminal cases are decided by a military commission. Civil affairs are decided according to the code of Vakhtany, and whenever it is defective recourse is had to the Russian law. Criminal cases are judged exclusively according to the Russian law. Every district is governed by a Russian intendant, assisted by two native officers.

Imiretia is divided into four districts: Kootais, Vakee, Shoropan, and Rachee.

Kootais, on the Rion, the metropolis, and the only town of Imiretia, was formerly the residence of its kings, and is now the seat of the Russian government. It is the capital of the district of the same name, as well as of the whole country. The place is divided into the old and new town, the former of which is of great antiquity, and contains a church built in a splendid style of Byzantine architecture. The new town is constructed in the European manner, and its streets are planted with nut, fig, and other trees. The number of inhabitants, exclusive of the Russian garrison, is only 2000. In the neighbourhood of Kootais is the monastery of Ghelat, which is surrounded by mountains containing sulphur springs, naphtha wells, and also a kind of black amber.

Akhalzik.—By the treaty of Adrianople Turkey ceded to Russia a part of the pashalik of Akhalzik which now forms the Russian province of that name. On the north it borders on Gooria, Imiretia, and Mingrelia; on the east, on Georgia; on the south, on the pashalik of Kars; on the south-west, on the part of Akhalzik which has remained under the Turkish domination. It is situated between 41° and 42° N. lat., and between 42° 39′ and 44° 1′ E. long. Its area is more than 7000 square versts.

The country is generally hilly, but very fertile, and the climate is healthy. The mountains contain numerous mineral springs, many of which have medicinal properties. The population, which amounts to 7000 souls, consists of Armenians, Georgians, Greeks, Koords, Turks, Jews, and Gipsies. The country is divided into ten sandjacs, or districts, some of which are governed by Russian officers,

and others by natives called sandjac-begs, who, instead of a salary, receive the revenue of certain estates, as was the case under the Turkish dominon. They all however depend upon the Russian governor residing at the town of Akhalzik.

The principal towns are: Akhalzik, the capital of the province, a fortress supposed to have been built by the celebrated queen Thamar. It contains 13,500 inhabitants. Akalkalaki, also a fortress, has 1000, and Khertvis 600 inhabitants.

The *Armenian provinces* are composed of the khanats of Erivan and Nakhichevan, ceded to Russia by Persia in 1828. [ERIVAN.] They contain a surface of about 11,000 square versts, a great part of which is hilly, besides the mountain of Ararat. There are however many plains with a very fertile soil. The products of Erivan are the same as those of Georgia, but with the addition of a kind of cochineal, called by the natives red worms, and which, according to Mr. Hamel (a learned naturalist), are a kind of insect which has never yet been described. They are much larger than the American, and are found on the roots of a plant called by Baron Marshal Biberstein ('Flora Tauro-Caucasica') *Poa pungens*, and by the Academician Trinius *Æluropus lævis*. Mr. Hamel maintains that this is as fit for dyeing purposes as the American cochineal. Though its use is now exceedingly limited, it may become a very important article of commerce. The population, according to the official returns of 1834, consisted of 22,336 families, containing 65,300 males, of whom 29,690 were Mohammedans, and the rest Armenians.

Besides the town of Erivan, the most remarkable places of the province are, the important fortress of Sardar Abad, and the convent of Echmiadzin, the residence of the Armenian patriarch.

The province of Nakhichevan, which forms the south-eastern part of Russian Armenia, is divided into two districts: Nakhichevan, and Ordoobad. The former contains about 3000 square versts, inhabited by 6538 families, of whom 2678 are Armenians, and the rest Mohammedans. According to the official returns of 1832, the number of males was 16,095. The climate of the hilly part of this district is healthy, but in the plains it is exceedingly hot and unwholesome. It contains some valuable salt mines. The town of Nakhichevan, situated in 38° 59′ N. lat., was in antient times one of the most important cities of the Armenian empire, and the Persian historians relate that it then contained 40,000 houses. It has been many times captured and sacked, yet when it was visited by Sir John Chardin, in the seventeenth century, it contained 2000 houses, besides numerous caravanserays, baths, and other public buildings. Extensive ruins attest the former grandeur of that city, which has now a population of only 1330 families, comprehending 2870 male individuals, although the circumference of the town is about four English miles. Not far from Nakhichevan is the fortress of Abbasabad, constructed on the left bank of the Araxes by some French engineers in the Persian service.

The district of Ordoobad contains about 1200 square versts, inhabited by a population of 3160 males, of whom 2157 are Mohammedans, and the rest Armenians. The district of Ordoobad being very fertile and enjoying a particularly healthy climate, has been named 'the earthly paradise.' The chief place of the district is Ordoobad, which contains about 600 houses.

The Mussulman Provinces.—A large tract of land extending along the shores of the Caspian Sea, and containing the present provinces of Baku, Derbend, Shirvan, Kooba, Sheki, with the peninsula of Apsheron and the island of Salyan, once formed a part of Albania, which belonged to the powerful monarchy of Armenia till the sixth century, when being conquered by the Sassanide monarch of Persia, Khosroo Nooshirvan, it assumed the name of Shirvan. For some time afterwards it had its independent sovereigns, who took the title of Shah, but were obliged, towards the end of the ninth century, to acknowledge the supremacy of the khaliphs.

The rulers of Shirvan long continued powerful, and had frequent wars with Persia. In the beginning of the fifteenth century, Emir Ibrahim of Shirvan conquered Azerbijan, took Tauris, and even Ispahan, the capital of Persia. But the terrible revolutions which agitated that country, towards the end of the fifteenth century, brought it under the dominion of Persia, and Shirvan never recovered its independence. Divided among several rulers nominated by the Shah, it remained under the dominion of Persia until it was gradually invaded and finally subjugated by Russia.

Shirvan borders on the province of Kooba on the north; on the east, on that of Baku and the Caspian Sea; on the south, on a bay of the same sea, and the provinces of Talish and Karabagh; and on the west, on the province of Sheki. The surface of the whole province, including the island of Salyan, is estimated at 14,500 square versts. It contains many plains, and, except in the mountainous part, is exceedingly fertile. The climate in the plains along the shores of the Caspian is very hot and unhealthy, but this high temperature, with the great fertility of the soil, renders it capable of producing many tropical plants.

The bulk of the population of Shirvan consists of the Tahtar, or, to speak more correctly, Turkish race, with some admixture of Arabs and Persians. It may be divided into several classes; as the begs and agas, or nobles, the clergy, the maafs, the maaf-nookers, and the peasants. All these distinctions originated under the former native governments, and are rather connived at than maintained by Russia. The begs are the landowners, to whom the peasants living on their lands are obliged to make certain payments in money, and others also in kind or in labour. The dignity of the beg was granted by the sovereign, and continued in the family more by custom than by law. The title of aga is given to those individuals who are descended from the families of the khans. The clergy enjoy great consideration among the natives, being the expounders of the Koran, by which not only the religious but the civil concerns of the Mohammedans are regulated. The maafs are individuals exempted from every tax and duty, generally only for a certain period. This immunity was acquired either by some services rendered to the khans or by purchase. The maaf-nookers were exempted from the payment of every kind of taxes, but were under an obligation to serve the khan in the field, and to perform certain services, such as the carrying of despatches, collecting imposts, &c. The peasants are all free, and there are no serfs among the Mohammedans of the Caucasian provinces. The merchants, artisans, and other inhabitants of towns pay no direct taxes to the government, but are obliged to provide military quarters, horses, or cattle for military transport, and to contribute to the maintenance of public buildings, &c. Besides the Mohammedans, who form the mass of the population, there are many Armenians, some Jews, and a few Gipsies. According to the official returns of 1831, the number of males belonging to the Mohammedan population was 62,934; Armenians, 6,375; Jews, 332: total males, 69,641.

The prevalent language of Shirvan is what is there called Toorkee or Turkish, which is also used in Azerbijan.

The principal products of Shirvan are rice, silk, wine, some cotton, and tobacco. The climate, particularly of that part which is called the Island of Salyan, and which is in fact the Delta of the Koor, is so warm and so fertile that it would produce in the greatest abundance many tropical plants, but its natural advantages have hitherto been turned to little account. This island has also rich fisheries, which bring in to the government, on an average, an annual revenue of about 28,000*l*. The industry of Shirvan consists chiefly in the manufacture of silken stuffs, which are concentrated in the town of Old Shamakhee and some villages in its vicinity, and which occupy about 700 looms, each requiring the co-operation of four individuals. There are also some cotton manufactures as well as a few tanneries in the same place. The district of Laguish, which is situated in the mountains and in a very cold and barren region, is inhabited by a population entirely distinct from that of the rest of Shirvan, who are exclusively employed in the fabrication of arms, copper vessels, and sundry metal wares, from which they derive considerable profit, as is apparent from their condition being superior to that of the rest of the inhabitants of Shirvan. The commerce which is carried on with Persia by the Caspian Sea, and with Astrakan and Tiflis overland, is not considerable.

The chief place of the province is the town of Old Shamahkee, which was celebrated for its trade during the middle ages, when it was the chief mart and the centre of that commercial intercourse which we have already described. It continued to be an important city, notwithstanding the change of the above-mentioned commercial route, as well as many political vicissitudes; and it was in

the most flourishing condition at the beginning of the eighteenth century, when it was sacked (1717) in the most barbarous manner by the highlanders of Daghestan. Since that time Shamahkee has never recovered its antient splendour, and it is now inhabited, according to the official returns of 1832, by only 2233 families.

The khanat of *Talish*, being situated between 38° 31′ and 39° 31′ N. lat., is the most southern possession of Russia. On the north it borders on the steppe of Moghan, which makes part of Shirvan; on the east, on the Caspian Sea; and on the south and west it is enclosed by the Persian dominions. This province is entirely mountainous, with the exception of one great plain, which runs between the mountains and the sea, and contains about 3000 square versts. Its soil, with few exceptions, is a black loam capable of producing the most luxuriant vegetation. This richness of the soil, combined with a hot climate and abundance of water, renders it practicable to cultivate various tropical products on the plain of Talish; and many persons who have examined the country consider that the sugar-cane, cotton of the finest quality, indigo, and the orange-tree, &c., would succeed perfectly; while the slopes of the mountains are very favourable to the cultivation of the vine, as well as the almond, olive, and other trees which require a dry soil. At present the state of agriculture is very low, and the greatest part of the grounds are only used as pastures.

The climate, which is now rather unhealthy on account of the great number of marshy grounds, may be improved by draining these swamps, which contain an extraordinary quantity of snakes and other venomous reptiles. It is a great advantage to the khanat of Talish that it is situated along the sea-coast, which offers great facilities to its commerce. It has two ports, or rather roadsteads: Lenkoran, which is so shallow that vessels can never approach the coast nearer than one mile, and are frequently obliged to anchor even at a greater distance; and Sara, which is the best port in the Caspian Sea. Sara is situated on the north-western side of a little island of the same name, and is about 2½ English miles from the shore. Vessels drawing 14 feet water can come within 150 fathoms of the coast. It is the usual station of the Russian war flotilla.

The population of the khanat of Talish is of the same description as that of the province of Shirvan, and all that we have said respecting it is applicable to the inhabitants of Talish. The amount of the population seems not to have been exactly ascertained. There are some few wandering tribes, who live in a very wild state, and are much addicted to predatory habits. The industry of Talish is in a very low state, and limited to the production of some silk, rice, honey, &c. The manufactures supply a few silk and cotton stuffs. The chief and only town of the province is Lenkoran, in 38° 43′ N. lat. and 48° 54′ E. long. It is a wretched place, with about 500 houses.

The province of *Karabagh*, which is separated on the south by the Araxes from the Persian dominions, and enclosed on all other sides by the Russian provinces of Shirvan, Sheki, Elizabethpol, Nakhichevan, and Erivan, has an area of about 13,000 square versts. From its extensive forests, it has received the name of Karabagh, which signifies, in the Turko-Tahtar language, 'a black garden.' Many parts are covered with hills; the highest, called Saree Dara, is 5000 feet above the level of the Caspian. These hills are generally covered with wood or fine grass, and barren rocks are very rare. There is a great plain which contains about 2400 square versts, and a soil almost universally fertile; even the greatest part of the hills are covered with a black loam. The climate in the high parts is rather cold. The plains are hot and unhealthy. Besides the Koor and the Araxes, the province is drained by a great number of small rivers and mountain streams, which afford great facilities for irrigation. The products of Karabagh, owing to the hilly character of the country, are those of a moderate rather than a warm climate, and the forest-trees are of the same description as those of Europe, and supply timber of the best quality. The mineral products consist of a small quantity of naphtha, copper, and salt, collected from lakes.

The population of Karabagh, according to the official returns of 1832, consisted of 13,965 Mohammedan and 1491 Armenian families, besides some Nestorian Christians and Gipsies. This limited population may be ascribed to the frequent wars which have long desolated the province, and to the emigration to Persia of many Mohammedan families since its subjection to Russia, although many Armenians were induced by the Russian government, after the peace of Toorkmanchay, to emigrate from Persia to Karabagh.

All that has been said of the Mohammedan population of Shirvan and Talish is equally applicable to that of Karabagh, with the exception that, besides the two Mohammedan sects of the Shiites and Soonnees, there is a third, called Aliallaga. Its followers are distinguished, besides a particular veneration for Ali, by abstinence from tobacco and snuff, which is carried so far, that they shun the intercourse of those who make use of them; but they drink wine and distilled liquors.

The Armenians of Karabagh have a nobility, consisting of some families to whom Shah Abbas the Great granted the title of melihks or princes, which is enjoyed by their descendants. They have a numerous clergy, comprising two archbishops, many bishops, abbots, and several convents, besides the secular clergy. Both clergy and laity are very ignorant, and their religious observances are much relaxed. Anybody who is married to a virgin, and is able to read, may become a priest by remaining in a church, or a room attached to it, during forty days and nights, and reading the Scriptures. Having passed this probation, he is consecrated by the local bishop; but should the priest, after having lost his first wife, marry again, he loses his sacred character. The Armenians of Karabagh have intermingled with their religion many Mohammedan and even Pagan rites and customs. They are called to the church by a public crier, and enter it without uncovering their heads. At the baptism they give Mohammedan names to their children, and sacrifice several kinds of animals and birds to the saints at the entrance of churches. The Nestorians have emigrated into Karabagh from Persia since the treaty of Toorkmanchay.

The only town in Karabagh is Shooshee, situated on a high rocky mountain, about 4000 feet above the level of the Caspian. It is fortified by nature and a little by art: it contains about 1700 houses. The population is composed of 762 Armenian and 936 Mohammedan families. The Missionary Society of Basel has an establishment at Shooshee, composed of a few missionaries, who maintain gratuitously a school for the natives, where, besides the Christian religion, are taught the Armenian language, arithmetic, and geography, as well as the Greek and English languages. The missionaries have also a small printing-office, in which they print some religious tracts and school-books in Armenian. There are also two Armenian schools, one for boys, and another for girls; and 7 Mohammedan schools, besides one established by the Russian government.

The province of *Sheki* is situated between 40° 10′ and 41° 16′ N. lat., and 45° 56′ and 48° 7′ E. long. On the north it borders on a part of the Caucasian ridge called Salvat-dagh and Shak-dagh, by which it is separated from several independent tribes of the Lesghis; on the east on the province of Shirvan; on the south on that of Karabagh; and on the west on the territory of the sultan of Elisooy and the district of Elizabethpol. Its length from north to south is something more than 70 English miles, and its breadth in the northern part about the same; but it narrows towards the south. The surface is calculated at about 9000 square versts. The country is generally mountainous, but there are also some level tracts; the climate is temperate, except during the few summer months, when the heat becomes oppressive in the plains. The products consist of different kinds of grain, which are cultivated in the hilly part. Silk is produced in the plains: this latter branch of industry has of late made great progress, and may become very important by the improvements introduced into the preparation of the silk by an establishment for preparing it after the European manner, which was made by the government in 1829. Some cotton is also cultivated in the plains; but although circumstances are favourable to its growth, it is now produced to a very small amount, and of a rather inferior kind. Some silks of a good quality are manufactured by the women in several villages. Great flocks of sheep and cattle are reared in the province.

The population of Sheki amounts, according to the official returns of 1833, in the town of Nookha, and 270 villages, or nomadic encampments, to 21,264 families, consisting of 55,773 males. This number comprehends 46,300 Mohammedans, 8938 Armenians, and 485 Jews. What has been said about the Mohammedan and Armenian

populations of the other provinces is applicable to those of Sheki. The Jews are engaged in a petty retail trade.

Nookha, the chief place of the province, contains about 6000 inhabitants. It is in a valley, inclosed on all sides by mountains, a circumstance which prevent a free circulation of air, and accounts for the unhealthiness of the place. Sheki, which is now a small village, must have been a considerable place, since it has given its name to the whole province. Fit-dagh, a little fortress situated on a mountain of the same name, has naturally a very strong position, and in former times served as a place of refuge to the khan, when he was defeated by his enemies.

Baku is on the shores of the Caspian Sea, between 48° 9′ and 50° 12′ E. long. A great part of this province is formed by the peninsula of Apsheron, which juts into the Caspian Sea. Its surface is calculated at about 2800 square versts; the soil is generally poor, and the climate, although hot, is not unhealthy. Among the natural productions of the province, the most remarkable is naphtha or petroleum, which is found in great quantity close to the shores of the Caspian. It is drawn from wells dug in the ground. There are two kinds of naphtha, the white and the black: it is exported to Persia, and partly consumed in the Caucasian provinces, where it is used for lighting the houses. There are many salt lakes on the peninsula of Apsheron, which furnish a great quantity of salt. The population, according to the official returns, amounts to 15,128 male individuals. They are generally Mohammedans, of the Shiite sect; all that has been said about the manners and customs of the inhabitants of other Mohammedan provinces is equally applicable to them. They are however more industrious than the other Mohammedans, and are in a comparatively better condition. The active commerce which is carried on by Baku on the Caspian Sea greatly favours their industry. [BAKU.]

The province of Kooba borders on that of Baku on the south. It contains a surface of about 10,500 square versts. The western part of the province is hilly; but there are extensive plains of the most fertile soil along the shores of the Caspian. The climate is rather cold in the mountains, but warm in the plains. The country produces in abundance every kind of corn, with some rice, cotton, silk, and tobacco. Numerous flocks graze on the rich pastures. The population, according to the official returns of 1832, amounts to 46,094 males, who are Mohammedans. Kooba, the capital, and the only town of the province, contains about 650 wretched houses, built in an irregular manner.

Derbend has already been described. [DERBEND.]

All the above-mentioned provinces are governed by Russian military commanders.

Having described the Russian provinces which constitute the government of Georgia, we shall give a brief sketch of those countries which, having preserved their national rulers, acknowledge the supremacy of Russia, and are dependent on the governor-general of Georgia.

Mingrelia.—This principality, which extends along the banks of the Rion, or Phasis, was well known in antiquity under the name of Colchis. It became subject to the Romans; and after the capture of Constantinople by the Latins formed a province, or at least a dependency of the empire of Trebizond. The Turks took possession of it in the latter part of the fifteenth century, but left the government to the native princes, who continued vassals of the Porte till the treaty of Kaynargee in 1774, between Russia and Turkey, by which Mingrelia was declared independent. In 1804, George Dadian, prince of Mingrelia, acknowledged himself a vassal of Russia; and his son and successor Levan Dadian (Dadian is their family name), a Russian lieutenant-general, is the present ruler of that country.

Mingrelia lies between 42° and 43° N. lat., and 41° 19′ and 42° 19′ E. long. On the north it borders on the Caucasian range, on the west on Abkhazia and the Black Sea, on the east on Imiretia, and on the south on Gooria. Its greatest breadth is 60, and its length about 75 English miles. Its surface is calculated at about 10,000 square versts. The soil, climate, and productions are the same as those of Imiretia. The population amounts to 90,000 souls, and consists of Mingrelians and Souanets, with a few Abkhazians, Armenians, and Jews. The Mingrelians speak a dialect of the Georgian language, and profess the Greek religion. They have an archbishop and three bishops, subject to the spiritual supremacy of the Catholicos of Georgia. Their political divisions, and their manners and customs, are the same as those of Imiretia. The country is divided into three districts, called Sennakh, Legchoom, and Zoogdeet, and the territory of the Souanets, who are a highland tribe professing partly the Mohammedan religion, but their manners and customs are very little known. The little town of Sennakh is the chief place of the country, and the residence of the sovereign. Russia possesses on the coast the fortresses of Redout-Kale and Anaklia.

The principality of *Gooria* has long been governed by its own sovereigns, who are descendants of the Georgian dynasty, and have been vassals to the Ottoman Porte since the 16th century. In 1810 its ruler became vassal of Russia. He left on his death a son, a minor, to whom the succession to the throne was confirmed by the Russian government, under the regency of his mother, the Princess Sophia, with a Council of the first nobles of the country. The Princess Sophia, not being satisfied with the Russian protection, opened negotiations with the Turks in order to get rid of it. Her intentions were discovered, and she was obliged to flee with her son to the Turkish dominions. Since that time the government of the country has been intrusted to the abovementioned council of nobles, with a Russian field-officer at its head, and dependent on the Russian commander in Imiretia.

Gooria lies between 41° 40′ and 42° 5′ N. lat.; it is bounded on the north by Mingrelia, on the west by the Black Sea, on the east by Imiretia, and on the south by the Turkish possessions.

It contains about 1800 square versts. The country is very hilly, and covered with large forests, containing excellent timber for ship-building. The soil is exceedingly fertile; the products are the same as those of Imiretia and Mingrelia. The population, which consists of Georgians, and some Armenians, amounts to 36,700 souls. The population is divided into classes of princes, nobles, &c., as in Georgia.

The religion is Greek, and the church establishment consists of an archbishop and two bishops, under the spiritual superintendence of the Catholicos of Georgia. The country is divided into two districts, Ozoorget and Nagomar, each containing a little town of the same name. The most important place is the Russian fortress of Poti, at the mouth of the river Rion. It was taken by the Russians in 1[illegible] but was restored to the Turks at the peace of Bucharest in 1812. It was again captured by the Russians during the last war, and ceded to them by the treaty of Adrianople in 1829.

A general sketch of Daghestan has already been given. [DAGHESTAN.]

We shall here add a few particulars about the petty states which acknowledge the supremacy of Russia, and are considered as part of that empire.

The possessions of the Shamkhal of Tarkoo, which contain about 40,000 souls, extend along the Caspian Sea. The Shamkhal, although a vassal of Russia, governs his possessions with unlimited power. His dignity dates from the time when the Arabs conquered the country; and the name is Arabic, signifying 'the Syrian prince' (from *Sham*, Syria, and *khal*, prince). The Shamkhals had been for some time vassals of Persia, and had the title of Valee of Daghestan. They have several times acknowledged the supremacy of Russia, but it is only since 1786 that they have become permanently her vassals. Tarkoo, the capital of the Shamkhal's dominions, situated near the Caspian, contains a population of 8000 souls. Near it is the fortress Boornaya, which is garrisoned by Russian troops. The supremacy of the Shamkhal is nominally acknowledged by the Lesghian tribe of Acoosha, which is a kind of republic composed of about 10,000 families, who are much addicted to predatory habits, and are ready to enter the service of any body who will pay them. They never attack the Shamkhal, on whose pastures they are permitted to graze their flocks. Having revolted, they were defeated by the Russians in 1819, and since that time have remained tranquil.

The other vassal princes of Russia in those parts are the Ootsmey, or prince, of the Karakaydans, who rules over a population of about 69,000 souls; and the Cadee of Tabasseran, having a population of about 50,000 souls.

Lesghistan, or the country of the Lesghis.—The Lesghis inhabit a country situated between Daghestan, Georgia, the Caucasus, and the provinces lately acquired from Persia. The whole surface of their country is calculated

to amount to 20,000 square versts. Klaproth is of opinion that the tribe of Avars, which is the most important among the Lesghis, are descended from the antient Avars, who were a branch of the Huns. There is a great admixture amongst the Lesghis of Arabian blood, from the colonies which were settled there in the ninth century by the caliphs of Bagdad. Like all the Caucasian tribes, the Lesghis are of a savage character, and given to robbery. They are exceedingly brave, and capable of enduring the greatest hardships. They are most accomplished horsemen, but fight equally well on foot. They are always ready to sell their services to the highest bidder. The general price paid to an armed horseman is about 2*l.* for one expedition, which never lasts longer than four months. Besides this pay, the horseman receives victuals and forage. The Lesghi, who at home never obeys any body, strictly conforms during the war to the orders of the chieftain under whom he has engaged to serve. Before the occupation of the Caucasian Isthmus by the Russians, the friendship of the Lesghis was sought by all the petty princes who were at war with their neighbours, and those who had secured the alliance of these warlike highlanders were sure of success. By their depredations the Lesghis became the terror of the adjacent countries, and Georgia was particularly exposed to their inroads. It is generally towards the end of the month of May that the Lesghis leave their mountains and enter Georgia; they usually disperse in small parties, and conceal themselves in woods, caverns, or old ruins, watching a favourable opportunity to make captives. Having carried their prisoner to a place of safety, they send to inform the relations that they may redeem him on paying a sum equal to about 35*s.* Should the prisoner be a man of consequence, the ransom is much higher. The life of every prisoner depends on the will of his captor, but as soon as he enters his house he must no longer be killed. The prisoner who has not the means of paying his ransom is obliged to serve his master for ten years.

The majority of the Lesghian tribes profess the Mohammedan religion of the sect of Soonnee: there are however many who seem to have no religion whatever, while some f them have preserved a few faint vestiges of Christianity. Hospitality and the law of retaliation are the only social bonds among this people.

The khan of the Avars is the most powerful prince among the Lesghis. He rules over 270 villages, inhabited by a population of about 100,000 souls. In case of need he can raise an army of 10,000 men. The kings of Georgia used to pay him an annual tribute of about 1000*l.* He long maintained his independence against the Russians, and it was only in 1828 that he acknowledged himself their vassal. The other Lesghian tribes who acknowledge the supremacy of Russia are the Kazockoomooks, whose population amounts to 20,000 souls, the Djaro-Belakans, and the principality of the sultan of Elisooy. Several Lesghian tribes, who have a republican form of government, have preserved their independence. The most remarkable of them is the little community of Koobichee, which consists of about 1000 families, who inhabit a large village and a few small ones situated in a strong position. They are known all over the East by the name of Zerkers, or manufacturers of mail shirts. Some authors think that they are descendants of a European colony, but it has been proved by recent researches that their language is a dialect of that of the Lesghis, whom they resemble in many respects. They make arms of a very superior description, which, as well as their cloth, have a great reputation, not only in the adjacent countries, but also in Persia, and even beyond the Caspian Sea. It is indeed very remarkable to find in the midst of the savage tribes that inhabit these highlands an industrious and laborious population.

The Koobichees do not engage either in agriculture or the rearing of cattle, but they exchange the objects necessary to them for the products of their industry. Their friendship is sought by all the Lesghian tribes, whom they furnish with arms; but the Koobichees are always on their guard, and strictly watch the only two passes by which their country is accessible, and which they have fortified with small cannons. They are never at war with their neighbours; they pay neither taxes nor tribute, and are governed by a council of twelve elders, chosen by themselves.

The Highland tribes of the Mitsdjegi, or Kistes, are divided into four branches—1, the Kistes Proper; 2, the Ingooshes; 3, the Karaboolaks; 4, the Chechenzes.

1. The Kistes Proper are now a very small tribe, composed of about 1500 souls. They are subject to the Russian dominion, and maintained in their allegiance by the military line which crosses their country.

2. The Ingooshes are the most peaceful tribe of this nation, and more inclined to agriculture and sedentary occupations. Their population is about 4,500 families, now entirely subject to the Russian government.

3. The Karaboolaks were formerly one of the most formidable tribes of the Caucasus, and had long oppressed all their neighbours, till at last they were almost exterminated by a league of the surrounding tribes, excited by the wrongs which they had suffered from them. Their feeble remains acknowledge the Russian dominion, although they never lose an opportunity of committing depredations on their masters whenever they can do it with impunity.

4. The Chechenzes are the most indomitable and predatory tribe of the Caucasus, and all the efforts of Russia to subdue them have hitherto been unsuccessful. The severe chastisement inflicted upon them by the Russian general Yermoloff, compelled them to remain quiet for some time, but in 1830 they again rose against the Russians and committed great ravages. In 1832 a new Russian expedition was undertaken against them, and many of their villages were burnt, and the inhabitants massacred. This severe measure spread terror among the Chechenzes, but could not prevent their occasional robberies, and the road which leads from Russia to Georgia through their country is so insecure that no travellers venture to pass it without a strong military escort. The amount of their population is very uncertain.

The *Ossetes*, who inhabit a large tract of the Caucasus, and constitute a population of about 33,000 families, are entirely distinct in language and physical constitution from the other Caucasian tribes. Klaproth thinks that they are descendants of a Median colony, settled there at a very remote epoch. A great part of this nation, occupying the southern slope of the Caucasus, was reduced to subjection by the monarchs of Georgia. They profess the Christian religion of the Greek church; and although they have preserved their own language they resemble in many respects the inhabitants of Georgia, of which their country now forms a district.

The Ossetes who inhabit the northern slope of the Caucasus have preserved their independence, although they are nominally subject to Russia. They were early converted to the Christian religion, which however they have abandoned; and, except some obscure traditions and superstitious observances, and a great veneration for the ruins of antient churches, they have scarcely any religion whatever.

The Russian government having been informed that the country of the Ossetes contained gold and silver mines, ordered (1752) a convent to be built in their country, and monks were established in order to convert the natives to the Christian religion. At the same time they sent a commission to explore the mountains, and to ascertain the existence of the mines.

The apostolical labours of the missionaries were limited to the baptism of several natives, each of whom received on that occasion twelve yards of common linen, some victuals, and a metallic cross. This reward was a sufficient inducement to many of the highlanders to be baptized, but their knowledge of the Christian religion consisted in making the sign of the cross, and in calling themselves Christians. When the expectation of gold and silver mines failed to be realized, the Russian government did not support with any great zeal the new missionary establishment, which was destroyed in 1769 by the natives, in consequence of a quarrel between a missionary priest and one of the native chiefs.

The Ossetes are a very laborious and sober nation. They are chiefly occupied in hunting and in rearing flocks, the produce of which they exchange for different objects of necessity. Besides these occupations they engage in predatory expeditions whenever a fair opportunity presents itself of doing so with impunity.

The *Abases*, or Abkhases, occupy Abasia Proper, which extends from Mingrelia along the shores of the Black Sea, a distance of nearly 70 English miles, and contains a population of about 50,000 souls, under the nomina. dominion of a prince who acknowledges the supremacy of Russia. The Abasian population is not however con-

fined to that little district. It is intermingled with the Circassians all over the country that extends along the coast of the Black Sea as far as the banks of the Kooban. Klaproth estimates their population, which is divided into ten tribes, at about 54,000 families. The ruins of many churches, which are still held in great veneration by the natives, prove that the Christian religion was once established in this country: the exercise of it however seems to have been dropped among the Abasians many centuries ago; and about seventy years back they were converted, through the instrumentality of the Turkish government, to the Mohammedan creed. Their Islamism is however very imperfect, and limited to some rites and observances prescribed by the Koran. Their country is fertile, and has many large forests, which contain excellent timber. The climate is considered healthy. The nation is divided into four classes—1st, the princes; 2nd, the nobles; 3rd, the liberated serfs; 4th, the serfs. They resemble in many respects the Circassians, and are frequently confounded with them.

The great and little Kabardahs are inhabited by Circassians who have submitted to Russians. Their population is composed of about 15,000 families.

General observations on the Caucasian Highlanders.—The general characteristics of the Caucasian highlanders, although there are differences among them in origin, language, and many other respects, are a strong love of independence united with predatory habits. Robbery is considered the most honourable occupation of a free-born man, and the greatest reproach that a Circassian girl can make to a young man is, 'You have not been able to steal even a cow.' Their education and their early habits are calculated to inure them to the hardships of a life spent in constant danger. A Circassian prince never educates his son at home, for fear of his being spoiled by the tender care of a mother. The son of a prince is entrusted to the care of some noble three days after his birth, and the father never sees him before his marriage. The boy remains all this time with his tutor, who teaches him the warlike exercises in which the Circassians excel. He undertakes with him the first warlike expeditions, and chooses for him a wife, after which the young prince returns to his family. Hospitality is a sacred duty among all these highlanders. Whenever a Caucasian has received a person into his house, he will protect him against all his enemies, even at the risk of his life. The law of retaliation is more strictly enforced among the Caucasians than among the Beduin Arabs: to avenge the death of a relation becomes a sacred obligation which descends from father to son, unless the quarrel is settled by a compensation accepted by the aggrieved party.

Although many Caucasian tribes have been converted to Mohammedanism, the most part of them may be called idolaters, as they frequently worship some inanimate objects. It is very remarkable that the prophet Elijah is a particular object of adoration among almost all the Caucasian tribes, both Mohammedan and Pagan. There are several caverns in different parts of the Caucasus consecrated to this prophet, where the inhabitants assemble on certain days to offer sacrifices to him. If a person is killed by thunder, the highlanders say that he was killed by the prophet Elijah, and consider it a great blessing for him. The burial of such a person is accompanied with the songs and dances of his relations, who rejoice in his death instead of mourning at the event. The attempts made by the Russian government to civilize the Caucasian highlanders have generally proved abortive. There are many instances of individuals belonging to those tribes, who being educated in Russia have risen to a high rank in her military service, but nevertheless have returned to their own country and abandoned European manners and customs for those of their ancestors.

GEORGIA, the most southern of the United States of North America, on the shores of the Atlantic Ocean. It extends from north to south between 30° 32′ and 35° N. lat., and from east to west between 81° and 85° 40′ W. long. Its length is 300 miles, its greatest breadth 280, and its mean breadth 203 miles. Its area is 61,000 square miles, or about 3000 square miles more than the surface of England and Wales together.

It is bounded on the east by the Atlantic. On the south it is bounded by Florida for 255 miles, the river St. Mary, constituting the boundary-line for about 80 miles; on the west lies Alabama, with a boundary-line of 306 miles. On the north lie the States of Tenessee, and of North and South Carolina. Its common boundary with the first is 80, with the second 67, and with the last 260 miles. The Savannah River separates Georgia from South Carolina, and the Chattahoochee, a branch of the Appalachicola, divides it for a considerable extent from Alabama.

The line of coast, extending 105 miles in a straight line, runs from south-south-west to north-north-east, with a slight bend westward. Though generally uniform as to course from point to point, it is very irregularly indented, and skirted by numerous islands, which are low, and in their length extend parallel to the shores. The principal of these islands from north to south are Tybee, Warsaw, Ossabow, St. Catherine's, Sapello, St. Simons, Jekyl, and Cumberland. These islands, as well as some tracts on the adjacent shore, have a light sandy soil, well adapted for the culture of cotton. The cotton grown here, known by the name of Sea-Island cotton, fetches a higher price in the market than any other. The inlets and sounds which divide the islands from one another, and penetrate several miles inland, are generally very shallow, and admit only vessels of less than 100 tons. Vessels of larger dimensions can enter only three harbours. The bar at the mouth of St. Mary's, at the most southern extremity of the State, has thirteen feet of water on it; that at the mouth of the Alatamaha, between St. Simons and Sapello, fourteen feet, and the embouchure of the Savannah seventeen feet of water; the last-mentioned river is navigable for larger vessels to the city of Savannah.

The surface of Georgia is naturally divided into two regions, a plain and a hilly country. The boundary-line between them is indicated by the falls of the rivers which occur in the Savannah, near Augusta, in the Oconee, near Milledgeville, in the Ocmulgee, near Macon, in the Flint River, at Fort Lawrence, near Knoxville, and in the Chattahoochee, near Fort Mitchell. The plain which occupies the country south of this line extends in its western prolongation through the states of Alabama and Mississippi to the banks of the river Mississippi, and continues north-eastward through the states of South and North Carolina and Virginia to Chesapeake Bay. In Georgia it is a dead flat along the shores of the ocean, with a sandy soil, which produces no trees but the pine and palmetto. In many places it is intersected with swamps, which are however less numerous and less extensive here than in the more northern states, but still occupy perhaps one-tenth of the whole tract. The largest of these swamps is the Okefinoke Swamp, near the boundary of and partly within Florida, which is about 50 miles in length and 30 in breadth. In the rainy season, when the greater part of it is covered with water, it appears like an inland sea.

This swampy tract ceases about 50 or 60 miles from the sea, except the Okefinoke Swamp, which lies farther inland. West of the swampy tract the country is dry, and the soil consists of a mixture of sand and loam; but being commonly destitute of water, it is nearly unfit for cultivation. Only along the bottoms of the rivers there occur level tracts from a quarter to half a mile wide, which, in their natural state, are covered with reeds, and have an excellent soil, well adapted to the growth of most agricultural productions, particularly rice. The higher dry grounds are mostly covered with pines.

The hilly region, which occupies nearly the northern half of the state, contains a much greater portion of arable land. The best land is along the rivers, where the soil is a deep, rich, black mould, with a small portion of sand. The gentle declivities of the hills also contain large tracts of cultivable land, and it is only their dry and sandy summits which do not admit of cultivation and are covered with pines. The productiveness of the country which till lately belonged to the Cherokees is very imperfectly known. The most southern ridges of the Appalachian mountains occur along the northern boundary-line of Georgia, but they do not appear to attain a great elevation, probably nowhere more than 1500 feet above the level of the sea.

The rivers which drain Georgia fall partly into the Gulf of Mexico and partly into the Atlantic. The former traverse either Alabama or Florida before they reach the sea. The most western is the Etowah river, a branch of the Coosa, one of the principal branches of the Alabama. The Etowah drains the country lately in possession of the Cherokees, and runs about 80 miles within Georgia. The

most important river of Georgia which falls into the Gulf of Mexico is the Appalachicola, or rather its two principal branches, the Chattahoochee and Flint rivers; for it is only at the extreme south-western angle of this state that these two rivers unite and take the name of Appalachicola. The Chattahoochee rises between the most southern spurs of the Appalachian range, about 34° 40′ N. lat. It runs in a general south-western direction through the northern part of Georgia for about 200 miles, and in approaching 33° N. lat. it begins to turn gradually to the south until it flows due south, forming for about 190 miles the boundary between Georgia on one side and Alabama and Florida on the other. It runs above 400 miles before it joins the Flint river. The Flint river rises in the western districts of the hilly region, between 33° and 34° N. lat., and flows in a southern direction as far as 32° N. lat., whence it gradually declines towards the west, until, south of 31° N. lat., it turns nearly due west, and joins the Chattahoochee. Its whole course is about 210 miles. The Ocklockonnee and Suvanee, two rivers of Florida, rise in the southern districts of Georgia, and the Ogeechee in the northern.

The most southern river that falls into the Atlantic is St. Mary's river, whose sources lie partly in Okefinoke Swamp, and partly north of it. It flows with a very tortuous channel, first south, then east, afterwards north, and again east, and enters the sea between Amelia and Cumberland islands, after a course of 110 miles. The Alatamaha runs through the central districts of Georgia; it is formed by the rivers Ocmulgee and Oconee, both of which rise towards the centre of the hilly region, near 34° N. lat., and run to the east of south for 160 miles nearly parallel to one another, at a mean distance of 40 miles. Having passed the parallel of 34°, the Ocmulgee turns east, and joins the Oconee near 30° N. lat. The river thus formed, called Alatamaha, flows first east and afterwards bends to the south-east, until it empties itself in the ocean between St. Simons and Sapello islands. Its course is about 90 miles, and the whole length of the river upwards of 280 miles. Larger vessels can only ascend this river to Darien, but boats of 30 tons are navigated up the Oconee to Milledgeville, and an equal distance up the Ocmulgee. The Savannah river rises on the most southern declivity of the Appalachian range, and runs in all its course of 250 miles south-south-east, forming in all this distance the boundary between Georgia and South Carolina. It is navigable for large vessels to the city of Savannah, and for vessels of 70 tons to Augusta.

The climate of a country extending over more than four degrees of latitude, and whose northern half is several hundred feet more elevated than its southern districts, must of course present great varieties. The hilly region is rather cold in winter. Frost is of common occurrence, and snow sometimes falls to the depth of five or six inches. But these districts are very healthy. The plain approaches in its climate the tropical regions of the globe. It is unhealthy on the bottoms of the rivers, and along the sea-coast in the vicinity of stagnant water. The heat in summer is very great, and the thermometer sometimes rises to 98° or even 102°. Its common range is between 76° and 90° in this season; but as the trade-winds on the coast of the New Continent advance in summer to 32° or 33° N. lat., they moderate the heat. Yet this season is very inconstant, and subject to storms of thunder and lightning. In winter the thermometer ranges between 60° and 40°, and sinks occasionally lower. The weather however is then dry and constant, and this is considered the most healthy and pleasant season of the year. The rains are most frequent in spring.

The great difference in the climate produces a corresponding difference in the productions. In the southern districts the temperature is suitable to the sugar-cane, orange, olive, fig, pomegranate, &c. Agriculture however is mostly limited to Indian corn, sweet potatoes, cotton, rice, tobacco, and indigo. The hilly region resembles, in climate as well as in products, the countries of Middle Europe. The greatest part of the plain is covered with several kinds of the pine, a tree which extends also over the higher portion of the hilly region. But along the sea-coast as well as on the bottoms of the rivers, oak, hickory, ash, palmetto, and some other trees, are common.

Bears and deer are very numerous in the forests and near the swamps. Alligators frequent the Alatamaha and other rivers. Honey-bees are frequent in the swamps east of Flint river. The rivers abound with several kinds of fish.

Iron and copper occur in several places in the hilly country, and the ore is said to be rich. The gold region of the Southern States passes through the country of the Cherokees. From the hills dividing the plain from the northern districts millstones are obtained, and sometimes exported to the northern States of the Union.

The whole population of Georgia is now composed of Europeans and Africans, or their descendents. Not a trace remains of the old Indian population. The Creeks, who up to 1826 inhabited the country between the Flint and Chattahoochee rivers, sold their lands in that year, and emigrated to the banks of the Arkansas. Up to 1835 the Cherokees were in possession of the north-western corner of the state, but in that year were obliged to abandon it. [CHEROKEES.] The population consisted at the last census (in 1830) of 516,520 individuals, of whom 217,470 were slaves, and little more than 2000 free blacks. This population is very unequally distributed over the surface of the country. The counties along the upper course of the Savannah, and those along the hills which divide the plain from the hilly region, are the best peopled: the greatest part of the plain, and also the north-western corner of the state, are nearly uninhabited, though the last, the country of the Cherokees, is fertile and well adapted to agriculture.

The agricultural produce of Upper Georgia is not exported, being of the same description as that of the northern states, which have the advantage of the vicinity of the sea, good harbours, and an easy internal navigation, whilst Upper Georgia is about 150 miles from its ports, which besides have not water enough for large vessels. The expense of bringing the wheat and flour to these ports is so great as to preclude the farmers from entering into competition with the northern states. Only a comparatively small quantity of tobacco and live-stock are brought down the country. The agricultural produce of Lower Georgia consists principally of cotton, rice, sugar, and indigo, all of which form articles of export. The imports into this state consist principally of manufactured goods, East India products, and wines from the southern countries of Europe. An active commerce is carried on with the northern states, which furnish butter, cheese, fish, and some other articles of less importance. Slaves are also imported from Virginia and other northern slave-holding states.

The difficulties attending the internal commerce of the state have prevented the growth of large cities. Savannah, situated about 17 miles from the mouth of the river of the same name, has a population of about 7500 souls, and carries on a very active trade in the staple articles of the country, a large part of which is shipped for Charleston. The capital of the state is Milledgeville, on the river Oconee, where it begins to be navigable for steam-boats; it has about 3500 inhabitants, and in its neighbourhood vines are cultivated with success. At Athens [ATHENS], an insignificant place north of Milledgeville, is Franklin College, an extensive institution erected in 1785, which however, up to this time, has not answered the intentions of the government. Augusta, on the Savannah river, a town of about 7000 inhabitants, carries on an active inland trade: it has also a medical college. Darien, not far from the mouth of the Alatamaha, has also some commerce, and a population of 2000. St. Mary, near the mouth of St. Mary's river, contains only 800 inhabitants.

The colony of Georgia was founded in 1732 by a private company, and received its name in honour of King George II. In 1733 General Oglethorpe founded the town of Savannah. In 1752 it became a royal government, and in 1755 a provincial legislature was established. It joined the other provinces in 1776 in declaring war against Great Britain; but in 1778 was occupied by a British force, and continued in such occupation till the peace of 1783. A new constitution was introduced in 1785, and afterwards amended in 1798. The legislative body is composed of a senate and a house of representatives. The senators, ninety in number, and the one hundred and eighty-five members of the house of representatives, are elected annually. Every free white male citizen twenty years of age and paying taxes has a vote in the election of the members of both houses. The governor, who is invested with the executive power, is chosen by the legislative body for the term of two years. The state sends two members to the senate and nine to the house of repre-

sentatives at Washington. (Darby's *View of the United States*, &c.)

GEORGICS. [VIRGIL.]

GEORGI'NA, a name sometimes given to the Dahlia, but improperly.

GEORGIUM SIDUS. [URANUS.]

GEO'RYCHUS, Illiger's name for the *Lemmings* of Cuvier. [MURIDÆ.]

GEOSAURUS, Cuvier's name for a subgenus of Saurians, found in a fossil state only, and considered by him as intermediate between the *Crocodiles* and the *Monitors*.

The author of a review in the 'Zoological Journal' (vol. iv. p. 255) on the 'Nova Acta physico-medica Academiæ Cæsareæ Leopoldino-Carolinæ Naturæ Curiosorum,' tom. xiii. (Bonn. 1826–7), with reference to an article therein, by Dr. Ritgen, in which the doctor proposes the restoration of the pelves of three species of animals from the fossil fragments of their skeletons, has this passage: 'The first of them is the *Lacerta gigantea* of Soemmering, *Mosasaurus* of Conybeare and Parkinson, for which Dr. Ritgen, without assigning a single reason for the change of name, is pleased to adopt the more than sesquipedalian title of *Halilimnosaurus crocodiloides*. This appellation however may serve, in some degree, to explain his views of its affinities and original habitation, inasmuch as it shows that he regards it as a lacertine animal resembling a crocodile and inhabiting salt-water marshes, intermediate therefore between the extinct *Enaliosauri*, or sea-lizards, and the living crocodiles of fresh-water streams. It is, moreover, the *Geosaurus* of Cuvier's "Ossemens Fossiles." There is some little obscurity here, which we will endeavour to dispel. That Cuvier's name, *Geosaurus*, should be retained according to the laws of nomenclature, there can be no doubt; and it appears that this provisional name was given, not in reference to the habits of the extinct lizard, but, to use Cuvier's own words, ("par allusion à Terre, mère des Géans")—by an allusion to Terra, the Earth—Ge (Γῆ) of the Greeks, the fabled mother of the Giants. Indeed the sclerotic plates still remaining in the portion of the cranium figured by Cuvier in his "Ossemens Fossiles," could not have escaped the observation of that acute zoologist (who was so eminently alive to the laws of co-existence), as indicating aquatic habits. That he considered it subgenerically different from *Mosasaurus* appears from the following observations: Immediately after the allusion to the origin of the name, Cuvier says, "I cannot retain for it the epithet *giganteus* (Je ne peux lui laisser l'épithète gantesque); for, in the great genus *Lacerta* we have already the animal of Maestricht, or *Mosasaurus*, which greatly surpassed it, and there is also another (the *Megalosaurus*) which is very superior in size—(nous avons d'abord l'animal de Maestricht, ou *Mosasaurus*, que le surpasse de beaucoup, et nous allons en voir un autre (le *Mégalosaurus*), qui lui est aussi très supérieur)."'

Again, in a note to the previous article in the 'Ossemens Fossiles,' on *Mosasaurus*:—'With regard to the fossil animal of Monheim ('*Geosaurus*'), which M. de Soemmering has also regarded as identical with that of Maestricht (*Mosasaurus*), we shall see in a succeeding article that it differs from the Maestricht animal in many respects.' M. Hermann von Meyer, in his most useful work, 'Palæologica zur Geschichte der Erde und ihrer Geschöpfe,' (8vo. Frankfort, 1832), widely separates the two subgenera. The first, *Geosaurus*, he exemplifies by *Geosaurus Sömmerringii*, syn. *Lacerta gigantea*, Sömmering, *Halilimnosaurus crocodiloides* of Ritgen. The second, *Mosasaurus*, Conybeare, *Saurochampsa*, Wagler, he exemplifies by *Mosasaurus Camperi*, syn. *M. Hofmanni*, *Lacerta gigantea*, Sömmering, zum Theil (in part). In his 'System der Fossilen Saurier,' which fossil Saurians he divides into four sections, denoted by the letters A, B, C, and D, he places *Geosaurus* under section A—(Saurier mit zehen, ähnlich denen an den lebenden Sauriern*), and *Mosasaurus* under section C—(Saurier mit flossartigen Gliedmassen†).

The remains upon which Cuvier founded his subgenus were found in the canton Meulenhardt, at the depth of ten feet, and a few paces from the crocodile described by Cuvier (Gavial of Monheim and of Boll; 'Oss. Foss.' tom. v. pp. 120–125: *Crocodilus priscus* of Sömmering; *Æolodon priscus* of Hermann von Meyer), by the labourers employed to work the mines of granular iron (fer en grains) which fills the fissures of the strata of calcareous schist.

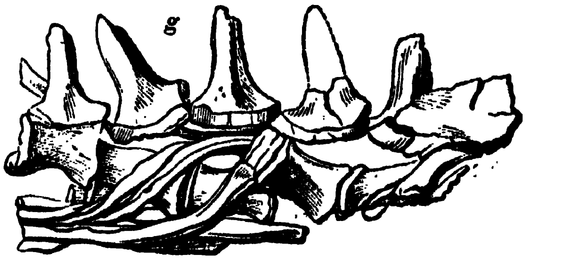
c d e

f

* Saurians with toes similar to those of existing Saurians, and either four-toed or five-toed. Geosaurus is placed in the four-toed group, with an indication of doubt, in consequence of the want of sufficient materials.

† Saurians with fin-like extremities, under which Mosasaurus is classed without any expression of doubt



Geosaurus Sömmeringii, from Cuvier's figures: *a, b*, part of the head, which has been compressed; some of the sclerotic plates are still left within the orbit, as seen in fig. *b*; *c, d, e*, teeth which had preserved their hard shining brown enamel; *f, g*, vertebræ;—*f* exhibits a part of the column; near the last vertebræ are the remains of the pelvis and femora; *g*, five vertebræ like the first of those in figure *f*. Fragments of ribs in disorder are seen near both sets.

Sömmering, to whom the Count of Reysach gave those *precious fragments*, to use Cuvier's expression (for, in consequence of the nature of the bed in which they were discovered they were not well preserved), published an accurate account of them in the 'Memoirs of Munich' for 1816, accompanied by a lithographic illustration, which Cuvier reduced, and published in his 'Ossemens Fossiles;' Sömmering however thought that the bones belonged to a young individual of the Maestricht animal (Mosasaurus).

The bones were nearly calcined. Near the remains of the Saurian were a flat ammonite four inches in width, a fragment of bluish shell, and a great quantity of small scales, which, according to Sömmering's conjecture, belonged either to fishes or perhaps to the animal itself, if it was a Monitor, or some other lizard with small scales.

Our limits will not allow us to point out the differences between *Geosaurus* and *Mosasaurus*, excepting that they are to be found principally in the teeth and in the vertebræ. The reader who wishes to pursue the inquiry further has only to consult the works above referred to, for the details which have led to the conclusion that the animals are different. The localities given by Hermann von Meyer are the Flötz; Solenhofen slate (Schiefer von Solenhofen); and, with reference to another specimen (with a query), for which he refers to Dekay, 'Ann. of the Lyc. of New-York,' vol. iii., the marl of the green sand in New Jersey (Mergel des Grünsandes in New Jersey).

GERA, the chief town of the three principalities of Reuss-Schleiz, Reuss-Greiz, and Reuss-Lobenstein and Ebersdorf, which are on the western borders of the kingdom of Saxony, is in 50° 52′ N. lat. and 12° 6′ E long. The present town is mostly of modern construction, the old town having been almost entirely destroyed by fire in September, 1780. It is agreeably situated in a valley on the banks of the White Elster, and contains about 860 houses and 9200 inhabitants. The streets are in general broad and at right angles to one another, and embellished with a number of handsome houses. Gera is the seat of government for the Reuss principalities, and of a Protestant consistory. It has a fine town-hall; five churches, independently of the high church of St. John, which is in ruins; a highly esteemed gymnasium attended by between 600 and 700 pupils, who are separated into five classes for such as are intended for a learned or scientific profession, and six for those designed for commercial pursuits, &c.; a seminary for scholars of the higher ranks of society; a school for educating teachers; a house of correction, to which an orphan asylum is attached; two hospitals; a free school, and other scholastic establishments. Gera, from the enterprise and industry of its inhabitants, has been called 'Little Leipzig.' It possesses numerous manufactures, particularly of fine woollens, mixed cotton and silk goods, woollen and cotton yarns, china, earthenware, printed cottons and woollens, oil-cloth, tobacco, carriages, chemical colours, hats, leather, musical instruments, soap, beer, &c. A canal has been made from the Elster, which passes through the town, and is of great use to the manufacturers. The position of Gera secures to it a considerable transit trade with the adjacent countries. The Gera china is made at Schloss Untermhaus, which, together with the princely residences of Osterstein, Köstritz, and Ronneburg, are in the vicinity of the town.

GERA'CE. [CALABRIA.]

GERANIA'CEÆ, a natural order of Exogens, the distinguishing character of which is to have a fruit composed of five cocci or cases, connected with as many thin flat styles, consolidated round a long conical beak, and from which they are separated with violence at the time of maturity by the rolling back of the styles. In many respects they are allied to Malvaceæ, especially in the arrangement of their petals, the tendency to union among the stamens, and in their stipules. It is probable that Tropæolum, although usually looked upon as the type of a distinct order, is only a variation from the typical character of Geraniaceæ. These plants are usually astringent and odoriferous; their smell varying from a disagreeable hircine character to that of great sweetness. The maximum of the order occurs at the Cape of Good Hope under the form of the genus Pelargonium, hundreds of beautiful varieties of which are now favourite objects of cultivation in gardens: these are chiefly bushes. Those species of the order which inhabit Europe are herbaceous plants, with regular flowers and five or ten perfect stamens; a few are handsome enough to be cultivated, but the major part consists of mere weeds. The flowers of the whole order are usually of some tint of purple; it is therefore remarkable that a few species should exist in which the colour is a pure bright yellow; as in Geranium chrysanthum, a native of the South of Europe.

Geranium pratense.
1, a magnified calyx, in the centre of which is the rostrum, or beak, from which the cocci are rolling back.

GERARD, a celebrated translator of the middle ages, was born at Cremona, in Lombardy, in 1114. He early applied himself to philosophical studies, but as they were in a very low condition at that time amongst the Western Christians, he went to Spain, where learning was in a flourishing state amongst the Arabs. He there became thoroughly acquainted with the Arabic, and applied himself particularly to the translation of different works from that language into Latin. Gerard returned to his native town, where he died in 1187, at the age of 73.

His principal translations which have reached us are: 1. *Theoria Planetarum*. 2. 'Allaken de Causis Crepusculorum.' 3. 'Geomantia Astronomica,' which was translated into French, and published under the title of *Géomantie Astronomique*, in 1669 and 1682. 4. The Treatise on Medicine, of Avicenna, known by the name of the 'Canons.' 5. An Abridgment of the Medical Treatise of Rhazis, made by Abouli Ben David. 6. A Treatise on Medicine, by the same Rhazis. 7. 'Practica sive Breviarium Medicum' of Serapion. 8. The Book of Albenguefit 'De Virtute Medicinarum et Ciborum.' 9. The 'Therapeutica' of Serapion. 10. The work of Ishak, 'De Definitionibus.' 11. 'Albucasis Methodus Medendi,' (libri iii.). 12. 'Ars Parva' of Galen. 13. 'Commentaries on the Prognostics of Hippocrates.' All these works have been often printed.

GERARDE, JOHN, a famous herbalist of the time of Queen Elizabeth, was born at Nantwich in Cheshire, in the year 1545, and was educated as a surgeon. He removed to London, where he obtained the patronage of Lord Burghley, who was himself a lover of plants, and had the best collection in his garden of any nobleman in the kingdom. Gerarde had the superintendence of this fine garden,

and retained his employment, as he tells us himself, for twenty years.

His London residence was in Holborn, where also he had a large physic garden of his own, which was probably the first of its kind in England for the number and variety of its productions. It should seem that in his younger days he had taken a voyage into the Baltic, since he mentions having seen the wild pines growing about Narva. He also says of the bay or laurel tree (*Herbal*, pp. 1177, 1223), 'I have not seen any one tree thereof growing in Denmark, Suecia, Poland, Livonia, or Russia, or in any of those wild countries where I have travelled.'

Among the Lansdowne manuscripts in the British Museum (No. cvii., art. 92) is a letter of Gerarde's own drawing up for Lord Burghley to send to the University of Cambridge, recommending the establishment of a physic garden there, to encourage 'the facultie of simpling;' Gerarde himself, whom Lord Burghley calls his servant, to be placed at the head of it: 'So that if you intend a work of such emolument to yourselves and all young students, I shall be glad to have nominated and furnished you with so expert an herbalist; and youselves, I trust, will think well of the motion and the man.' As we read no more of it, it is probable that the scheme did not take effect.

The earliest publication of Gerarde was the catalogue of his own garden in Holborn: 'Catalogus Arborum, Fruticum, ac Plantarum, tam indigenarum quam exoticarum, in horto Johannis Gerardi, civis et chirurgi Londinensis, nascentium,' impensis J. Norton, 1596, 4to.; reprinted in 4to. 1599. The first edition was dedicated to Lord Burghley; the second, after that nobleman's death, in very flattering terms, to Sir Walter Raleigh. A copy of the first edition (of extreme rarity) is preserved in the library of the British Museum, where it proved of great use to Mr. Aiton in preparing his 'Hortus Kewensis,' by enabling him to ascertain the time when many old plants were first cultivated.

In 1597 came out his 'Herbal, or General History of Plants,' printed by John Norton, in folio. The wood-cuts with which it was embellished were procured from Francfort, being the same blocks which had been used for the 'Kreuterbuch,' the German herbal of Tabernæmontanus, fol. Franc. on the Mayn, 1588. A second edition of Gerarde's 'Herbal' was published by Dr. Thomas Johnson, with emendations and corrections, fol. Lond. 1633; and this work continued to be one of the best sources of botanical intelligence, at least to the beginning of the eighteenth century

Gerarde died about the year 1607.

(Pulteney's *Sketches of the Progress of Botany in England*, vol. i., p. 110-125; Chalmers's *Biogr. Dict.*, vol. xv., p. 414.)

GERBERT, MARTIN, Prince-Abbot of St. Blaise, near Freiburg, a learned and laborious writer on music, was born at Horb-sur-le-Necker, in 1722. Attached from his youth to church-music, he cultivated it assiduously, and having determined to write a history of that highly important branch of the art, which he thought intimately connected with his sacred profession, he travelled during three years in France, Italy, and various parts of Germany, for the purpose of collecting materials in aid of his work, which was published in two quarto volumes, in 1774, and entitled *De Cantu et Musica Sacra, à prima Ecclesiæ Ætate usque ad præsens Tempus*. He divides his history into three parts. The first finishes with the pontificate of St. Gregory; the second reaches the 15th century; and the third comes down to nearly the date of his own volumes. Though the illustrious Abbot directed his attention almost wholly to the music of the Catholic church, that is, to the Mass, he liberally notices that of the Protestant establishments, and mentions in favourable terms Dr. Boyce's collection; but being one of those who disapprove the use of fugue, and all such laboured compositions, in ecclesiastical music, he censures the style while he admits the genius and skill of the English composers for the church. Gerbert published in 1784 another work, of equal importance with the former, in two volumes, under the title of *Scriptores Ecclesiastici de Musica Sacra Potissimum*, &c., which is a collection of authors who have written on the subject of his favourite pursuit, from the third century to the invention of printing. These, in number upwards of forty, are arranged chronologically. The work is extremely rare, but M. Forkel has given a useful analysis of it in his History of Music. Gerbert died in 1792. (Schlichtegroll's *Necrology*, vol. ii.)

GERBERT, afterwards pope Sylvester II., was born of poor parents at Aurillac in Auvergne. The time of his birth does not appear to be known; he died in 1003, at a very advanced age.

When young he entered the monastery of St. Gerauld at Aurillac, and in that school commenced his studies. He afterwards visited Catalonia, where he learned mathematics from a Spanish bishop. About 968 he made a journey to Rome, a circumstance which gave him the opportunity of still further satisfying his thirst for knowledge. When Otho I. conferred on him the abbey of Bobbio, Gerbert's industry was not diminished by his promotion. He employed himself actively in teaching, and for several years, while he continued to reside at Bobbio, his fame attracted students from all quarters. Though he kept his abbey till his elevation to the pontifical chair, he gave up his residence in Italy on account of the uneasy life which he led there. From Italy he is said to have gone to Germany, where he became the tutor of young Otho, afterwards the second emperor of that name. From Germany he went to Reims, and was made secretary to the archbishop of Reims, and master of the cathedral-school. It is as a teacher that Gerbert established a reputation which few men since his time have acquired. Under his care the school of Reims became one of the first in Europe, and its high character was maintained for near a century after his death. Among Gerbert's pupils we find the names of Nithard and Remi. In A.D. 992 Gerbert was promoted to the archbishopric of Reims, from which however he was deposed a few years after his elevation. In 998 he received the archbishopric of Ravenna from the emperor Otho III.; and in 999 he was elected to the pontifical chair, which he filled for nearly five years, under the name of Sylvester II.

There is no doubt that Gerbert was a man of great ability and of very extensive acquirements for his age. He was also a most voluminous writer. The Benedictines of St. Maur (*Histoire Littéraire de la France*, tom vi., 577, &c.) have devoted many pages to the consideration of his writings; but they have shown no great discrimination in their criticism. Geometry and astronomy were Gerbert's favourite pursuits; there is or was extant a MS. treatise of his on sun-dials, and he also wrote on the astrolabe. He is said to have been acquainted with the Greek language. His letters, printed by Du Chesne, 1636, at the end of the second volume of his 'Historians of France,' throw some light on the ecclesiastical intrigues and political events of the time.

GERBILLUS. [JERBOA.]

GERFALCON. [FALCONIDÆ; FALCONRY.]

GERMAIN, ST., a town in France in the department of Seine et Oise, distinguished from a multitude of other places of the same name by the epithet *en Laye*. It is on the left bank of the Seine, 14 or 15 miles from Paris on the road to Evreux and Caen. The town had its origin from a monastery founded by King Robert (who reigned A.D. 996—1031), dedicated to St. Germain and St. Martin. There was a royal residence here from a very early period, but the present palace, the chief edifice in the town, was commenced by Francis I. and enlarged by Louis XIV. The town is of considerable extent, containing in 1831 a population of 10,671. It is agreeably situated on a height which commands a beautiful prospect of the valley and the sinuous course of the Seine, with a distant view of St. Denis, Paris, and its environs. The streets are handsome and well laid out, and the houses lofty and well built: there are many antient mansions, once the residence of the lords of the court, before Louis XIV. forsook this place for Versailles. The château, or palace, is a heavy building, chiefly of brick, surrounded by wide and deep ditches; the apartments are handsome. The château was used under Louis XVIII. and Charles X. as a barrack for a company of the Gardes du Corps. The Château Neuf, built by Henri IV. for his mistress 'La Belle Gabrielle,' is now a heap of ruins. The forest or park of St. Germain, surrounded by walls and occupying more than 10,500 acres, is adorned by trees of immense size, and has numerous broad avenues. The royal family resort hither to hunt the deer and other game, of which there is a considerable quantity. A noble terrace, of more than a mile and a quarter in length and nearly 100 feet wide, extends from the palace along the skirts of the forest, and affords to the towns-people an agreeable promenade. In the forest are several small edifices erected at different periods by the kings of France. The town has a

church of modern erection, a new corn-market, and a theatre. It is the residence of a Juge de Paix. The manufactures are of little account; they are of stockings and leather. A yearly fair is held for business; and one a few days afterwards for pleasure: the latter is held in the forest, and attracts a number of visitors from Paris and the surrounding villages. There are many schools; and in the neighbourhood is a subsidiary school for the education of 200 orphan daughters of the members of the Legion of Honour. There are a small public library and an hospital for the sick and aged.

Henri II., Charles IX., and Louis XIV. were born at St. Germain; and Louis XIII. died there. James II. of England and his family found in exile an asylum there. James died at St. Germain in 1701, and his remains were discovered in 1826 in digging the foundations of the new church.

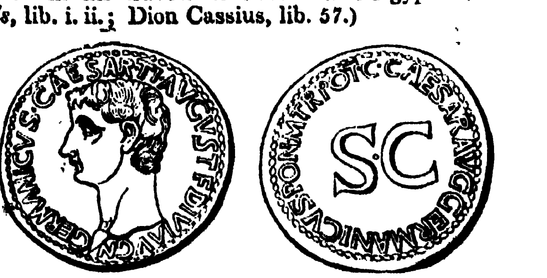
GERMAN'S, ST. [Cornwall.]

GERMAN-BANATE, a considerable district of Southern Hungary, forming, with the Illyrian-Walachian district, the province called the 'Banate, or Hungarian Frontier.' It is the most westerly part of it, lies next the Danube in the south and west, and has the Hungarian counties of Torontal and Temesch for its northern and eastern boundaries. The area is about 1581 square miles; it has one town and sixty villages and hamlets; and its population, which, by the conscription lists, was 61,988 in 1799, and 85,635 in 1815, is now about 116,000, the majority of whom are of the Greek faith. The surface is a complete level, in the centre of which is the great sandy plain of Bieloberdo. It is watered by the Themes, Nera, &c., has extensive swamps, and produces much grain, as well as hemp, vegetables, wine, &c. The woods cover an area of about 11,970 acres. Considerable numbers of horses, oxen, sheep, and swine, are reared. There is only one town in the Banate, Pancsova, at the confluence of the Themes and Danube, in 44° 49′ N. lat., and 20° 38′ E. long.: it is a fortified place and a free town, with extensive lands lying around it, which belong to the municipality. Its population was 6765 in 1806, and it now amounts to nearly 9000: it has two churches, a gymnasium, a mathematical and a normal school, several other schools of an inferior class, and about 950 houses. It is the head-quarters of the Austrian German-Banate regiment, and has a brisk trade with Turkey.

GERMAN OCEAN. [North Sea.]

GERMA'NICUS, CÆSAR, the eldest son of Drusus Nero Germanicus and of Antonia the younger, the nephew of Tiberius, and brother of Claudius, afterwards emperor, was born in the year 14 B.C. Augustus on adopting Tiberius made the latter adopt his nephew Germanicus. At the age of twenty Germanicus served with distinction in Dalmatia, and afterwards in Pannonia, and on his return obtained a triumph. He married Agrippina the elder, grand-daughter of Augustus, by whom he had nine children; among others Caius Caligula, and Agrippina the younger, mother of Nero. In A.D. 12 Germanicus was made consul, and soon after he was sent by Augustus to command the legions on the Rhine. On the news of the death of Augustus some of the legions on the lower Rhine mutinied, while Germanicus was absent collecting the revenue in Gaul; he hastened back to the camp, and found it a scene of tumult and confusion. The young soldiers demanded an increase of pay, the veterans their discharge. They had already driven the centurions out of the camp. Some offered their assistance to raise Germanicus to the supreme power, but he rejected their offers with horror, and left his judgment-seat, heedless of the clamours and threats of the mutineers. Having retired with a few friends to his tent, after some consultation on the danger to the empire, if the hostile Germans should take advantage of the confusion caused by this sedition of the troops, he determined upon exhibiting to the soldiers fictitious letters of Tiberius, which granted most of their demands, and the better to appease them he disbursed to them immediately a considerable sum by way of bounty. He found still greater difficulty in quelling a second mutiny, which broke out on the arrival of legates from the senate, who brought to Germanicus his promotion to the rank of Proconsul. The soldiers suspecting that they came with orders for their punishment, the camp became again a scene of confusion. Germanicus ordered his wife Agrippina, with her son Caius Caligula, attended by other officers' wives and children, to leave the camp, as being no longer a place of safety for them. This sight affected and mortified the soldiers, who begged their commander to revoke the order, to punish the guilty, and to march against the enemy. They then began to inflict summary execution on the ringleaders of the mutiny, without waiting for the order of their commander. A similar scene took place in the camp of two other legions, which were stationed in another part of the country under the orders of Cæcina. Availing himself of the present state of excitement of the soldiers, Germanicus crossed the Rhine, attacked the Marsi, the Bructeri, and other German tribes, and routed them with great slaughter. In the following year, taking advantage of a quarrel between Arminius, the conqueror of Varus, and Segestes, another German chief, he attacked Arminius, and penetrated to the spot where the legions of Varus had been cut to pieces. The bones of the Roman soldiers, which still lay on the ground, were collected and buried by their countrymen. Arminius however fought bravely, and was near defeating a division commanded by Cæcina. In the following campaign Germanicus embarked his troops on board a flotilla which he had constructed or collected for the purpose, and sailing from the island of the Batavi, he landed at the mouth of the Ems, from whence he marched towards the Visurgis, or Weser, where he found Arminius encamped. Two obstinate battles were fought in succession, in both of which Arminius was defeated. Germanicus raised a trophy with this inscription: 'The army of Tiberius Cæsar, having conquered the nations between the Rhine and the Elbe, consecrates this monument to Mars, Jupiter, and Augustus.' After this victory he sent part of his legions by land to their winter-quarters on the Rhine, and with the rest embarked on the Ems, to return by sea; but being surprised by a dreadful storm, his vessels were dispersed, many were lost, and he himself was cast on the coast of the Chauci, whence he returned to the Rhine and placed the legions in winter-quarters. Meantime Tiberius wrote repeatedly to his nephew, that he had earned enough of glory in Germany, and that he ought to return to Rome to enjoy the triumph which he had merited. Germanicus asked for another year to complete the subjugation of Germany, but Tiberius, who felt jealous of the glory of his nephew and of his popularity with the troops, remained inflexible, and Germanicus was obliged to return to Rome, where he triumphed in the following year, A.D. 17. The year after, he was consul for the second time with Tiberius himself, and was sent to the East, where serious disturbances had broken out, with most extensive powers. But Tiberius took care to have a watch over him by placing in the government of Syria Cnæus Piso, a violent and ambitious man, who seems to have been well qualified for his mission, as he annoyed Germanicus in every possible way, and his wife Plancina seconded him in his purpose. The frank and open nature of Germanicus was not a match for the wily intrigues of his enemies. After making peace with Artabanus, king of the Parthians, and calming other disturbances in the East, Germanicus fell ill at Antioch, and after lingering some time he died, plainly expressing to his wife and friends around him his conviction that he was the victim of the treason of Piso and Plancina; whether he meant through poison, or through their annoyances, has been a subject of doubt. His wife Agrippina, with her son Caius and her other children, returned to Rome with the ashes of her husband. [Agrippina the Elder.]

Germanicus was generally and deeply regretted. Like his father Drusus he was while living an object of hope to the Romans. He died A.D. 19, in the 34th year of his age. He is praised for his sincerity, his kind nature, his disinterestedness, and his love of information, which he exhibited in his travels in Greece and Egypt. (Tacitus, *Annals*, lib. i. ii.; Dion Cassius, lib. 57.)



Coin of Germanicus.

British Museum. Actual size. Copper. Weight, 171 grains.

GERMANY extends from 45° 5′ to 57° 50′ N. lat. and

from 6° 20′ to 20° 10′ E. long. It is bounded on the west by the Netherlands, Belgium, and France; on the south, by Switzerland and the Austrian territories in Italy; on the east, by the kingdoms of Hungary, Gallicia, Poland, and Prussia; and on the north, by the Baltic. Its area is stated to be 284,000 square miles, or about twice and a half the area of the British islands.

The surface is divided into four distinctly marked districts, two plains and two mountain-regions. One of the plains is low, and rises only a little above the level of the sea; the other attains a considerable elevation. Between the two plains extends a mountain-region, whose summits in no part attain the snow-line, which in this parallel is calculated to be about 6000 feet above the sea-level. To the north of this region extends the low plain, and to the south of it the elevated plain, which on the east and west is enclosed by mountainous tracts belonging to that region. The southern boundary of the elevated plain is formed by the Alps, which constitute the fourth natural division of Germany.

The *low plain* is only a small section of the great plain which extends nearly over the whole northern part of the old continent. This section occupies the northern portion of Germany, which lies on the southern shores of the North and Baltic Seas, and extends to the peninsula of Jutland. Its length, from the boundary of the Netherlands and the Rhine to the borders of Russia, including the kingdom of Prussia, is nearly 600 miles; but its width varies, being, on the west of the Elbe, on an average about 160, and to the east of that river about 300 miles. The line which separates it from the mountain-region south of it may be determined in the following way:—Beginning on the west with the bank of the Rhine, it follows the course of the river Lippe (51° 40′ N. lat.) as far as the town of Paderborn, and thence follows a line drawn from that town in a north-eastern direction to Hanover, and so on through Brunswick to Magdeburg on the Elbe. From Magdeburg it runs nearly south to Halle on the Saale, and thence south of Leipzig to Dresden. From the capital of Saxony it extends due east to Breslau on the Oder, from which town it follows the course of this river nearly to its source, and to the Carpathian mountains, which constitute its southern boundary farther eastward.

There is probably no tract of country in Europe of equal extent which has a less fertile soil than this plain. Even the steppes of Southern Russia to the north of the Black Sea have a better soil, but as they have not the advantage of abundant rains, which are enjoyed by the German plain, the latter is much better cultivated and more thickly inhabited than the Russian steppes. This plain is supposed to have been once covered by the sea. Its substratum is formed by limestone, chalk, gypsum, and sandstone, which are covered by loam, clay, and sand, to an average depth of 200 feet. If this country were situated under a tropical climate and deprived of the abundant rains and snow which annually descend upon it, the surface would resemble the Sahara or the great Indian plain.

Though sterility is the general character of this plain, still there is a remarkable difference between the countries west and east of the Elbe river. On the west of that river the plain is nearly destitute of trees. It presents a succession of tracts covered with heath and juniper bushes, and of moors which mostly consist of turf, a hundred feet deep and upwards. Each of these tracts occupies an extent of 12 or 15 miles square, and the succession is sometimes interrupted by tracts entirely covered with sand and nearly without vegetation. A sandy tract of this description, which has been particularly described by the German geographers, is called the Huimling. It extends along the eastern banks of the river Ems, between the mouths of the rivers Hase and Leda, is at a considerable elevation above the surrounding country, and at its base is nearly 24 miles in circumference. All over this plain cultivable ground occurs only in the shape of oases which are at great distances from one another. The soil produces on an average only three or at the utmost four times its seed. To complete the picture of this plain, we shall add a description of those districts which are distinguished by fertility. The rivers run in depressions from 100 to 200 feet below the level of the plain. Along their banks there are bottoms with a fertile soil, which are covered in their natural state by forest trees, and when cultivated produce good crops. These bottoms vary in width, according to the volume of water in the rivers. Along the great rivers (Weser, Elbe), they are from three to six miles wide, where these rivers issue from the mountain tracts in which they originate; but farther down they widen to twenty or thirty miles and even more. Where the rivers approach the sea, the bottoms are united with the marshes which line the shores of the North Sea these marshes are not of great extent, being only five or six miles across on the average, but they do not yield in fertility to any tracts in Europe. Being below the level of the sea at high tides, it is necessary to protect them by dikes from its invasions. Nearly in the middle of the plain occurs another fertile tract, enclosed by two ridges of high hills, which issue from the mountain-tract farther south, on both sides of the parallel of 52° N. lat. The more northern of these ridges, called the Süntel, rises to the south of the town of Hanover, whence it runs westward, and south of Minden forms the Porta Westphalica, where it is broken through by the river Weser. To the west of this river it continues westward, and terminates about six miles from the river Ems. This ridge hardly reaches an elevation of 1000 feet above the sea. The southern ridge has the name of Egge east of Paderborn, and runs there south and north, but north-east of that town it turns west-north-west, and continues in that direction, approaching gradually the Süntel Hills, which however it does not join, as it terminates about three miles from the Ems, opposite Schüttorf, and about the same distance from the western extremity of the Süntel Hills. This ridge is known by the name of the Teutoburger Wald, or Osning. The valley between these two ridges is of considerable fertility; its eastern portion forms the principality of Lippe Detmold, and its western belongs to the Prussian province of Westphalia and the Hanoverian province of Osnabrück. That portion of the plain which is situated to the south of this valley contains a much larger portion of arable land than that which is north of it. The country between the Weser and Elbe does not differ in its general character from that west of the Weser in its northern districts, but towards the south it partakes more of the peculiar nature of the eastern portion of the plain, being mostly covered with forest trees of the pine kind. Such is the heath of Lüneburg, which occupies the whole space between that town and Hanover.

That portion of the plain which lies east of the Elbe has a somewhat different character. Tracts covered with heath and moor occur here also, not contiguous, but separated from each other by great intervals of sandy surface. These sandy tracts however are not destitute of vegetation, nearly all of them being covered by various kinds of pine, which give the soil a greater degree of solidity. Still all lands of this description are only cultivated in a comparatively few and favoured places, and the crops are very scanty; but this portion of the plain contains a greater number of fertile tracts, which in some places are of considerable extent. The bed of the rivers is less depressed below the level of the plain, and the rich lands along their banks have a greater width. The marshes which are adjacent to such lands, and nearly on the same level with them, have been drained, and changed into meadows and fields. Along the shores of the Baltic no marshes occur, but the larger rivers, especially the Vistula and Niemen, form deltas at their mouths, whose alluvial soil is of great fertility, and can hardly be exhausted by successive crops. Besides these there are several fertile tracts at some distance from the rivers, whose soil is a heavy loam of considerable fertility. Such lands are more common between the Elbe and Oder than between the last-named river and the Vistula, and still more so between this river and the Niemen.

Through the northern part of this plain a higher tract may be traced, which in general runs west and east, but with two great bends. It begins on the west at Oldeslo in Holstein, whence it runs east-south-east nearly in a straight line to Schwedt on the Oder, where it is about seventy miles from the sea. East of that river it continues due east to Arendswalde, and then inclines to the north, gradually approaching the sea. Some distance west of Danzig it takes a short south-east course, and then again due east, terminating on the banks of the Niemen, near Grodno. This tract of high ground forms the watershed between a great number of small rivers which fall into the Baltic and many others, with a much longer course, which run off to the southward, and increase the waters of the Elbe, Oder, and Vistula. It is also remarkable for the immense number of small lakes which occur on its higher parts or near them. Some of these are lakes of considerable extent, as the lake

of Schwerin, near the western extremity, and the lake of Spirding, towards the banks of the Niemen. On the northern side of this high ground we find those numerous erratic blocks or boulders which have attracted the attention of geologists.

The *mountain region of Central Germany* extends to the south of the low plain, and encloses the elevated plain on the east, north, and west. That portion of it which is to the east of the elevated plain may be called the mountain-system of Bohemia, because it encloses that kingdom on all sides. That which extends to the north of the elevated plain we shall call the Central mountain-system of Germany; and the ranges enclosing the elevated plain on the west, the Rhenish mountain-system, because they run parallel to the middle course of the Rhine.

The Fichtelgebirge and the Forest of Bohemia, of which an account is given under those respective articles, form the western branches of the mountain-system of Bohemia. At the south-eastern extremity of the Forest of Bohemia, the mountain-range turns first to the east and afterwards to the north-east, in which direction it continues until it reaches 50° N. lat., where it meets another and higher range, extending in a different direction, from south-east to north-west. The last-mentioned range is the Sudetes, or Sudetsch mountains, and the former the Moravian mountains. The Moravian mountains, which extend about 160 miles in length, and form the watershed between the Danube and Elbe, are of very moderate elevation; hardly any part of them exceeds 3000 feet, and as the basis on which they stand can hardly be less than 2000 feet above the sea-level, they have not the appearance of mountains. Their higher parts also extend in plains, and their declivities sink with a gradual descent, so that the country (Moravia) which is covered by the south-eastern offsets is more like a plain with a strongly undulating surface, than a mountain-region. Several of the offsets to the north-west (into Bohemia) are of great elevation.

The Sudetes or Sudetsch mountains begin about seventy miles south-east of the point where they are joined by the Moravian mountains, at the sources of the river Oder. They are not connected with the Carpathian mountains, but separated from that system by a wide elevated valley, in which the river Oder flows. The southern portion resembles in height and formation the Moravian mountains, and both are covered with extensive forests. Where both ranges join, the Sudetes begin to rise higher; and the Glatzer, or Grulicher Schneeberg, attains an elevation of about 4780 feet. Farther to the north-west the range rises still higher, and is known by the name of the Riesengebirge, or Giant Mountains. The Grosse Rad (Great Wheel) rises to 4950, the Schneekappe (the Snow-cap) to 5320, and the Sturmhaube to 4800 feet above the sea. This range, which, from the sources of the Oder to those of the river Neisse in Lusatia, extends upwards of 130 miles, and whose average width is about 35 miles, consists of granite, gneiss, mica-slate, sandstone, porphyry, and limestone. Its higher parts are formed of immense rocks, broken down in all directions, and split by deep rents; they are mostly bare. Pine-forests occur in some tracts, and others are used as pasture-ground; but in most parts the vegetation is limited to a few mosses. The more gentle declivity towards Bohemia is better wooded, and has better pastures than the steeper descent towards Silesia. Snow lies on the summits of these mountains from October to June.

From the sources of the river Neisse in Lusatia the range turns suddenly to the west, and is accordingly with some reason considered as a separate range, though sometimes it is viewed as a portion of the Sudetes. It is called the Mountains of Lusatia, or the Wolish Kamm. Its eastern portion, which has a considerable elevation, contains the Hochwald, which rises to 2500 feet; and the Laushe or Spitzberg, which attains 2624 feet. Its highest parts extend in plains, intersected by narrow and steep valleys. The western portion near the Elbe does not rise to any great height, and is often interrupted by wide valleys, so as not to form a continuous ridge. On account of its natural beauties, it is called the Saxon Switzerland (Sächsische Schweitz). The most western mountain is the Lilienstein, 1312 feet above the sea; it rises with a steep declivity from the very bed of the Elbe. On the other side of the Elbe, and opposite the Lilienstein, begins that range which is called the Erzgebirge (Ore Mountains), and which extends to the Fichtelgebirge. [ERZGEBIRGE.]

The Fichtelgebirge and the Erzgebirge are the last ranges that belong to the mountain-system of Bohemia; the mountainous countries to the north-west of them are parts of the Central mountain-system of Germany. This system extends to the very banks of the Rhine. Its average breadth rather exceeds 100 miles; but the whole region does not extend in the same direction. The eastern portion lies south-east and north-west, and the western, south-west and north-east, so that they meet nearly at a right angle, about 50° 30′ N. lat., and 11° E. long. The southern border of this region is formed by one nearly continuous range, which however bears four different names, Frankenwald, Thüringerwald, Röngebirge, and Spessart. The Frankenwald and the Thüringerwald constitute one range, which lies in the same direction, and might be comprehended under one name, as it is indeed by some German geographers, who calls the whole range Thüringerwald. It begins at the Fichtelgebirge, and extends nearly in the direction of the Forest of Bohemia, bending only a little more to the west. The length of this range somewhat exceeds seventy miles, and its breadth varies from five to eighteen miles. The south-eastern half, or the Frankenwald, hardly rises to more than 2000 feet above the sea, and descends on each side with a gentle slope. Its summit is a narrow but nearly level plain. The Thüringerwald, or north-western portion of the range, has likewise in most places a narrow level plain on its summit, but some points rise much above this level. The Beerberg rises to nearly 3300, the Schneekopf to 3248, and the Inselsberg to nearly 3000 feet; some other points are not much lower. The mean elevation of this range is very little short of 2500 feet. The declivity towards the north-east is very steep, and furrowed by narrow, short, and transverse valleys; but towards the south-west it descends gently, forming long and frequently wide and fertile valleys. The whole range is covered with woods, consisting chiefly of pine-trees. It is mostly composed of granite, gneiss, mica-slate, clay-slate, and hornblende. As the upper part of the range is a level plain, a road is formed along it, which is called the Rennsteig or Rennweg, and generally runs on the watershed between the rivers which fall into the Elbe and into the Werra, a branch of the Weser.

The Röngebirge, or Rön mountains, are separated from the northern part of the Thüringerwald only by the valley of the Werra; but they cannot be considered as its continuation, since they extend north-north-east and south-south-west, forming with the Thüringerwald an angle of less than 80 degrees. It is of comparatively small extent, being only 24 miles long, and on an average 5 miles wide. It divides the waters which flow into the Fulda and Werra from those of the Franconian Saale, which empties itself into the Main. Its mean elevation seems rather to exceed 2000 feet, and some summits rise several hundred feet higher. The Kreuzberg attains 3000 feet, and the Dammersfeld nearly as many; the Eierhunk, 2824 feet. Its summit is mostly a level plain, which slopes down to the north-west gradually, but descends rapidly to the south-east. This range is of volcanic origin, consisting of lava, basalt, porphyry, and tufa, and presents a very dismal aspect, being only wooded on the southern and south-eastern declivity: its summit is covered with extensive moors.

The Spessart extends from the south-western extremity of the Rön mountains, from which it is only separated by a depression, to the most western bend of the river Main as far as Miltenberg. The narrow valley of that river separates it from the Odenwald. Its length may be about 24 miles, and its mean breadth about 10. It does not present a continuous ridge, but consists of a great number of hills, standing in different directions on a base which rather exceeds 1200 feet above the sea. The highest summits are the Geiersberg, 2016 feet, the Hockenhöhe, 1900 feet, and the Granatenberg, 1800 feet above the sea-level. Towards the west the declivities are very gentle, but towards the east rather steep. This range consists of granite, gneiss, mica-slate, and limestone.

The Thüringerwald, the Rön mountains, and the Spessart, form the northern boundary of the elevated plain of Bavaria. The base on which they stand has towards the east an elevation of more than 1500 feet, but it lowers toward the west to 1200 feet. From this elevation the ground declines through the whole central mountain region, at first rapidly, and afterwards more gradually. In the middle of it the base is only 800 feet, and towards its northern

boundary rather less than 600 feet high. Accordingly, we find that nearly all the watercourses, as the Saale, Werra, Fulda, and many others, run off towards the north.

The northern boundary of the central mountain region is not so strongly marked by nature as the southern, except on the east, where it is formed by the Harz mountains. This mountain-range, the most northern in Germany, occupies an area of nearly 800 square miles, between 51° 30′ and 52° N. lat., and 10° and 11° 30′ E. long. It lies nearly parallel to the Frankenwald and Thüringerwald, and about 60 miles from it, and runs east-south-east and west-north-west. Its length is about 55, and its mean width probably does not exceed 18 miles. On the north and south the mountains rise with a rather steep ascent; on the east they sink into an elevated plain, and on the west pass gradually into the hilly tract which joins it in that direction. No continuous ridge can be observed. The range consists of an assemblage of irregular mountain-summits, with generally level tops, covered with earth and with trees. A few of the summits, which consist of granite and hornblende, are bare, and rise higher and with a steep ascent. The valleys between them, some of which are wide and others narrow, lie in every direction. The forests are mostly composed of pine, except to the east, where the mountains are lower, and covered with other trees, as elms, ash, &c. The higher parts are covered with snow from October to May. The nucleus of the Harz is granite, which however is generally covered with porphyry, grauwacke, clay-slate, limestone, gypsum, and sandstone. In the western districts are rich lead-mines, which produce a considerable quantity of silver; in the eastern iron ore is abundant. The highest summits are—the Brocken, 3740 feet, the Königsberg, 3420 feet, the Bruchberg, 3420 feet, the Achtermanns-höhe, 2880 feet, and the Warmberg, 3080 feet above the sea-level. There are some remarkable caverns in it, as the BAUMANNS-HÖHLE. A line drawn from Ilsenburg over the Brocken, the Achtermanns-höhe, and the Bruchberg, divides the whole range into two parts, of which the eastern and lower is called the Lower Harz, and the western and higher the Upper Harz. The same line separates the waters which run to the Elbe and Weser respectively.

The connexion between the Harz mountains and the Thüringerwald is formed at the western extremity of both ranges by an elevated table-land lying south of the Harz, called the Eichsfeld, whose surface is perhaps 1500 feet above the sea-level. From its southern extremity issues a range, which rests on a base about 800 feet high, and runs southward to the Inselsberg in the Thüringerwald, under the names of Hainich, Finne, and Dün. This range has a flat level on its highest parts, but some summits attain an elevation of 1400 or 1800 feet. The hilly country east of this connecting range towards the plain of Saxony is generally fertile.

The western extremity of the Harz mountains is connected with a hilly country, which extends to the Weser, and as far north as Minden. The hills which occupy this district rarely rise to the elevation of mountains, except in the Solling, where the Moosberg attains 1680 feet. This hilly country continues west of the Weser to the Egge, east of Paderborn, which is a narrow range, rising in its highest summits to about 2000 feet, and overgrown with fine forest trees. At its southern extremity (about 51° 30′ N. lat.) the Egge range turns to the west, and runs to the very banks of the Rhine between the rivers Ruhr and Lippe. This latter range is called on the east Aardei, and towards the west Haarstrang. It is a narrow ridge, the most elevated parts of which probably do not exceed 1500 feet, and its mean elevation not 1000 feet. It consists of bare rocks. The Haarstrang, the Egge, the hilly country between the Egge and the Harz, and the last-mentioned range, form the boundary between the low plain and the central mountain-region of Germany. Along this line, towards the north, extends a tract with an undulating surface. It is of inconsiderable width (from 4 to 8 miles), but fertile.

The western declivity of the central mountain-region is formed by three table-lands, of a very uneven surface, which begin on the very banks of the Rhine, and rise gradually as they advance towards the east. The most northern, which is contiguous to the ridge of the Haarstrang to the south, is called the Sauerland, which extends as far southward as the river Sieg, a tributary of the Rhine. On a base of about 500 feet rise several ridges and summits, a few of them to 2500 or 2800 feet. It has mostly a stony surface of very indifferent quality, but it contains copper, coal, and immense quantity of iron-ore. The numerous articles of hardware from this district are well known in Germany. The hills do not advance close to the Rhine, but are separated from the river by a level tract of great fertility.

South of the Sauerland extends the Westerwald, between the rivers Sieg and Lahn. Its western border comes close up to the Rhine, south of Bonn, and is known under the name of the Siebengebirge (Seven Mountains). In some places it extends in level flats, which may be from 500 to 800 feet above the sea; in others it rises in single summits, or ridges. Some of the summits are nearly 2800 feet above the sea. The highest summits in the Siebengebirge are the Löwenberg (1550 feet), and the Oelberg (1550 feet). This part of the Westerwald exhibits some traces of volcanic action. This region is composed of grauwacke, basalt, lava, limestone, and clay-slate. Its soil is stony and dry, and very little adapted for agriculture; a few places only are wooded. Coal is abundant in this tract.

The third hilly plain, which occupies nearly the whole space between the rivers Lahn and Main, is called the Taunus. It very much resembles the Westerwald in its structure, except that it is less elevated and more fertile. The highest summit is the Feldberg, which attains 2760 feet. The Taunus sinks with a steep descent towards the Main and Rhine, but gradually towards the Lahn on the north. It also advances close up to the Rhine, and, with the Westerwald, renders the scenery on that river so interesting between Bonn and Mainz. The Taunus does not join the Spessart, being separated from that range by an extensive hilly tract, which is generally very fertile, especially the Wetterau.

The interior of the central mountain region, or the countries enclosed by the mountain-ranges which we have described, presents nothing but a succession of valleys and high hills. The valleys are frequently wide, but generally of only moderate fertility. The hills have in general a gentle descent, and many of them are cultivated to some height. No hill rises to the elevation of a mountain except the Vogelsberg, north of the Spessart, and west of the Rön mountains, which consists of basalt and lava. It extends about 20 miles from east to west, and 15 from north to south. Its highest part, called the Oberwald, is a level plain, nearly 10 miles in length, and more than 2560 feet above the sea-level; in summer it is always covered with fogs, and in winter with snow. It is surrounded by many summits, which rise to 2300 or 2400 feet. This mountainis-mass is only cultivated in the narrow valleys towards its lower declivities.

The system of the Rhenish mountains, which enclose the elevated plain on the west, rise at their northern extremity, at no great distance from the place where the river Main joins the Rhine, a few miles south of the town of Frankfort. They begin with low hills, which however soon rise to mountains, forming a continuous range, and extending along the bank of the Rhine, south-south-west to the innermost angle of the great bend of the river which is opposite to Basle. The continuity of this range, which extends over a tract of about 180 miles in length, is only interrupted by the narrow valley through which the river Neckar flows. Owing to this circumstance the range is known under two names, the northern being called Odenwald, and the southern Schwarzwald, or Black Forest. The Odenwald advances close up to the Main, between Ostheim and Miltenberg in Bavaria, and is here separated only by a narrow valley from the Spessart, which rises on the other side of the river. It occupies the whole space between this river and the Neckar, whose banks it constitutes between Ebersbach and Heidelberg in Baden. Its length from north to south is about 35 miles, and its width probably not less than 25 miles. It is composed of granite, which is partly covered with limestone or sandstone. Some very high tracts are uncultivated, but by far the greatest portion is covered with trees, or well cultivated, especially towards the east, where it descends with a much more gentle slope than on the side towards the Rhine and in the valleys. The valleys run mostly longitudinally. The single summits lie in the direction of south and north. The highest summit, which is near its southern extremity, is called the Katzerbuckel, and rises to 2320 feet. Farther north are the Neukircher Höhe (1936 feet), the Trumm (1930 feet), and the Malchen, or Melibocus, 1700 feet above the sea. Along

this range runs the Bergstrasse, or mountain-road, to the west of which a plain extends to the Rhine: this plain is generally fertile.

The Schwarzwald, or Black Forest, occupies the remainder of the 180 miles, extending from Ebersbach and Heidelberg, on the Neckar, to Rheinfelder and Waldshut, on the Rhine, over a space about 150 miles long, and varying from 25 to 40 in breadth. About one-third of the range, the most northern portion between Heidelberg and Pforzheim, consists rather of high hills than mountains, and the greater part of it is cultivated to a considerable elevation. The Schwarzwald, south of Pforzheim, forms an enormous mass of rocks, whose higher parts extend in rather level plains, from 2000 to 3000 feet above the level of the sea. On this surface rise a small number of summits in the form of cones. Its nucleus consists of granite, which is frequently covered with porphyry; at its base and on its summits sandstone occurs in many places. Towards the east it descends in long slopes which terminate on elevated ground; but towards the Rhine on the west its declivity is rapid, leaving between it and the river a level space varying from 4 to 20 miles in breadth. On the south, between Rheinfelden and Waldshut, it terminates in a steep declivity on the very banks of the Rhine. The highest summits occur towards the south. The Kandel, north-east of Freyburg, attains 4160 feet; the Feldberg, south-east of Freyburg, 4900 feet; the Belcher, 3600, and the Blaner, 3840. It derives its name from the pine-forest which covers its declivities and higher parts. The soil is rather sterile, and very little adapted to agriculture, and the climate is very cold. Its inhabitants, who are tolerably numerous, gain their livelihood by working in the mines (iron and lead, copper, bismuth, and zinc), and by preparing the produce of the forests for the market; they rear also cattle. In the narrow valleys, which in general run longitudinally, fruits are raised in abundance.

The Elevated Plain or the table-land of Bavaria, which extends between the Schwarzwald and Odenwald on the west to the Böhmerwald on the east, as far north as the Thüringerwald and Rön mountains, is bounded on the south by the Alps, from which it is divided by a line running from Lindau on the Bodensee, or lake of Constance, nearly east through Kempten and Benedictbaiern to Neubaiern on the Inn, and then following the course of this river to its mouth at Passau. Its length from north to south is about 180 miles, and its mean breadth probably exceeds 120 miles. The western portion of this plain has a much more uneven surface than the eastern. Between the sources of the Neckar and Danube a high ground begins on the eastern declivity of the Schwarzwald, and extends in a north-eastern direction through the plain, until it sinks down to its level at the sources of the river Iaxt, about 90 miles from its origin. This high ground separates the waters which fall into the Neckar and into the Danube, and is called the Rauhe Alp. Consisting of the same kind of limestone which constitutes the Jura mountains in the western districts of Switzerland, it is considered as a prolongation of that range, which is supposed to be interrupted by the valley of the Rhine between Schaffhausen and Basle. On the banks of the Danube it has not the appearance of a mountain-range. It rises as a gently inclined plain continually for 12 or 16 miles and more, until it has attained its greatest elevation, which on an average may be 2500 feet, when it sinks in a steep descent towards the rivers which fall into the Neckar. The highest summits occur near the sources of the Danube and Neckar, where the Delingerberg, the Schafberg, and the Hohenberg attain about 3300 feet; but farther east the few summits that occur hardly rise a few hundred feet above the inclined plain. The soil of this plain is extremely dry, as the limestone quickly absorbs the water. It has on it some small woods, mostly of beech, but the greater part is covered with a coarse grass, affording only pasture for sheep. The country south of the Rauhe Alp, as far as the foot of the Alps, is from 1800 to 2000 feet above the level of the sea. It is traversed by numerous ridges of low hills, running south and north, but the wide valleys which lie between them are fertile, well peopled, and cultivated, though their cold climate does not favour the growth of several productions which succeed in the districts north of the Rauhe Alp.

That portion of the elevated plain which extends between the Rauhe Alp and the Schwarzwald, and is mostly drained by the Neckar and its branches, has a strongly undulating surface, but the hills rarely rise to a considerable height. The valleys are wide and fertile, and as their elevation above the sea on an average does not exceed 1000 feet, and most of them are well sheltered, they are productive in wine and in every kind of grain. This tract is considered the most pleasant and fertile part of Germany, except the valley of the Rhine.

The eastern portion of the elevated plain is divided into two parts by the Danube. On the south of that river there are many level plains which extend frequently 30 miles in length. Most of them have a fertile and well cultivated soil; others are disfigured by swamps and morasses. [Bavaria, vol. iv., p. 50.] Towards the foot of the Alps these plains are from 1800 to 2000 feet above the sea, but towards the Danube they sink down to 1200 or 1000 feet. Some isolated rocks rise with a steep ascent a few hundred feet above it.

On the north of the Danube the country begins to rise immediately from the banks of the river, and continues rising for several miles, till it has attained an elevation of 1400 to 1500 feet above the sea-level: it then extends in a nearly level plain, which is from 20 to 30 miles across and over which the line of separation runs between the streams that descend to the Danube and the Main. On the north-east, towards the foot of the Fichtelgebirge, about the sources of the rivers Pegnitz, Vils, and Roth (Red) Main, the plain rises to 2000 feet in the table-land of Thurndorf. This high plain, which is called the High Ground of Franconia (Der Franckische Landrücken), is rather cold in winter, but its soil is far from being sterile, though some sandy tracts occur, and others are covered with extensive woods. The northern slope of this High Ground is very gradual, occupying a tract about 30 miles in width, and terminating on the bank of the Main at an elevation of 800 to 600 feet above the sea. This tract, which is of greater fertility than the High Ground, produces rich crops of grain; towards the Main good wine is made. Its surface is rather undulating, and a few ranges of hills occur, as the Steigerwald near the banks of the Main, whose highest summit, called the Schwammberg, attains 2336 feet. The northern part of the plain, which occupies the country north of the river Main, and extends into the angle formed by the Rön mountains and the Thüringerwald, is much more hilly. It is mostly covered with extensive forests, but it contains also some wide and fertile valleys.

The fourth natural division of Germany comprehends the Alps and their numerous valleys, of which a description is given under Austria, vol. iii., p. 130-132.

That part of Germany which lies on the left bank of the Rhine contains level tracts only along the river, the greater part of it being occupied by mountain-ranges which partly constitute the northern extremity of the Vosges mountains, and partly the eastern districts of the Ardennes. The Vosges enter Germany as a broad-backed range, and descend rapidly towards the flat tract, which, with a mean breadth of eight or ten miles, separates them from the Rhine; they lower gradually towards the west, where they terminate in a flat level of moderate extent. The highest summit in this part is the Kalmuck, which attains about 2200 feet. The Vosges terminate properly at Kaiserlautern, where a valley, about 50 miles long and 4 wide, extends from the Rhine to the Saar; its mean elevation is 800 feet above the sea, and it is partly covered with moors. North of this valley lies a rather extensive mountain-tract, which may be considered as a continuation of the Vosges. Its eastern part is known by the name of Donnersberg (thunder-mountain), whose highest summit, the Königstuhl, attains an elevation of 2240 feet; west of the Donnersberg is the Hochwald, the Idarwald, and north-west of it the Hundsrück. The Hochwald forms the highest part of the whole, rising in the Walderbsenkopf to nearly 2700 feet. The Iderkopf, in the Iderwald, attains [illegible]6 feet; and the Oppeler Höhe, in the Hundsrück, 2112 feet. The last-mentioned range terminates in steep rocks on the very banks of the Rhine, between Bingen and S. Goar, opposite the Taunus. This mountainous region consists mostly of grauwacke and slate, and its upper part presents an undulating but bare surface; some parts are well wooded. The valleys along the water-courses are of moderate fertility, but cultivated with great care. This mountain-region occupies the whole tract between the valley of the Rhine and the rivers Moselle and Saar.

On the other side of the Moselle is the Eifel, which may

be considered as a part of the Ardennes, and is only separated from the Hochwald and Hundsrück by the deep valley in which the Moselle runs. It extends on the very banks of the Rhine as far north as Bonn, and its descent towards the river is exceedingly steep between Andernach and Sinzig. Westward it advances about thirty miles, until it joins the Ardennes. This extensive rocky mass has lately attracted the attention of geologists. Its upper surface, which appears rather as a plain of a very rugged surface, on which several summits rise to some height, is partly covered with sand and swamps, and partly with pumice-stone and lava. There are numerous depressions, mostly filled with water, which have been recognised as extinct volcanoes. From one of these depressions, called the lake of Laach (750 feet above the sea), a lava-tract extends five miles in length, and nearly three miles in width, to the small river Nette. This mountain-mass consists mostly of limestone, slate, and basalt. In some parts it is covered with stunted trees, and in others is a complete desert. The highest summits upon it are the Hochacht, composed of basalt, which attains 2336 feet; the Schneifel is 2940 feet, and the Ernstberg is about the same height. The north-western part of the Eifel is the Hohe Veen (called by the French Haut Fanges), a mountain plain, extending about fifteen miles in every direction. Its surface rises and lowers imperceptibly, and very few summits occur on it; but as its elevation is from 1800 to 2200 feet above the sea-level, it is very sterile, mostly covered with swamps, and nearly all the year round enveloped with fogs, so that it is dangerous to cross it.

The Eifel and the Höhe Veen constitute the southern boundary of the low plain on the west of the river Rhine. In this part the plain extends over Belgium and the southern provinces of the Netherlands. Though the districts united to the Netherlands are not much superior in fertility to that part of the low plain which lies on the other side of the Rhine, those which form Belgium and which belong to Germany exhibit a different character, being fertile to a considerable degree.

Climate.—The climate of the different parts of Germany differs in no great degree, if we except the countries situated on the southern declivity of the Alps and its valleys. At Trieste, on the Adriatic Sea, the mean annual temperature is 58°; but north of the Alps, the temperature is nearly equal all over Germany. Though the northern districts are seven or eight degrees farther north than the southern, the difference of temperature due to this cause is compensated by the much higher elevation of the southern districts. The mean annual temperature varies only between 45° and 50° of Fahrenheit (that of London is 48°), as may be seen in the following table:—

Königsberg, in Prussia	43·5°
Sagan, in Silesia	46·5
Ingolstadt, in Bavaria	45·5
Breslau, in Silesia	46·2
Iena, in Saxony	46·3
Ratisbon, in Bavaria	46·4
Tübingen, in Würtemberg	46·4
München, in Bavaria	47·0
Erfurt, in Prussia	47·1
Göttingen, in Hannover	47·8
Berlin, in Prussia	49·2
Prag, in Bohemia	49·3
Karlsruhe, in Baden	49·7
Frankfort, on the Main	50·0
Stuttgard, in Würtemberg	49·7
Trier, in Rhenish Prussia	50·0
Würzburg, in Bavaria	50·2
Manheim, in Baden	49·7
Wien, in Austria	50·8
Düsseldorf, in Rhenish Prussia	50·8

In the greatest degree of cold which has been experienced, the thermometer sunk to 31° below zero, and in the greatest degree of heat it rose to 95°. The countries along the banks of the rivers Rhine and Main enjoy the mildest climate, and here the almond-tree and the chesnut-tree succeed very well. Vines do not grow north of 51° N. lat., unless peculiar care is taken to shelter them.

The low plain, which lies exposed to the winds that blow from the northern seas, has a much moister and more variable climate than the interior, which, owing to its greater elevation, is much drier and less subject to sudden and frequent variations. The quantity of rain which annually falls varies greatly with the localities of places. It amounts at Wittenberg to eighteen, at Berlin to twenty-one, at Ulm to twenty-eight inches.

(Gutsmuth, *Deutsches Land;* Hoffmann's *Deutschland und seine Bewohner;* Stein; Hörschelmann.)

For the present political divisions of Germany, see EUROPE, vol. x., p. 89.

Antient Germany.—The word Germania was employed by the Romans to designate a country of greater extent than modern Germany. They included under this name all the nations of Europe east of the Rhine and north of the Danube, bounded on the north by the German Ocean and the Baltic, including Denmark and the neighbouring iaslnds, and on the east by the Sarmatians and Dacians. It is difficult to determine how far Germany stretched eastwards. According to Strabo (vii., c. 1) Germanic tribes dwelt nearly as far as the mouths of the Borysthenes (Dnieper). The northern and north-eastern parts of Gaul were also known under the name of Germany in the time of the emperors, after the province of Belgica had been subdivided into *Germania Prima* and *Germania Secunda.* [FRANCE, vol. x., p. 423.]

The Greeks and Romans had very little knowledge of Germany before the time of Julius Cæsar, who met with several German tribes in Gaul, and crossed the Rhine more than once, rather with the view of preventing their incursions into Gaul than of making any permanent conquests. His acquaintance was however limited to those tribes which dwelt on the banks of the Rhine. Under the early Roman emperors many of these tribes were subdued, and the country west of the Visurgis (Weser) was frequently traversed by the Roman armies. But at no period had the Romans any accurate knowledge of the country east of this river; and it is therefore difficult to fix with certainty the position of the German tribes, particularly as the Germans were a nomad people. Some parts of Germany were inhabited by the Gauls, who were, according to Cæsar (*Bel. Gal.*, vi. 24) the more warlike nation in early times. Two great countries of Germany, Bohemia (Boihemum), and Bavaria (Boioaria), derived their names from the Boii, a Gallic tribe.

The name of Germani was first applied by Cæsar to the whole nation east of the Rhine, though it properly belonged only to those tribes which he conquered in Gaul. Tacitus states (*Germ.*, c. 2) that the first tribe which crossed the Rhine were the Tungri, who were afterwards called Germani, which is supposed to be the same as *Wehrmann;* that is, 'man of war.' It is doubtful whether the Germans themselves employed any one name to designate the whole nation. Tacitus (*Germ.*, c. 2) divides them into three tribes: 1. Ingævones, bordering on the ocean. 2. Hermiones, inhabiting the central parts. 3. Istævones, including all the others. Pliny (*Nat. Hist.*, iv. 14) makes five divisions: 1. Vindili, including Burgundiones, Varini, Carini, Guttones. 2. Ingævones, including Cimbri, Teutoni, and Chauci. 3. Istævones, near the Rhine, including the midland Cimbri. 4. Hermiones, inhabiting the central parts, including the Suevi, Hermunduri, Catti, and Cherusci. 5. Peucini and Bastarnæ, bordering on the Dacians.

The following list gives the position of the principal tribes as far as they can be ascertained: further particulars will be found in some separate articles, such as CATTI, CHAUCI, CIMBRI, &c.

1. *Tribes on the sea-coast.*—Between the Rhenus (Rhine) and the Amisia (Ems), the Frisii. Between the Amisia and the Albis (Elbe), the Chauci, divided into Chauci Minores and Chauci Majores. East of the Albis, the Cimbri, Saxones, and Angli. The peninsula of Jutland was also called Cimbrica Chersonesus. Farther east the Guttones and Teutones or Teutoni.

2. *Tribes on the right bank of the Rhine.*—Between the Frisii and the Luppia (Lippe), and bounded on the east by the Visurgis, the Bructeri, Tubantes, Chamavi, Marsi, Dulgibini, Angrivarii, Usipii or Usipetes. The Usipii, in conjunction with the Tencteri, made an irruption into Gaul in the time of Cæsar (Cæs., *Bel. Gal.*, iv., 1-15). Between the Luppia and Mœnus (Mayn), the Sigambri or Sicambri, Tencteri, and Mattiaci. South of the Mœnus, the Alemanni.

3. *Tribes on the left bank of the Danube.*—Between the Danube and the Erzgebirge and Riesengebirge, the Hermunduri, Narisci, Quadi, and Marcomanni, who dwelt in the districts formerly inhabited by the Boii.

4. *Tribes in the Central parts.*—The most powerful of

these were the Suevi, who occupied the greatest part of Germany, and were composed of several tribes. They extended from the Erzgebirge and Riesengebirge as far north as the Baltic, and included the Semnones, Langobardi, Aviones, Varini, Eudoses, Suardones, and Nuithones. South of the Chauci were the Cherusci and Chasuarii, and south of these the Catti. The Osi, Marsigni, Gothini, and Burii, probably inhabited part of Prussian Silesia. The Burgundiones and Lygii dwelt on the banks of the Vistula, bounded on the south by the Carpathian mountains, and on the west by the Riesengebirge.

History.—The origin of the Germanic nations, like that of all others, is uncertain. Some authors, taking as their guide the affinity of languages, have traced their descent from the inhabitants of Asia; and Von Hammer calls them a Bactriano-Median nation. But to assign to the Germanic nations a distinct historical origin is to make an assertion without evidence, though it is now indisputably established that the Teutonic dialects belong to one great family with the Latin, the Greek, the Sanscrit, and other European and Asiatic tongues. All the positive knowledge however that we have of the German nations previous to their contact with the Romans is exceedingly vague and mere conjecture. The Romans first became acquainted with them, B.C. 113, when they appeared under the name of Cimbri on the confines of the Roman dominion and defeated the consul Papirius Carbo. They made successive attacks on the frontiers, but were repelled by Marius, who defeated these barbarians in the years 103 and 101 B.C. When Julius Cæsar had subjugated Gallia and penetrated to the Rhine, he became acquainted with a nation then designated by the name of Germans. Ariovistus, the leader of the nation which had formerly inhabited the banks of the Danube, attempted to establish himself in Gallia; but being defeated by Cæsar, was obliged to fly beyond the Rhine. Cæsar twice crossed the Rhine in order to secure Gallia from the inroads of the barbarians: he took some Germans into his army, whom he employed against the Gauls, and afterwards against Pompey. He himself was only acquainted with the tribes of the Ubii, Sigambri, Usipetes, and Tencteri: he was told that the remaining part of Germany was inhabited by the Suevi, who possessed a hundred districts, every one of which yearly sent out one thousand men on predatory expeditions.

The civil wars which divided the Romans withdrew their attention for some time from Germany, and the Sigambri ravaged Gallia with impunity. After they had defeated Lollius, the legate of the Emperor Augustus (B.C. 15), he himself hastened to the defence of Gallia (Vell. Pat. ii. 97); and in order to oppose the inroads of the Germans, he erected several fortresses on the Rhine, and gave his stepson Drusus the command of the forces stationed on the banks of that river. Drusus made several successful expeditions against the Germanic nations, and penetrated as far as the Elbe. After the death of Drusus (B.C. 9), his brother Tiberius commanded for two years the legions stationed on the Rhine. Tiberius employed policy rather than force against the Germans. He engaged many of them to enter the Roman service; and when he was again (A.D. 4) entrusted with the same command, he penetrated as far as the banks of the Elbe; and Germany would have perhaps become a Roman province if the imprudence of his successor, Quintilius Varus, had not destroyed all the advantages already gained. The violent measures which he adopted to change the manners and institutions of the Germans caused a general conspiracy against the foreign invaders. Arminius, who was educated at Rome, and who had served in the Roman armies, was at the head of this conspiracy. The legions of Varus were attacked by the Germans in the forest of Teutoburg (A.D. 9), and entirely destroyed. This defeat of the Romans was followed by the loss of all their conquests beyond the Rhine; and the Germanic nation of the Cherusci, among whom Arminius was born, became the most powerful nation in Germany. Four years afterwards, Germanicus restored for a time the fortunes of the Roman arms, but without regaining the former acquisitions. From that time the Romans seem to have abandoned the idea of extending their conquests in that direction, and to have contented themselves with repelling the inroads which the Germans occasionally made on their frontiers. The Germans were also prevented from making any serious attempts against the Romans by the internal wars which distracted them for many years. They again attacked th Roman empire under Domitian, Nerva, and Trajan, the last of whom entirely defeated them. From this time their attacks on the Roman empire became more frequent and more formidable, and their history becomes blended with that of the decline of the Roman empire, on the ruins of which they established several new states. We shall pass over the period to the death of Charlemagne, under whose successors the modern history of Germany begins. Those who would study the state of Antient Germany may refer to the 'Germania' of Tacitus, and to the work of Mannert on Antient Germany, published in 1829, as well as to several other German works on the subject, but particularly those of Barth and Ledebuhr.

Modern History.—Louis, surnamed the Germanic, son of Louis Le Debonnair, and grandson of Charlemagne, was, by the treaty of Verdun, 843, the first king of the Germans. Germany was divided at that time from France by the Rhine, and possessed on its left bank only Spires, Worms, and Mainz, with their respective districts. These territories were given to the Germanic or Eastern Empire on account of their vineyards, in which the other parts of the empire were at that time deficient. Under the reign of Louis were established the margraves; and burgs, that is, fortified towns or castles, were founded in order to prevent the inroads of the Normans as well as of the Sclavonians. This emperor increased his dominions by the acquisition of Cologne, Treves, Aix-la-Chapelle, Utrecht, Metz, Strasburg, Basle, and many other towns and districts which he inherited from his nephew, Lotharius the Second. Louis died in 876, and his three sons, Carloman, Louis the Younger, and Charles the Fat, divided his empire. In 884 Germany was re-united to France by the accession of Charles the Fat to the throne of the last-named country, who thus became sovereign of almost all the empire possessed by his great predecessor Charlemagne. But he proved unequal to the difficult task of governing such extensive dominions, and sunk into such contempt with his subjects, that the Germans (in 887) renounced their allegiance to him, and raised to the throne his nephew, Arnulph of Carinthia, a natural son of his brother Carloman. Arnulph was for a long time involved in difficult wars with the Sclavonians of Moravia, against whom he called in the Hungarians, who had settled in their present country in 889: he was crowned emperor in 896, after a victory over Berengar, duke of Friuli. He died in 899, and was succeeded by his infant son Louis, who died in 911, and with whom the Carlovingian dynasty ended in Germany. Otho, duke of Saxony, having refused the imperial dignity on account of his great age, Conrad, the first duke of Franconia, was elected emperor of Germany. After Conrad's death (918), Henry the Fowler, duke of Saxony, was elected emperor. From that time the crown of Germany remained elective until the 6th of August, 1806, on which day the emperor Francis the Second abdicated the imperial crown of Germany, and declared the dissolution of the Germanic empire. Henry the Fowler died in 936, and the imperial dignity continued in his house under Otho I., who died in 973; Otho II., who died in 983; and Otho III., who died in 1002. The emperors of Germany assumed the title of Roman emperors from the time of Otho I., who was crowned at Rome in 962: when a successor to the throne was elected during the emperor's lifetime, he was called the king of Rome. Henry II. reigned from 1002 to 1024. Conrad the Second (1024-39) organized the feudal system, and first endeavoured to put an end to the factions and quarrels then universally prevalent, by the establishment of the so-called peace of God, Freuga Dei. He extended the limits of the empire by the incorporation of Burgundy. His successor, Henry the Third (1039-56), humbled the Roman see by deposing three successive popes, but the papal influence was again restored by Gregory the Seventh, who maintained a protracted struggle with the emperor Henry the Fourth (1056-1106).

The crusades began during the reign of this emperor, which was constantly disturbed by his quarrels with the Roman see, as well as with the powerful vassals of the German empire. Henry the Fifth (1106-25), son of the foregoing, was a prince without any talents, and of a bad character. Under his reign the great vassals of the empire became entirely independent, and thus the division of Germany into several states was established. He was followed by Lotharius the Second, or the Saxon count of Supplin-

burg (1125-37), who became emperor by making great concessions to the church.

The successor of Lotharius was Conrad III., duke of Franconia, of the family of Hohenstaufen (1138-52). He was constantly devoted to the Roman see and greatly increased the influence of the clergy. Conrad was succeeded by his nephew, Frederick I., or Barbarossa (1152-90), a prince of ability, whose reign is memorable for the establishment of the Hanseatic League. His life was spent in constant wars with the Italian republics and the Pope; and he died on his expedition to the Holy Land. Frederick Barbarossa was succeeded by his son Henri VI., who having married a princess of Naples, possessed himself of that kingdom as well as of Sicily, where he died in 1197. The peace of the empire was disturbed for some time by the competition between Philip, brother to the late emperor, and his nephew, Otho of Saxony. The dispute was settled by an arrangement that Philip should have the crown, and that Otho should succeed him. The former died in 1208, and the latter, who became emperor under the title of Otho IV., was driven from the throne by Frederic II., son of the emperor Henri VI., who was crowned in 1215. Frederic II. died in 1250: his reign, after that of Charlemagne, is perhaps the most remarkable period of the middle ages. His son, Conrad IV., was opposed by William of Holland, and died in 1254. Upon Conrad's death there were several competitors for the Imperial crown, among whom was Richard, earl of Cornwall, brother of Henry III. of England. The parties who supported the different competitors took advantage of the disturbed state of the empire in order to strengthen their own power. Peace was restored by the accession of Rudolph I., count of Habsburg (1272-91). This great prince destroyed the strongholds of the nobles, who exercised constant depredations on the adjacent country, and established order by severe measures. Rudolph is the founder of the Habsburg dynasty, which through a female line still reigns in Austria. After his death, Adolphus, duke of Nassau, was elected emperor. He was killed in battle in 1298, and Rudolph's son, Albert I. of Austria, ascended the throne. Albert's reign (1298-1308) is rendered remarkable by the emancipation of the Swiss from Austr a. Albert was succeeded by Henry VII. of Luxembourg, whose reign was spent in constant wars in Italy, which at that time was divided between the Guelph and the Ghibeline parties.

After Henry's death Louis of Bavaria was elected emperor; his reign (1314-47) was marked by frequent wars in Italy. He was succeeded by Charles IV. of Luxembourg, king of Bohemia, whose reign (1346-78) is particularly remarkable by the constitution of the empire which he proclaimed (in 1356) under the name of the Golden Bull. This constitution regulated the rights, privileges, and duties of the electors; the manner and formalities of the election and coronation of an emperor; the coinage, customs, and other articles relating to the commerce of the empire; the rights and obligations of the free imperial cities, &c. Charles's son, Wenceslaus (1378-1410), was a weak prince whose reign was disturbed by internal commotions and distinguished by the commencement of Huss's reformation. After the death of Wenceslaus, his brother Sigismund ascended the throne (1411-37). During his reign the council of Constance was held, when Huss was executed, a transaction which gave rise to the wars of the Hussites. Sigismund was succeeded by Albert II. of Austria (1437-39), whose short reign presents no particular event.

The long reign of Albert's successor, Frederick III. (1439-93), a weak-minded prince, was marked by the great progress of science, which was promoted by the foundation of many universities in Germany. Frederick's son, Maximilian I. (1493-1519), was a prince of a superior mind and character. He put an end to many abuses which had desolated the empire, particularly private feuds. He improved the organization of the courts of justice, introduced a system of police for the better security of the inhabitants, and established (in 1516) the post. He gave also a new and better organization to the army, being himself an accomplished military commander. It was also during his reign that the reformation of Luther began (1517), at the university of Wittemberg, which had been founded in 1502.

Maximilian was succeeded by his grandson, Charles V., king of Spain. After the abdication of Charles in 1556, he was succeeded by his brother, Ferdinand I., who was of a conciliatory character, and granted entire toleration to the Protestants. Ferdinand's son and successor, Maximilian II., reigned from 1564 to 1576; and his son Rudolph II., from 1576 to 1612. Rudolph was a weak-minded prince, who neglected the duties of his exalted station, and occupied himself with chemistry, astrology, and mechanics. Although a zealous Roman Catholic, he was obliged to grant to his hereditary Bohemian subjects the full enjoyment of religious liberty. Under his successor Matthias (1612-19), the Thirty Years' War commenced in 1618. Matthias was followed by Ferdinand II. (1619-37), a bigotted Roman Catholic, whose fanatical zeal against the Protestants, as well as his political ambition, continued to involve Germany in the Thirty Years' War. Ferdinand III., son of the preceding, reigned from 1637 to 1657. The treaty of Westphalia, which terminated the war in 1648, established a new organization of the German empire. By this treaty, which served as the basis of the constitution of Germany till the formation of the Confederation of the Rhine in 1806, the religious and political liberties of the Germans were established on a sure footing. The sovereignty of the states of the empire was acknowledged, as well as their right to form alliances among themselves and with foreign states, provided none were concluded against the emperor or the empire. It was also declared that the emperor should not, without the consent of the states, put any one of them under the ban of the empire. The Palatine of the Rhine, who had lost his states, recovered them by that treaty and was created an elector. The Protestants were confirmed in all the liberties which they possessed before the war, and the estates of the Roman Catholic church, which had been seized by the Protestants and possessed by them in 1624, were left in their hands, but those seized after this time were restored to the Roman Catholics. The members of the Reformed Church received equal rights with the Lutherans. Several bishoprics and abbeys were secularized, and given as an indemnity to different states. All the sovereigns were put under an obligation not to persecute their subjects who professed a religion different from their own. Alsatia was ceded to France; Sweden received a part of Pomerania, Bremen, Verden, Wismar, and a sum of five million dollars for its army; Brandenburg received the secularized bishoprics of Halberstadt, Minden, Kamin, and the expectation of the possession of Magdeburg; Mecklenburg, the secularized bishoprics of Schwerin and Ratzeburg. Hanover was invested with the right to have one of its princes created, alternately with a Roman Catholic, sovereign bishop of Osnabrück, and also received some convents with their estates. The abbey of Hirschfeldt and 600,000 dollars were given to Hessen Cassel. Austria consented to all these measures in order to preserve her hereditary states. Holland was acknowledged by Spain as an independent state. France and Sweden declared themselves guarantees of all the provisions of the abovementioned treaty. Leopold I. (1657-1705), was involved in constant wars with France and with the Turks, who besieged his capital, Vienna, which was saved by John Sobieski, king of Poland. Leopold granted in 1692 the electoral dignity to the duke of Brunswick-Lüneburg, and conferred in 1701 the royal crown on the elector of Brandenburg, who took from that time the title of king of Prussia.

The whole reign of Leopold's son and successor, Joseph I. (1705-11), was occupied in the war of the Spanish succession. He was succeeded by his brother Charles VI. (1711-40), with whose death the male line of the Habsburg dynasty became extinct, and his only daughter, Maria Theresa, succeeded to the throne of the hereditary states of Austria.

The elector of Bavaria, who was elected emperor in 1742, put forward claims to the succession of the Austrian states, and other sovereigns took advantage of that circumstance to attack Maria Theresa, who was married to the duke of Lorraine. A war ensued, which was ended by the peace of Aix-la-Chapelle in 1748; but the emperor Charles VII. having died in 1745, the husband of Maria Theresa was elected emperor under the name of Francis I. In his reign the Seven Years' War was concluded by the treaty of Hubertsburg in 1763. Francis was succeeded in 1765 by his son Joseph II., who distinguished himself by the numerous reforms which he introduced into his dominions, and particularly by his act of toleration to all the religious persuasions, proclaimed in 1781. Joseph was succeeded, 1790, by his brother, Leopold II., who had been duke of Tuscany before his accession to the imperial throne. The short reign of Leopold is marked by the treaty of Pilnitz, which he concluded

in 1791 with the king of Prussia against the French. Leopold was succeeded in 1792 by his son, the late emperor Francis, who, after the formation of the Rhenish Confederation, having resigned the title of Emperor of Germany, took that of Emperor of Austria. The Confederation of the Rhine was established by an act, signed at Paris on the 12th of July, 1806, by the kings of Bavaria and Wirtemberg, the elector of Mainz, the elector of Baden, the duke of Cleves and Berg (Murat), the landgrave of Hesse-Darmstadt, the princes of Nassau-Usingen, Nassau-Weilburg, Hohenzollern-Hechingen, Hohenzollern-Siegmaringen, Salm-Salm, Salm-Kyrburg; the duke of Aremberg; the princes of Isenburg, Birstein, Lichtenstein, and the count of Leyen. By this act the elector of Mainz received the title of the Prince Primate; the elector of Baden, the landgrave of Hesse-Darmstadt, and the duke of Berg, received the titles of grand-dukes, with royal rights and privileges; the prince of Nassau-Usingen received the ducal, and the count of Leyen the princely dignity. The French emperor declared himself Protector of the Confederation. By the establishment of this confederation many towns and principalities lost their political existence: such were the imperial city of Nürnberg, which was given to Bavaria; and Frankfort, which was given to the prince primate. Several petty sovereign princes were by the same act mediatised, or deprived of their sovereign rights, such as making laws, concluding alliances, declaring war, coining money, &c.: they retained their hereditary estates, but became subjects to the sovereigns who were members of the Confederation. The object of the Confederation was declared to be, the maintenance of external and internal peace by the mutual assistance of all the members of the Confederation as well as of France, in case any one of them should be attacked by an enemy. The affairs of the Confederation were to be conducted by a congress sitting at Frankfort on the Main, and divided into two colleges—the royal one, in which the grand-dukes had also their seats, and the princely one. The president of the congress in general, and of the royal college in particular, was the Prince Primate, but the president of the princely college was the duke of Nassau. The elector of Würzburg joined the Confederation in the same year, and the king of Prussia meditated the establishment under his own protection, of a similar Confederation, composed of the princes of Northern Germany, in order to counterbalance the power of the Confederation of the Rhine. This project was destroyed by the war of 1806, which was not over when the elector of Saxony, who had received the title of king, by his treaty with France, on the 11th of December, 1806, joined the Confederation, and his example was followed by all the Saxon princes. By the treaty of Warsaw, on the 13th April, 1807, the two princes of Schwarzburg, the three ducal lines of Anhalt, the princes of Lippe Dettmold and of Lippe Schaumburg, and the princes of Reuss, were received members of the Confederation, which was increased by the accession of the newly-erected kingdom of Westphalia, as well as that of both the dukes of Mecklenburg, and of the duke of Oldenburg. Thus in 1808 the Confederation comprehended 5916 geographical square (German) miles, with a population of 14,608,877 souls; the army of the Confederation, which was fixed in the beginning at 63,000, was increased to the number of 119,180. The act of the Confederation was violated by its protector himself, who united with France, by a decree of the 10th December, 1810, all the country situated between the mouths of the Schelde and the Elbe, and deprived many sovereign princes of their dominions, taking away from the Confederation of the Rhine an extent of 532 geographical square (German) miles, with a population of 1,133,057. Napoleon did not observe any better the promise which he gave at the establishment of the Confederation not to meddle with its internal affairs, but treated it in every respect as one of his provinces. The events of 1813 put an end to the Confederation of the Rhine; and the Congress of Vienna established, in 1815, the Germanic Confederation, composed of all the states of Germany. The present Germanic Confederation, established by an act of the Congress of Vienna on the 8th June, 1815, consists of thirty-eight Independent States enumerated in the Statistical Tables of EUROPE.* The central point and the organ of the Confederation is the Federative diet, which sits at Frankfort on the Main. Its sessions were opened on the 5th of November, 1816. It exercises its authority in a double form: 1, as a general assembly, called Plenum; and 2, as a minor council, or the Federative government. The Plenum meets only whenever an organic change is to be introduced, or any affair relating to all the Confederation is to be decided. The Plenum contains seventy votes, of which Austria and the eight German kingdoms have each four votes, and the other states, in proportion to their importance, three, two, or one vote each. The Federative government is composed of seventeen votes, out of which eleven principal states have each a single vote, and the remaining twenty-seven only six joint votes. Austria presides in both the assemblies, and decides in case of equality. The Federative government has the initiative, and deliberates on the projects which are presented to the Plenum, where they are not debated, but simply decided by a majority of ayes or noes. It executes the enactments of the Plenum, and despatches the current business of the Confederation. It decides by a simple majority, and seven votes form a quorum. The meetings of the Federative diet are either those wherein preparatory debates take place, but no protocols are made, or those wherein affairs are finally decided.

The object of the Germanic Confederation and the duties of the Federative diet are—the maintenance of external security or mutual defence from a common enemy, and the preservation of internal peace among the Federative states, which have no right to declare war on each other, but must submit their differences to the decision of the diet. The maintenance of internal security comprehends not only the prevention of conflicts among the Federative states, but also the suppression of any attempt by the subjects of any of the states to subvert the existing order of things. It was in consequence of this principle that the central commission of inquiry into revolutionary measures was established at Mainz in 1819-28. A further development of the same principle, occasioned by the revival of liberal opinions throughout Germany by the French Revolution of July, was made on the 28th June, 1832, by the proclamation of the following articles, particularly directed against the constitutional states of Germany:—1st. The German sovereigns are not only authorised but even obliged to reject all propositions of the states which are contrary to the fundamental principle, that all sovereign power emanates from the monarch, and that he is limited by the assent of the states only in the exercise of certain rights. 2. The stoppage of supplies by the states, in order to obtain the adoption of their propositions, is to be considered as sedition against which the Confederation may act. 3. The legislation of the federative states must never be in contradiction either to the object of the Federation or to the fulfilment of federal duties; and such laws (as for instance, the law of Baden, which established the liberty of the press) may be abolished by the diet. 4. A permanent commission of federal deputies shall watch over the legislative assemblies of the federal states, in order that nothing contrary to the federal act may occur. 5. The deputies of the legislative assemblies of the federal states must be kept by the regulations of their governments within such limits that the public peace shall not be disturbed by any attacks upon the Confederation. 6. The interpretation of the federal laws belongs exclusively to the federal diet. On the 5th July, 1833, the federal diet proclaimed a new law consisting of the following 10 articles: 1. All German works containing less than 20 sheets which appear in foreign countries cannot be circulated in the federal states without the authorization of the several governments. 2. Every association having a political object is prohibited. 3. Political meetings and public solemnities, except such as have been established for a long time and are authorized, cannot be held without the permission of the several governments. 4. All sorts of colours, badges, &c. denoting a party are proscribed. 5. The regulations for the surveillance of the universities, proclaimed in 1819, are renewed and rendered more severe. By the remaining 5 articles the federative states pledged themselves to exercise a vigilant watch over their respective subjects, as well as over foreigners residing in their states, in respect of revolutionary attempts; to surrender mutually all those individuals who had been guilty of political offences, with the exception of their own subjects, who are to be punished in their own country; to give mutually military assistance, in case of disturbance, and to notify to the diet all measures adopted with reference to the above-mentioned objects.

* To those marked with an asterisk in EUROPE (vol. x., p. 89) as sovereign states must be added, Frankfort on the Main, Holstein and Lauenburg, and Luxemburg. Schwarzburg and Reuss are each to be reckoned as two.

On the 30th October, 1834, the meeting of the Federative diet unanimously agreed to the proposition of Austria, to establish a tribunal of arbitration in order to decide differences which might break out in any state of the Confederation between the government and the chambers respecting the interpretation of the constitution, or the encroachments on the rights of the sovereign by the chambers, or their refusal of subsidies. This tribunal consists of 34 arbitrators nominated by the seventeen members of the minor council, each member nominating two arbitrators.

Constitution of the German Empire as it was before the French Revolution.—The states of the Germanic empire consisted of the following members, divided into three colleges, or chambers:—

I. The Electoral College, which consisted of the Ecclesiastical Electors.

1. The archbishop of Mainz, arch-chancellor of the empire for Germany.

2. Archbishop of Treves, arch-chancellor of the empire for Gallia and the kingdom of Arles (a purely titular office).

3. Archbishop of Cologne, arch-chancellor for Italy (also a titular office).

II. The Secular Electors were—

4. The king of Bohemia, arch-cupbearer of the empire: he presented the emperor at the coronation banquet with a cup of wine and water.

5. The elector of Bavaria, arch-carver of the empire: he bore at the coronation-procession the golden bull before the emperor, and presented to him the dishes at the banquet.

6. The elector of Saxony, arch-marshal of the empire: he bore in the great solemnities of the empire the sword of state, and at the coronation preceded the emperor on horseback.

7. The elector of Brandenburg, arch-chamberlain of the empire: he bore in the coronation-procession the sceptre, and presented to the emperor a basin with water to wash his hands.

8. The elector palatine of the Rhine had the title of the arch-treasurer of the empire: his duties were to scatter at the coronation gold and silver medals, struck for the occasion, amongst the people. This electorate became united with that of Bavaria by the accession of the elector to the throne of the last-named principality in 1777, after the extinction of the reigning house of Bavaria.

9. The elector of Brunswick-Lüneburg, or Hanover, created by the Emperor Leopold I. in 1692, received in 1706 the title of arch-treasurer; when the emperor, having put to the ban of the empire the elector of Bavaria, took from him the office of the arch-carver, and bestowed it on the elector palatine of the Rhine, whose office on that occasion was given to Hanover.

The Second College consisted of the princes of the empire, who were in rank next to the electors: they had each a vote in the diet of the empire, and were divided into Spiritual and Temporal princes.

The Spiritual princes of the empire who had a vote in the diet were:—the archbishop of Salzburg, and formerly the archbishop of Besançon; the grand-master of the German order; the bishops of Bamberg, Würzburg, Worms, Eichstaedt, Spires, Strasburg, Constance, Augsburg, Hildesheim, Paderborn, Freysingen, Passau, Ratisbon, Trent, Brixen, Basil, Münster, Osnabrück, Liege, Chur, Fulda, Lubeck; the princely (gefürstete) abbot of Kempten; the princely prebendaries of Berchtolsgaden and Weissenburg; the princely abbots of Prüm, Stablo, and Corvey.

The Temporal princes were:—the archduke of Austria; the dukes of Burgundy, Magdeburg; the counts palatine of Lautern, Simmern, and Neuburg; of Deuxponts (Zweibrücken), of Veldenz, and Lautereken; the dukes of Bremen, of Saxen-Weymar, Eisenach-Gotha, Altenburg, Coburg; the margraves of Brandenburg-Culmbach, and of Brandenburg-Onolzbach; the dukes of Brunswick, Zell, Grubenhagen, Calenberg, and Wolfenbüttel; the prince of Halberstadt; the dukes of Upper and Lower Pomerania; of Verden, Mecklenburg-Schwerin, Mecklenburg-Gustrow (afterwards Strelitz); of Wirtemberg; the landgraves of Hessen-Cassel and Hessen-Darmstadt; the margraves of Baden-Baden, Baden-Durlach, and Baden-Hochberg; the dukes of Holstein, Gottorp, of Saxe-Lauenburg; the prince of Minden; the landgrave of Leuchtenberg; the prince of Anhalt; the princely count of Henneberg; the princes of Schwerin, Kamin, Ratzeburg, and Hersfeldt; the princely count of Montbeliard. The princes enumerated belonged to the old body; the following, who were elevated to their dignities after the time of the Emperor Ferdinand II., were called the new:—the duke of Aremberg; the princes of Hohenzollern, Salm, Lobkowitz, Dietrichstein, Nassau-Hadamar, Nassau-Dillenburg, Auersberg, East Friesland, Schwarzenberg, Lichtenstein, Thurn-Taxis, and Schwarzburg. Many of these principalities were in the possession of one individual, who had consequently several votes, the votes being attached to the states and not to individuals.

The prelates, abbots, and abbesses of the empire were divided into two benches, the Suabian and the Rhenish, of which each had one vote. The counts and nobles of the empire were divided into four benches; of Suabia, Franconia, Westphalia, and of Wetterau, each having one vote. They belonged to the second college.

The free Imperial cities formed a college at the diet, divided into two benches, the Rhenish with fourteen cities, and the Suabian with thirty-seven. Each town had a vote.

The above-mentioned three colleges formed the diet of the empire, whose ordinary meetings were formerly summoned by the emperors twice a-year, in addition to extraordinary meetings. But from the year 1663 the diet sat at Ratisbon. The emperor at first appeared personally at the diet, but in course of time he sent a delegate, called Principal Commissiarius, who was always himself a prince of the empire, and who had an assistant, called Con-commissiarius. The elector of Mainz, as arch-chancellor for Germany, or his deputy, presided in the diet, and every despatch addressed to the diet was directed to him, and communicated from his chancery to the members of the diet. The president of the first college was the elector of Mainz; of the second, alternately, the archbishop of Salzburg and the arch-duke of Austria; and of the third, the representative of the town where the diet was held. Every college voted separately; and when their respective decisions on the subject under discussion agreed, the matter was presented for the ratification of the emperor; after which it became law, and was called *conclusum imperii*. The emperor could refuse his ratification, but could not modify the decisions of the diet.

The diet had the right of enacting, abolishing, and interpreting laws; of declaring war; concluding peace; contracting alliances; receiving foreign ambassadors, &c. A declaration of war was decided, on an Imperial proposition, by a majority of votes; and when it was decided, even those states that had voted against it were obliged to furnish their contingents. The diet also imposed taxes for the eneral expenses of the empire.

There were two tribunals for the decision of points in dispute between the members of the empire; the Aulic council of the empire, which had its seat always at the residence of the emperor; and the Cameral tribunal of the empire (Cameralgericht), which sat at Wetzlar. They were composed of members delegated by the different states of the empire, and an imperial deputy presided.

The emperor was elected only by the electors, who could do it either personally or by deputies. The place of election was Frankfort on the Main, where the coronation also took place, although the golden bull of Charles IV. declared that the emperor should be elected at Frankfort, but crowned at Aix-la-Chapelle. All strangers, even the princes of the empire and foreign ambassadors, were obliged to leave the town on the day of the election, which took place in a chapel of St. Bartholomew's Church. Mainz was the teller; and after having collected the votes, gave his own to Saxony. The emperor, immediately after the election, swore to the constitution, or, as it was legally termed, capitulation. He could do it either personally or by deputy.

The immediate nobility of the empire, who acknowledge no other sovereign than the emperor himself, and who, as we have mentioned, had their collective votes in the diets, were also judged by the two above-mentioned courts of justice.

German Language and Literature.—The German or Teutonic language may be divided into two great branches, which are subdivided into several dialects: the High German, or the language of Southern Germany; and the Low German, or Saxon, which is used in the northern part of that country.

The High German was formerly divided into two dia-

lects, the Francic and the Allemannic. The Francic was the idiom of the Franks and that of the French court till the reign of Charles the Bald, when it was replaced by the French. The principal monuments of this dialect are, the fragments of a treatise of Isidore, *De Nativitate Christi*, which date from the beginning of the eighth century, and some fragments of the poem of Hildebrand and Hadubrand, which belong to the end of the same century, as well as the oath of Charles the Bald. [FRENCH LITERATURE.] It was used at the court of the German emperors till the accession of the Hohenstauffen. The Allemannic dialect prevailed in the south-western part of Germany, including a great part of Switzerland. Its most antient monuments are—a translation of the rules of St. Benedict, made about the beginning of the eighth century; the poetical paraphrase of the gospels by Ottfried, and a translation of Psalms by a monk called Noker, made about the beginning of the tenth century. Both the abovementioned dialects seem to have disappeared in the middle ages and to have been replaced by the Suabian dialect, which became the language of the court under the Hohenstauffen dynasty, and in which the Minnesingers composed their poems.

The modern German, also called High German (Hoch Deutsch), may be considered as chiefly derived from the old High German, or southern dialect. Its universal usage as the literary language of all Germany dates from Luther's translation of the Bible, by which circumstance it acquired a decided superiority over all the dialects of Germany.

The written language of modern Germany must however be distinguished from that which is only spoken. The spoken language may be divided into the following dialects: 1, the Swiss, which is spoken in German Switzerland, and which itself may be subdivided into several dialects· as for instance, that of Berne and Argau; that of the valley of Hasli; of Freiburg; of the Grisons; and of Appenzel; 2, the Rhenish dialect, which is likewise subdivided into many dialects, as that of Alsatia, of Suabia, &c.; 3, the Danubian, subdivided into the Bavarian, Austrian, and Tyrolese dialects.

The Saxon, that is, the language of Northern or Lower Germany, may be divided into the following dialects: 1, the old Low German (Alt Nieder Deutsch), called also the old Saxon, from the nation that spoke it. This language, which is now entirely extinct, was spoken at an early period, and during a part of the middle ages in all the north of Germany as well as in the Low Countries, except the parts inhabited by the Frisians and the Angles. The works written in this language were composed from the eighth to the eleventh century: the principal of them is the *Evangelien Harmony*, which seems to date from the beginning of the ninth century; 2, the Low German of the middle ages, which was in use from the eleventh to the sixteenth century, contains many works, but its literature is very inferior to that of the Suabian, or the High German of the middle ages. The chief productions in that dialect are: a Vocabulary composed in the twelfth century; a translation of the Bible, made at the beginning of the thirteenth; and the well known comic productions 'Reineke der Fuchs' and 'Til Eulenspiegel; 3, the modern Low German, which is spoken over almost all Northern Germany, but has ceased to be a written language. Its literature is very poor, and contains, besides popular songs, only some grammars, vocabularies, and a few chronicles, of which the principal is that of Livonia by Russow. This language, which is subdivided into many dialects, is distinguished by the softness of its sounds, and has fewer gutturals and accumulated hissing consonants than the High German dialects. It is poorer in grammatical forms than the above-mentioned dialects, but it contains more roots. The Low German is divided into three principal dialects: 1, the Saxon proper, or the idiom of Lower Saxony, which is subdivided into the dialects of Hamburg, Holstein, Schleswig, Hanover, &c.; 2, the Oriental Saxon, which is also subdivided into the idioms of Higher Saxony, Brandenburg, Pomerania; 3, the Occidental Saxon, or Westphalian, which is also subdivided into several dialects.

The Frisian language is a branch of the German tongue. It may be divided into three dialects: 1, the Batavo-Frisian, which very much resembles the Anglo-Saxon, and which was formerly spoken in many parts of the north of Holland, but is now preserved only in a few places about the towns of Moleweren and Hindelopen in West Friesland; 2, the Westphalian Frisian, which was spoken in many parts of Westphalia, but is now entirely extinct and replaced by the Saxon; 3, the Northern Frisian, which still exists on the island of Heligoland as well as in some parts of Schleswig, where Frisian settlers established themselves in the middle ages. The Frisian literature is very poor.

The Anglo-Saxon language is treated in a separate article. [SAXON LANGUAGE.] The Dutch and Flemish are spoken of in the article NETHERLANDS. The Scandinavian languages are also a branch of the German tongue.

Those who wish to study the history of the Teutonic languages will find ample information in the learned works of the two brothers Grimm, which have been republished several times in Germany.

The most antient monument of German literature extant is the translation of the Bible into the Gothic language by Bishop Ulfilas. It was made in the second part of the fourth century, for the use of the Gothic tribe of the Thervingians, who, having settled on the banks of the Danube, in the antient Roman province of Mœsia, were generally called Mœso-Goths. Ulfilas on that occasion introduced a new alphabet by modifying the old Runic characters, which were in general use amongst the Teutonic nations. The library of Upsal in Sweden possesses a remarkable fragment of this translation, well known under the name of the *Codex Argenteus*, being written in silver letters on a purple-coloured parchment. It contains the four gospels, and is supposed to have been written in the fifth or at least in the beginning of the sixth century, among the Goths of Italy. Some fragments of St. Paul's epistles to the Romans were discovered on a palimpsest in the library of Wolfenbüttel; and several parts of the books of Esdras and Nehemiah, as well as several epistles of St. Paul, preserved in the same manner, were discovered in the library of Milan by Angelo Mai. Several editions of those fragments, accompanied by interesting commentaries, have been lately published in Germany.

First period: from Charlemagne to the Accession of the Suabian dynasty.—The reign of Charlemagne may be considered as the commencement of the German literature, although there are some fragments of translations from ecclesiastical books which were probably made prior to that epoch. Charlemagne, who was very anxious to promote the cultivation of his native language, introduced German names of months. He ordered the scattered monuments of the Teutonic language, particularly laws or customs, and songs, to be collected. He also ordered the ministers of religion to preach in German, and directed the translation of several things from the Latin for the information of the common people. He also wished to have a German grammar made, but this important object seems not to have been effected at that time. It is impossible to know whether the songs collected by the order of Charlemagne were of the same kind as those which, according to the description of Tacitus, were in use amongst the Germans about the beginning of our æra, or to form any correct idea of them, as the collection is entirely lost. The two most antient German poems are, the 'Lay of Hildebrand and Hadubrand,' and the 'Prayer of Weiszenbrun,' which have been published by Grimm, and which belong to the eighth century.

After the reign of Charlemagne, the Christian religion being established throughout all Germany, many fragments of the Bible and some ecclesiastical writings were paraphrased from the Latin into the vulgar tongue. The separation of the Germanic empire from the French, which took place in the middle of the ninth century, acted beneficially on the national language and literature. The earliest known German poem of that time is a song written in commemoration of the victory which Louis III. of France gained over the Normans in 881. Another curious monument of the literature of that time is the laudatory poem on Saint Anno, archbishop of Cologne and tutor of the Emperor Henry IV. But the most remarkable production is the metrical paraphrase of the gospels by Ottfried, a Benedictine monk, made about 870, which shows an uncommon poetical genius in the author, who had to contend with all the difficulties presented by a rude and uncultivated language. To this period belong also the chroniclers Wittikind, Dithmar, Lambert, and Bruno, who all wrote in Latin.

Second period: from the Accession of the Suabian Dynasty to the Reformation of Luther, 1137-1517.—The reign of the emperors of the Suabian family of Hohenstauffen is the golden age of the romantic or chivalrous poetry of Ger

many. This poetry being written in the Suabian dialect, which came into fashion through the influence of the reigning family, is generally called the Suabian. Germany at that time had made great progress in civilization, particularly by its frequent intercourse with Italy, which was owing to the expeditions of the emperors to that country. This circumstance led to an acquaintance with the Troubadours of Provence; and the Crusades also, which brought the Germans into contact with more civilized nations, such as the Greeks and the Saracens, powerfully contributed to advance the intellectual development of the nation, and to exalt their chivalrous spirit. The poets of that period are known under the name of Minnesingers, from the old German word *minne*, which signifies 'love.' They may be compared in many respects with the Troubadours of Provence, and were generally knights and nobles, whose life was divided between the occupations of love, war, and devotion, which inspired their poetical effusions with tender, noble, and pious feelings. They lived chiefly at the courts of German princes, who were fond of poetry, and many of whom were poets themselves. Such were, among others, the Emperor Frederick II., Leopold IV., duke of Austria, Henry margrave of Misnia, Herman margrave of Thuringia, &c. The court life, which was spent amidst tournaments and splendid entertainments of every kind, gave to their poetry a high degree of refinement and brilliancy. Love and the praise of ladies were the principal themes of their compositions, in which however were intermingled the description of chivalrous exploits generally performed either in defence of religion or for the honour of the fair. Most of these poems are original and written on national subjects. There are many however which are imitations from the Troubadours. The versification of these poems is exceedingly varied, and they were generally set to music and sung by their authors. The most antient Minnesinger whose works have reached us is Henry Von Veldek; next to him the most celebrated are Walter von der Vogelweyde, Reimar the Old, Reimar von Zweter, Ulrich von Lichtenstein, Wolfram von Eshenbach, Hartman von der Aue, and some others, who all lived either at the end of the twelfth or at the beginning of the thirteenth century. The last of these poets who deserve notice are John of Würzberg and John Hadloup, who both lived at the end of the thirteenth century.

The best and most complete collection of the small poems of this period, which contains between 1400 and 1500 songs, the labour of 140 poets, was made in the fourteenth century by Rüdiger Von Manesse, Burgomaster of Zürich, and published by Bodmer and Breitinger, in ten volumes quarto, 1758-59, at Zürich.

The most remarkable production of that time is the celebrated 'Nibelungen Lied,' which is quite different from the poems of the Minnesingers, and whose origin is by many ascribed to a much more remote period. It is a kind of epic poem, of which the chief heroes are Attila, or Etzel, king of the Huns, and Dietrich, or Thedoric, of Berne, king of the Goths. There are several minor poems of the same kind and on similar subjects, which were collected and published for the first time in 1490, under the title of 'Heldenbuch,' or heroic book. This collection has been reprinted several times in the old language, and also translated into modern German. The decline of chivalry put an end to the Minnesingers, and the art of poetry descended from the nobles to the burgers of cities; welfare and civilization being secured by their fortified towns, gave them a decided advantage over the nobles, who abandoned themselves to the greatest excesses, and lived in a most lawless state, being constantly engaged in mutual feuds and depredations during the troubles which agitated the German empire in the latter part of the 13th century, after the death of Frederic II.

The cultivation of poetry by the burgers became a kind of trade, and the poets, who formed a corporation like other artisans and tradesmen, were called Meistersingers, or master singers. They had their rules like other corporations, and the members were obliged to submit to an apprenticeship. Their poetry was of a different kind from that of the Minnesingers. The exploits of chivalry and the enthusiastic love or rather worship of ladies were no longer the exclusive themes of their compositions, although they produced some metrical chronicles. The general subjects of the poems of this period are of a moral and satirical character, but there are also some of the didactic kind. The most celebrated productions of this school are the well-known poems, 'Reinecke Der Fuchs,' translated into English, and published for the first time under the following title:—'The History of Reynart the Foxe, by me William Caxton, translated from the Dutch into English, in Thabbey of Westmestre,' 1481, folio, which has been frequently reprinted; and the 'Narrenschiff,' which has also been translated (not from the German original, but from a Latin translation, entitled 'Stultifera Navis') into English under the title of the 'Shippe of Fooles,' by Alexander Barclay.

There are many other productions of a similar kind, all characterized by an overflowing comic and satirical humour. The best specimen of this national humour is the celebrated production called 'Eulenspiegel,' translated into English under the title of 'Owleglass,' London, 1709.

To this epoch belongs the commencement of the original dramatic literature of Germany, which is due to the meistersingers' school of Nürnberg. Before that period the Germans were only acquainted with the so-called mysteries or dramatized biblical stories, written and performed for the most part in Latin. About the middle of the 15th century, Hans Volz, a barber by profession, Rosenblut, and some others, introduced a kind of farce called 'Carnival Plays.' They were all excelled by Hans Sachs, a shoemaker by profession, who lived from 1494 to 1576: his works are full of wit and, invention, and next, to the Spaniard Lope de Vega, he is the most fertile of dramatic writers.

Many historical and allegorical poems were written during the 15th century, and several ballads and other metrical productions were rendered into prose, which may be considered as the commencement of the novel in Germany. Amongst the historical works which belong to this period we may mention the chronicles of Bishop Otho, of Freisingen, and his 'History of Frederick I.'; the works of Henry of Erfurt, who died in 1370; those of Gobelinus, who died about 1420; and some others, all written in Latin. The 'Fürstenbuch, or Book of Princes,' by John Enenkel, 1250; the 'Metrical Chronicle' of Ottokor, of Horneck, born about 1264; the 'Chronicles' of James Von Koenigshofen, of John Rothe, of John Thurmayr (Aventinus); the 'Pomeranian Chronicle,' by Kantzow, and that of Lubeck, by Detmar, were written in German. The 'Chronicle of the World,' by Sebastian Frank, is the first universal history in the German language. Among the scholastic philosophers several Germans distinguished themselves from the beginning of the 13th century; we may quote as one of the most celebrated Albert Grosz, or Grot, better known under the name of Albertus Magnus, who distinguished himself also by a knowledge of natural philosophy superior to that of his contemporaries, and who in many respects may be compared with Roger Bacon. Many collections of laws were also made during this period, of which the most celebrated are the *Sachsenspiegel* and the *Schwabenspiegel*, *i. e.* the Saxon and the Swabian Mirror, both compiled in the 13th century. The invention of the art of printing, of which the Germans are so justly proud, gave a new impulse to literature and prepared the way for the Reformation. We conclude the brief sketch of this period with the names of the following authors who belong to it:—Rudolph Agricola, 1443-85, professor at the university of Heidelberg; and Conrad Celtes, 1459-1508. Reuchlin, Ulaic Von Hutten, and Camerarius, form a link between this and the following period.

Third period: from the beginning of the Reformation, 1517, to the present day.—The Reformation of Luther gave an extraordinary impulse to the national literature of Germany, and Luther himself contributed more than any other man to the advancement of the German language, which may be considered as having been fixed by his translation of the Scriptures. The religious quarrels which agitated Germany during the sixteenth century gave to literature a theological direction, and the first scholars of that time were more or less engaged in religious controversy. Among the poets we may mention Luther himself, who composed many religious songs; Rudolph, Weckherlin, and, above all, Opitz, the founder of the so-called Silesian school.

Opitz (1597—1639) greatly improved the style of German poetry by imitating the classics. The German language is indebted to him for more correctness and harmony, but particularly for having purified it from the barbarisms with which it had been loaded. Among the principal followers of Opitz, who form the Silesian school, we may mention — Paul Flemming, 1609—40; Simeon Dach, 1605—59; A. Tcherning, 1611—59; Paul Gerhard,

1606—76; F. Van Logau, 1604—55; A. Gryphius, 1616—64; and John Rist, 1607—61. Many literary societies, whose object was to promote the national literature, were formed in the seventeenth century; the most remarkable were the Order of Flowers, established in 1044, and the Fructifying Society, established in 1617, by Louis, prince of Anhalt.

The German poetry of the seventeenth century is however very deficient in real merit, and except some religious songs there is scarcely any poetical production which can be read at present. The general characteristics of the poetry of this period are ridiculous bombast and affected mannerism introduced by some imitators of the Italian poetry of Marino's school.

Among the prose writers we must mention in the first place the mystical authors, or the so-called theosophists, who united the study of divinity and metaphysics with that of natural philosophy. The most celebrated are Paracelsus, well known as a physician and chemist; and Weigel, a Saxon clergyman, who may be considered as the pupil of Paracelsus, having imbibed his doctrines from the works of his master, and adapted them to divinity and ethics. To the same school belongs Jacob Boehme.

The best historical works of this period are the Magdeburg 'Centuriæ,' an ecclesiastical history written in Latin, in order to prove the concordance of the Protestant doctrines with those of the primitive church. It derives its title from being divided into centuries, of which one is contained in each volume. Steidanus wrote a 'Universal History,' in Latin; and Carrion composed a 'Chronicle' in German, about the middle of the sixteenth century. There are very few historical writers in this period: and we may conclude this notice by mentioning Puffendorf, who, besides his treatises on international law, wrote several historical works; and Herman Conring, who wrote on several historical and biographical subjects. Both these writers belong to the seventeenth century.

In the natural sciences the first place belongs to Conrad Gesner (born in 1516), who, on account of his great knowledge in all the branches of natural history, was named the German Pliny. In the sixteenth century Otto Guerike acquired a justly merited reputation by his invention of the air-pump.

To this period belong Kepler; Leibnitz, who however often preferred writing in French; and the learned Wolf.

Gottsched (1700—66) did a great deal towards purifying the German language and fixing its grammatical rules but he was too servile an imitator of the classics and of the French authors; and his excessive strictness in adhering to the rules laid down by the great literary authorities of antient and modern times led him into an absurd pedantry. Gellert (1715—69) introduced a better taste into German literature, particularly by his fables and tales, as well as his lectures on poetry and eloquence. Lessing (1729 81) powerfully contributed to the reformation of German literature by his criticisms as well as by his literary compositions. Gaertner (1712—91) did a great deal towards improving the taste of his countrymen and banishing many of the prevailing errors which obstructed the improvement of the literature of Germany. Rabener, who is well known for his satirical compositions, laboured towards the same end by attacking the pedantry and the assumption of some writers.

We shall here briefly enumerate the principal authors, beginning with the poets who have appeared in Germany since the middle of the last century, and at the same time give a rapid survey of their works, following the alphabetical order.

Charles Gustave Brinkman was born in 1764, in Sweden, but educated in Germany, where he afterwards spent a great part of his life in a diplomatic capacity. He published several poems in German, which are distinguished by great purity and harmony of language.

Bürger is the well-known author of Eleanora and other ballads. Claudius Mathius (1743—1815) wrote, under the name of Asmus, or 'the messenger of Wandsbeck,' numerous songs, ballads, elegies, and fables, characterized by practical good sense, wit, and humour, which gave them a universal popularity among all classes. The tendency of his writings is always moral, and calculated to promote religion, patriotism, and all the virtues, while he mercilessly lashes folly and vice. The productions of the latter part of his life show a strong tendency to mysticism, and are entirely opposed to the spirit of his early writings. His collected works were published in 8 volumes. Many of his songs were set to music, and are known over all Germany. John Andrew Cramer, chancellor of the university of Kiel (1723—88), wrote many lyric poems; his religious odes and hymns are the best. Michael Denis (1729—1800), a celebrated bibliographer, translated Ossian into hexameters, and wrote several poems in the stylo of Ossian, which he published under the name of the 'Poems of the antient German bards.'

Gessner, Solomon. [GESSNER, SOLOMON.]

J. W. L. Gleim (1719—1803), who is considered one of the best German poets of his time, distinguished himself, particularly by his fables, tales, epigrams, and songs for children. His collected works, in 8 volumes, have passed through several editions.

Göcking (1748—1828) wrote songs, allegorical poems, and epistles, but his reputation was chiefly established by the 'Songs of two Lovers,' which first appeared in 1777. They attracted the general attention of the German public, and were warmly eulogised by the best critics.

Goethe. [GOETHE.]

Gotter (1746-97) wrote tragedies, comedies, operas, epistles, tales, songs, &c, His works are distinguished by great perfection in their construction, but display no superior poetical genius.

J. N. Götz (1721-81) wrote with considerable success odes, elegies, idylls or eclogues, tales, and allegorical poems, which are characterised by great elegance, ease, and brilliancy.

Frederick Hagedorn (1708-54) acquired celebrity by his fables, tales, merry songs, and several minor poems. He may be considered as the first German poet who succeeded in this style of composition.

Haller, the celebrated physician and naturalist, wrote also many elegiac and didactic poems.

Herder. [HERDER.]

Hippel (1741—1796) is considered the first of the humorous writers of Germany. His works are rendered exceedingly attractive by the shrewd observations and thorough knowledge of human nature which the author displays, particularly in representing some well-known contemporary characters. He was most successful in satire, but his comedies, religious hymns, eclogues, and other poetical compositions, are by no means devoid of merit. His life and character were full of singularities, and exhibited the most striking contrasts. Unlike the generality of poets, he left at his death 140,000 dollars, although he began his career with scarcely any fortune.

Hölty (1748-76) is considered one of the best lyric poets of Germany, and his poems, particularly his idylls and elegies, are very popular in that country.

Anna Louisa Karsch (1722—1791), the daughter of a publican, who was married successively to a weaver and to a tailor, spent a great part of her life in struggling against the greatest misery, until she found some benevolent patron. She enjoyed for some time considerable reputation, but her poems are now nearly forgotten.

Kästner, a celebrated mathematician (1719—1800), was also known by his witty epigrams.

Ewald Kliest was born in 1731, and fell in battle in 1759. He wrote several poems, of which his 'Spring' acquired at once a universal popularity, which it still enjoys.

Klopstock. [KLOPSTOCK.]

Kosegarten (1758—1818) spent the greatest part of his life as a pastor of a parish, on the island of Rugen, where he devoted to literary pursuits all the time that was left to him from the duties of his avocation. In 1807 he became professor of divinity at the university of Griefswald, where he remained till his death. Besides some novels, he wrote many poems belonging to the so-called romantic school, which have attained considerable reputation in Germany.

Kotzebue. [KOTZEBUE.]

Lichtwer (1719-83) is a popular writer of fables.

Mathisson (1761—1831) was a lyric poet of considerable popularity, whose works are however more distinguished by skilful versification than by poetical genius.

Frederick Müller, known by the name of Painter Müller, was a painter, engraver, and poet (1750—1825). Besides some dramatic productions, he wrote chiefly elegies; his works are distinguished by passionate inspiration, and a successful delineation of character, although they are sometimes wild and incoherent.

Neubeck, a didactic poet, established his reputation by

his poem, entitled 'Mineral Wealth,' written in hexameters.

Baron Nicolay (1737—1820) was born and educated at Strasburg, but spent the greatest part of his life in Russia, where he was invited, in 1769, to superintend the education of the Prince, afterwards the Emperor Paul. He wrote fables, tales, elegies, epistles, and ballads, as well as some dramatic pieces, which were favourably received in Germany.

G. K. Pfeffel (1736—1809), brother of the celebrated political writer of that name, wrote numerous fables and tales, which attained some popularity.

Rammler (1725—98), a lyric poet, translator, and critical author. His works do not display any great poetical genius, but have the merit of extreme correctness, refined taste, and purity of language, and in these respects they may be considered as models. He translated Martial, Catullus, and Horace. Among his original poems the most successful is 'The Death of Jesus,' and some other lyrical productions.

Schiller. [SCHILLER.]

Christian Count Stolberg (1748—1821) wrote several dramatic pieces, and translated into German several of the Greek poets. He was particularly successful in the expression of tender feelings, and in painting domestic scenes. His works were published in twenty volumes at Hamburg, in 1821. His younger brother, Count Frederick Leopold (1750—1819), who far excelled him in poetical talent, is known as a poet by his odes, hymns, elegies, ballads, satires, and dramatic compositions; as a prose writer, by his novel, entitled the 'Island,' and by his travels through Germany, Switzerland, Italy, and Sicily. He acquired also considerable reputation by his translation of Homer; of some dialogues of Plato; and of some tragedies of Æschylus. His poems have a greater boldness of thought and more imagery than those of his brother. All his works are characterised by a glowing enthusiasm for nature, friendship, liberty, and all that is dear to a noble mind. The tone of his productions is very diversified, and ranges from the simple song to the fiery expression of the dithyramb. In his 'Life of Alfred the Great' he displayed an exact knowledge of Anglo-Saxon history. His conversion from the Protestant to the Roman Catholic religion produced a great sensation in Germany, and embroiled him with many of his friends.

Thümmel (1738—1817) gained a reputation by his comic heroic poem, although written in prose, 'Wilhelmina, or the Married Pedant.' He wrote several lyric poems, but his reputation was chiefly established as a prose writer by his 'Travels in the southern provinces of France,' a kind of novel full of wit and humour. The only fault of the work is its extreme length, 10 volumes.

Uz (1720-96) wrote various poems of different kinds, but his epistles, his merry poems, and religious hymns are his best productions.

Voss (1751—1823) is perhaps the best translator of the classical authors into modern languages that has appeared. He translated Homer, Virgil, Ovid, Horace, Hesiod, Aristophanes, Theocritus, Bion, Moschus, Tibullus, and some other minor authors, into German verse. These translations are remarkable for the fidelity with which they express the meaning, and frequently the peculiar character of the original. The difficulty of the undertaking and the author's success are perhaps in no instance better shown than in his happy translation of the most difficult parts of the 'Idylls' of Theocritus. In connexion with his sons Henry and Abraham, he also made a translation of the complete works of Shakspeare. Of his original works the most celebrated is his poem called 'Louisa,' which is a masterpiece in its kind. The subject is a description of the wedding of a country clergyman's daughter; the metre is hexameter and the style an imitation of that of Homer; and yet with these apparent absurdities it contains great beauties and is one of the most popular works in Germany.

Wieland. [WIELAND.]

Zacharia (1726-77) is one of the best comic poets of Germany, and his works are still held in high estimation.

The living writers of Germany defy all enumeration. The 'Pocket-book of Comedians,' published by Lambert (1823) mentions no less than 287 living dramatic writers. This will serve as a specimen of the number of individuals engaged in literary pursuits. It is almost needless to remark that a great mass of worthless books must be produced by such a host of writers. Many however have attained a well-deserved reputation. We shall briefly mention the principal writers, following the same order.

Chamisso was born in France in 1781, but emigrated in his childhood to Germany, where he received his education. He is a man of great information, particularly in the natural sciences. In 1815 he embarked in a voyage round the world as a naturalist to a Russian expedition, and on his return, in 1818, he received a situation at the botanical garden at Berlin, where he still remains. He has written several romances and ballads founded on popular traditions, which have had great success. He is considered one of the most national poets of Germany, although born a Frenchman. Chamisso is the author of the well-known tale of 'Peter Schlemihl,' which has been translated into several languages of Europe, and of which an English edition has appeared with designs by Cruikshank. Besides his works of imagination he has written a volume on his voyage round the world, and a work on the plants of Northern Germany.

Helmina Chezy, the widow of the well-known French Sanscrit scholar of the same name, and daughter of the celebrated German authoress Karsz, is considered by the Germans to be one of their first living poets.

Heine, a poet and political writer, born in 1797, is one of the most popular poets of Germany, and undoubtedly possesses great talents, although his style is full of inequalities, frequently passing from sublimity to vulgarity, and from deep feeling to an extreme frivolity. He has written two tragedies, 'Almansor,' and 'Radcliff,' besides many smaller productions. Amongst his prose works, his travelling sketches have a great popularity in Germany, but although they contain many beautiful descriptions, and witty and shrewd observations, they are often disfigured by great coarseness. Heine lives at Paris: his work on the political state of France has produced a general sensation in Germany.

Löben (Count), born in 1786, died 1815, belongs to the popular writers of Germany; he wrote chiefly ballads and tales.

Platen (Count), born in 1795, besides several dramatic pieces has written many other poems, particularly imitations of Oriental productions, which his great knowledge of the Persian language and literature has enabled him to do with considerable success. He is a general favourite with the public of Germany.

Pyrker is archbishop of Erlau in Hungary, where he was born in 1772. His epic poems entitled 'Pearls of the Holy days of yore,' 'Tunisias,' and 'Rudolfias,' though they cannot claim the merit of being faultless epic poems, contain great poetical beauties and show a very refined taste.

Rückert, better known under his assumed name of Freimund Reimar, born in 1789, is now professor of Oriental languages at the university of Erlangen. He is considered to be one of the best lyric poets that Germany has ever had. Besides a great many original poems he has made many translations from Oriental authors.

Schwab, born in 1792, is, next to Uglana, the most popular writer of romances and ballads.

Schenkendorf (1784—1817) is the author of several religious and patriotic poems which enjoy great popularity, and he would have perhaps become one of the first poets of Germany if his premature death had not cut short his literary career.

Tiedge, born in 1752, who is still living at Dresden, is one of the most popular authors in Germany. His poems are chiefly of the lyrical and didactic kind, and are considered scarcely inferior to those of Rückert. Many of his poems have been set to music by the first composers of Germany. An edition of his complete works was published in 1829, in eight vols.

Tieck, born in 1773, has written several poems, but is much better known by his critical works and by his translations of Don Quixote, several plays of Shakspeare, and of other old English dramatic writers. Tieck has written several humorous tales and dramas; he has published also a collection of poems of the antient Minnesingers, and thus introduced among his countrymen a taste for their antient literature.

Uhland, born in 1787, is one of the best lyric poets of Germany and exceedingly popular. He is also a learned antiquarian, and his work on Walter Von der Vogelweide, a celebrated Minnesinger, and his researches into the northern mythological Sagas of Thor, show a thorough knowledge of his subject.

Zeidlitz (Baron), born in 1790, has established his poetical

reputation by his dramatic and lyric productions. His poems entitled 'Wreaths of the Dead,' published in 1831, have had universal success. They have derived this title from being written in praise of eminent deceased persons. Amongst his dramatic works, published in four volumes, 1836, the best are 'Turturel,' 'Two Nights at Valladolid,' and the 'Star of Seville.' The most remarkable is however the drama entitled the 'Prison and the Crown,' of which the last days of the life of Tasso form the subject. Zeidlitz published, in 1836, a very well executed translation of Byron's 'Childe Harold's Pilgrimage.'

German Prose Writers.—The first historical work of any note that appeared in Germany during the eighteenth century was the translation of the 'Universal History,' published in England by a society of learned men, of whom the principal were Sale, Bower, Swinton, &c. The translation began to appear in German in 1744, at first under the superintendence of Baumgarten, and afterwards under that of Semler. But the imperfections of the original work being soon perceived in Germany, it was found necessary, after the publication of the early volumes, to make numerous corrections, the original being written with little or no historical discrimination and criticism. After the thirty-first volume, the German editors no longer followed the English text, but replaced it with original matter. Thus Schloezer wrote a general Survey of the Northern Countries; Meusel, the History of France; Le Bret, of Italy; Sprengel, of England: Galletti, of Germany; and Rühs, of Sweden. In this way the work increased to 78 large volumes in quarto, but it is not complete. It contains abundant materials for history, and some special parts are written with considerable ability. A translation of the 'Universal History' of Guthrie and Gray was also undertaken in Germany. But the German editors in this case also soon abandoned the English text, and substituted their own work for it. Heyne wrote for this collection the antient Asiatic, Greek, and Roman history, as well as that of the Arabs, Moguls, and Turks; Ritter described the period of the Roman and Byzantine emperors, and that of the first states which were founded by the Germanic nations; Schroekh wrote the history of Italy, France, England, and the Low Countries; Heinrick, the history of the Germans and of the German empire; Dieze, that of Spain and Portugal; Wagner that of Poland and the north of Europe; Gebhardi, Hungary and the countries connected with it. Johann Von Müller begun his history of the Swiss Confederation, with the view of making it a part of this collection, which contains a great deal of valuable matter, but, like its predecessor, the 'Universal History,' must be viewed as a series of special histories rather than as a universal history. Schroekh and Remer published several compendiums of universal history, which are written with considerable care, but they are deficient in those elevated views which constitute a true historian. Beck treated history according to a method peculiar to himself, in his 'Introduction to the Knowledge of Universal History,' a work which has not been completed. Busch wrote, in the style of a chronicler with great impartiality and research, but in a rather dry manner, and in an imperfect style, his 'Outline of the History of the most remarkable Events of Modern Time since 1440.' It was finished after the death of Busch by Bredow, and completed by Hegewisch, who added to it the antient history, and that of the middle ages. The 'Universal History' of Eichhorn enjoys a well-merited reputation, but it is surpassed by his 'History of the three last Centuries.' Heeren's 'Compendium of the History of the States of Antiquity;' of the 'European Political System;' and his 'History of European Colonies since the discovery of both the Indies till the establishment of the imperial dignity in France,' are all works of merit, though it must be admitted not free from objection as to the mode in which he handles his authorities and draws his inferences from them, especially in the first-mentioned work.

Raumer is considered as Heeren's rival by his 'History of Europe since the end of the fifteenth Century,' 4 vols., Leipzig, 1832-34.

The other German works on universal history which deserve mention are 'Sketches of Universal History,' by Dippold, 2 vols., Berlin, 1812; 'Survey of Universal Political History,' by Dresch; and the works of Poelitz, Schneller, Schlosser, Rotteck, and Menzel. The best compendiums of universal history for academic and school use are those of Wachler and Wachsmuth.

The special history of several nations and countries has been treated in Germany of late years with a degree of research, patient industry, and sound judgment, in which the Germans have surpassed all the rest of their European contemporaries. To this class belong Maylath's 'History of Austria, and that of Hungary.' Lappenberg's 'History of England' is only at its commencement, but what has already appeared shows an uncommon acquaintance with the historical sources for the Saxon period of our history. Von Hammer has written a history of the Turks, founded on Oriental authorities; Gejer, of Sweden; Kampen, of the Low Countries; Raumer, the history of the Hohenstauffen dynasty; Luden, Menzel, and Pfister, each a history of the Germans; Voigt, a history of Prussia; and Wilken, a history of the Crusades.

It would be beside our purpose to do more than indicate in a general way the spirit which characterizes the present historical school of Germany. To mention all the writers here would be impossible; but we must not omit to give to the patient industry of the German historians that praise which is justly due. Not only have the complicated events of modern times been subjected to a criticism, searching and minute as to details, and rich in results and general principles, but the same patient investigation has been carried to the study of antiquity. Instead of being a barren and ungrateful pursuit, it has become in the hands of the German philologists a rich and instructive study, peculiarly adapted to form the youthful mind to habits of careful investigation and accurate appreciation of evidence. Of the writers who have laboured in this department, it is enough to mention the names of Niebuhr, Wachsmuth, and K. O. Müller.

The Germans have produced many valuable works on the history of the human mind, on the progressive civilization of the human race, and on the history of literature and art. Adelung's 'Essay on the History of the Civilization of Mankind,' is a work of considerable merit, but is surpassed by Herder's 'Ideas on the Philosophy of the History of Mankind.' Jenist wrote a 'Universal Historical Survey of the Development of the Human Race as a progressive whole,' Berlin, 1801; and Eichhorn a 'General History of the Civilization and Literature of Modern Europe.' The same subject was treated with more or less success by Waltman, Stapfer, Pölitz, and Schneller, &c. Special branches of these subjects have been treated in the following works:—'History of the Origin, Progress, and Decline of Learning in Greece and Rome,' by Meiners; 'History of the Study of Classical Literature since the Revival of Learning in Europe,' by Heeren; but both these works remain incomplete; 'History of Poetry and Eloquence,' by Bouterweck, who likewise published a very valuable 'History of the Literature of Spain;' and other works on the history of literature, by Meusel and Waehler; the latter of whom wrote also a history of historical research and of the sciences. The two Schlegels occupy a distingushed rank as critics. The lectures of A. W. Schlegel on dramatic literature have been frequently referred to in the article Dramatic Literature.. In addition to Mosheim, who wrote, in Latin, ecclesiastical history has been treated by Schroekh, who devoted almost all his life to the composition of his 'Christian Ecclesiastical History,' in 35 vols.; to which must be added its continuation since the Reformation, in 10 vols., of which the two last were written by Tzchirner, 1826, the well-known author of many theological works of a polemical nature: his 'Fall of Paganism' was published after his death in an unfinished state, although he had spent twenty years upon it. 'The Universal History of the Christian Religion and Church,' by Neander, is generally esteemed. The subject of the antient religious systems is treated in Rhode's work 'On the Religious System of the Bactrians, Medes, and Persians;' and in his 'Essay on the Religious Civilization, Mythology, and Philosophy of the Hindoos.' Münter wrote a valuable work on the religion of the Carthaginians. The history of philosophy is treated in the compendiums of Eberhard, Gurlitt, Socher, and Tennemann; and in the extensive works of Tiedemann, Buhle, Tennemann, and H. Ritter. Fisher wrote a history of natural philosophy; Gmelin, of chemistry; Hoyer, of the military science; and Stäudlin, of the theological sciences. But the 'History of Medicine,' by Sprengel, is probably superior in real merit to any other work of the kind.

Geographical science has been most successfully culti-

vated in Germany: indeed we may say that Germany is its birth-place. Antient geography was treated for the first time by Cellarius in his 'Geographia Antiqua,' Leipzig, 1686, which has been since republished many times under the title of 'Notitia Orbis Antiqui.' This work is now no further useful than as showing the progress made since it was written. Among the many German writers on antient geography, the best works are—'Geography of the Greeks and Romans, founded on their Writings,' by Conrad Mannert, 10 vols., Leipzig, 1788-1820—a work of labour and research, valuable as all German works of the kind are for the authorities, but liable to the objection, in common with many other German works, of an inadequate estimation of them. 'The Geography of the Greeks and Romans, from the Earliest Times to Ptolemy,' by Ukert. A valuable contribution to the history of geography is the 'History of the most important Geographical Discoveries to the arrival of the Portuguese at Japan,' by Sprengel. 'The Comparative Dictionary of Antient Geography with that of the Middle Ages and Modern Times,' by Bishoff and Möller, is a very useful book for geographical students. Modern geography was for the first time treated on something like a system by Büsching, whose 'Universal Geography,' in 10 parts, 1754-92, was long considered a standard work. The numerous political changes which have taken place since the time of its publication have rendered it of little use even as a description of political divisions; and physical geography at that time hardly existed. Since the time of Büsching many valuable works on modern geography have appeared in Germany. The 'Universal Geography' of Shütz, in 30 vols., which appeared at Vienna, 1824-33, is a collection of special descriptions of all the countries of the world, by the most eminent writers. The first geographical writer in Germany is Charles Ritter, in Berlin, whose work, 'Geography in its relation to the Nature and History of Man, or Universal Comparative Geography,' is now in course of publication. The labours of Berghaus also demand honourable mention.

The first geographical dictionary in German was published by Hübner, 1740, under the name of the 'Zeitungslexicon,' or Gazetteer. It was however not a mere geographical dictionary, like the English gazetteers, but it contained articles relating to war and politics, which were the common topics of the gazettes. This work has been re-published many times; it appeared for the last time, with all the corrections and additions rendered necessary by the progress of events, in 1828, in 4 vols., at Leipzig. There are several works of a similar character in German: the 'Geographico-Statistical Lexicon' of Hassel; that of Schorch and Ehrman; of Jäger, &c.

Statistics first received a scientific form and method, as well as a name, from Achenwall (born in Poland, 1719), who began to lecture on this subject at the University of Göttingen, in 1749. A great number of German authors have since written on this important department of political knowledge. We may mention as the most distinguished of them, Schlötzr, Meusel, Hassel, Gatterer, Mannert, Sprengel, and several other authors, whom we have already enumerated among the historians and geographers of Germany.

Germany has produced many eminent writers on every branch of jurisprudence. The predominant school in that country is now the historical, which is divided into the Teutonic, chiefly represented by Fr. Ch. Eichhorn (son of the historian whom we have already mentioned), author of the 'Political and Legal History of Germany,' 4 vols., last edit. 1823; and the Roman, whose principal leader is Gustavus Hugo, professor at Göttingen, the author of many valuable works on Roman law. Savigny, perhaps the first of German jurists, is the author of several highly esteemed works, of which the history of the Roman law during the middle ages has appeared in an English translation. His valuable work on the right of possession, 'Das Recht des Besitzes,' Giessen, 1827, is, we believe, little known in this country, though it is undoubtedly one of the most exact analyses of a complicated legal question that has ever appeared. Among the great jurists of Germany, Thibaut of Heidelberg, the author of the 'System des Pandekten Rechts,' holds a distinguished place. Of the authors belonging to the Roman school may be mentioned Gans of Berlin, author of an historical work on the Law of Inheritance, and of some other treatises. Criminal Law has been treated by Feuerbach in a masterly manner, and by Mittelmeyer, Kleinschrod, Konopach, &c. The truly philosophic spirit in which the study of law is prosecuted in Germany as a branch of academic education and of political investigation, forms a striking contrast with the almost total neglect of legal and political studies in the English academic course of instruction.

The Protestant divines of Germany may be divided into three schools: 1, the Orthodox or Supernatural; 2, the Rational; and 3, the Pietist. The Orthodox or Supernaturalists may be subdivided into the decided Supernaturalists, whose religious conviction is entirely founded on the authority of a supernatural revelation, and which is chiefly represented by Tholuck, Hengstenberg, Guericke, Hahn, Harms, Olshausen, and Sartorius: and the Rational Supernaturalists, who found their belief in a supernatural revelation, not on human reason, but on historical authority, admitting human reason as a means to understand it; to this school belong Steudel, Schwarz, and Zöllick. The Rationalists may also be divided into two sections: the Decided Rationalists, who admit no other standard in judging of religious matters than human reason; such are Rohr, Wegsheider, Paulus, Gesenius, Shalthesr, Baumgarten Crusius, and David Schütz; and the Supernatural Rationalists, who admit a supernatural revelation, but consider human reason as the only test by which it ought to be acknowledged; this section is represented by Ammon, Böhme, Hase, and Köster. There are indeed many divines who do not belong either to the supernatural or rational school, but who pretend that there is no real contradiction between these two principles, which they think to conciliate by a philosophical explanation of the orthodox doctrines: there are also shades even in this party.

The Pietists form no separate school as regards doctrine, but belong to the orthodox or supernatural one. They are distinguished by a more strict adherence to religious observances, and greater zeal in all their views for promoting religion. They frequently adopt exaggerated notions about the duties and obligations of a Christian. Their number has lately much increased in Germany. Their views are advocated in several religious periodicals, and the most celebrated author of that party is Jung Stilling. The well-known Madame Krudener was a great promoter of the same party. In connexion with theology, the Germans have prosecuted with unwearied industry the study of the Hebrew, the Arabic, and other Oriental languages. The study of the Sanscrit and of Indian antiquities, which would seem to have peculiar claims on England, have been followed up in Germany with a zeal which ought to put to shame the nation that governs India. It is sufficient here to mention the names of Bopp, A. W. Schlegel, Rosen, Bohlen, and Lassen.

In pure philosophy the names of Kant, Fichte, Schelling, Hegel, and many others, reflect a lustre on their native land. German metaphysics however will scarcely find a numerous class of readers in any other country, and this, mainly owing to two causes; first, the difficulty of mastering the language so as to understand these writers; and secondly, the great extent of their works, which, as they are parts of a system, require to be studied completely. That no man can prosecute the study of the profound thinkers of Germany without deriving great improvement from the intellectual discipline to which he must submit, is undeniable; but a partial acquaintance with them, through the medium of inadequate translations, can only produce a superficial knowledge and a spirit of dogmatism.

In this rapid and imperfect sketch, our object has been, as in the article on French Literature, merely to present some general notions on what is commonly called the literature of the German nation; that in fact which, in every civilized country, gives us the best idea of a nation's character and mode of existence. That the industry and success of the Germans in prosecuting every branch of inquiry which relates to the phænomena of nature, have kept pace with their efforts in literature, hardly needs to be remarked. The prodigious mental energy of this people, as exhibited by the unwearied and apparently inexhaustible activity of the press, is unequalled in any other part of the world. What the men of other countries could do, if they would—if they had time enough, and patience enough, and zeal enough in their several pursuits—is done, and is daily in progress, in Germany. There seem to be two main causes of this mental activity of the Germans. One is, the number of sovereign states into which the country is distributed; and the other, the form of the political institutions. Con-

sequent on the first cause is the number of functionaries required for the various departments of administration, and of universities, schools, and other places of special instruction, where alone the qualifications required in such functionaries can be obtained. In addition then to the number of men constantly training for the functions of administration or for professions, there must be a great number of persons employed in teaching the various branches of knowledge required; and thus employment is given, with moderate salaries, to a larger body of men in proportion to the population than in any other country, while a situation in a university or other public place possesses the advantage of furnishing a man with a competency, though not enough to make him rich. His ambition is confined to his own sphere by the institutions of the country in which he lives, and he must earn distinction in that branch which he has made his business and his choice. The second cause, the want of political liberty, as it is called, in Germany, seems to have a very extensive operation in turning the industry and the thoughts of the Germans to those subjects where investigation is unfettered and the expression of opinion unrestrained. The great number of persons in Germany, who, under the circumstances just mentioned, receive a superior education, will help to explain, in some degree, a circumstance that at first excites some surprise:—we allude to the great number of special works which, from their subjects and the profound manner in which they are handled, would hardly find any readers in this country; so large however is the class of students in Germany who are profoundly versed in special branches of knowledge, that few really valuable works, we believe, on any subject, fail to find purchasers enough to defray, if not the whole, at least a large part of the expense of publication.

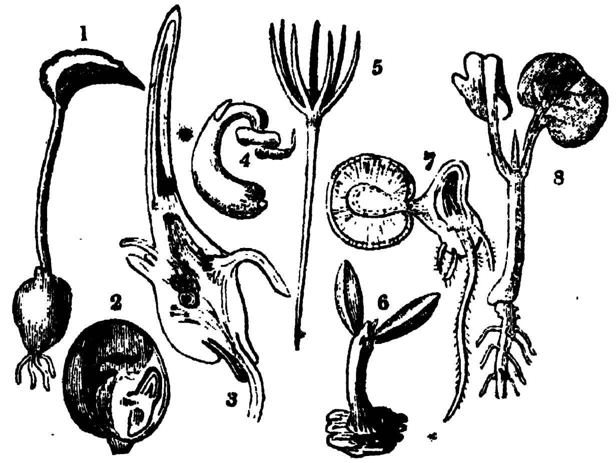
GERMEN, a name applied by the Linnæan school of botanists to what is now called the ovary of a flower.

GERMINATION, the first growth of a seed, the act by which it exchanges the condition of an embryo for that of a young plant. The embryo of a plant is folded up in the inside of a seed, and is either a short double cone on which two or more cotyledons are fixed, or a simple more or less cylindrical body having no apparent distinction between the cotyledons and the axis. [FŒTUS.] It has moreover little other than a cellular organization, very often not possessing a trace of the complicated vascular and tubular structure afterwards developed. The act of unfolding, breaking through the integuments of the seed, and acquiring a vascular and tubular as well as cellular organization, is germination. To bring this about three conditions are requisite: viz., a moderate degree of heat, very variable according to species; moisture; and communication with oxygen. Heat enables the moisture the more readily to dissolve the solid substances contained in the cells of the embryo, and a supply of oxygen provides the means of respiration. This being adjusted, the cells of the embryo dilate, their solid matter becomes fluid, and the carbon they contain combining with the oxygen forms carbonic acid, which is got rid of: the result of this is a diminution of the solidity of the embryo, a formation of sugar in its interior, of which advantage is taken in the process of malting, and a deterioration of the atmosphere. During this period the embryo would naturally be in a state of darkness, and so long as it continues to grow in darkness it parts with carbonic acid; but as soon as the young stems or leaves meet the light, carbonic acid is decomposed, oxygen is liberated, and a green colour is formed. At this period germination is accomplished.

The progress of development in the embryo is usually first for the radicle to lengthen, then for the cotyledons to unfold, and then for the plumule to extend into a stem (*fig.* 8); but in Endogens, the plumule of which is often enclosed in the very substance of the cotyledon, a somewhat different process takes place.

In Potamogeton lucens (*fig.* 4) the radicle gradually swells and lengthens, and at last produces from within its apex a papilla which becomes the root; the cotyledon, which is spiral, at the same time lengthens, and at last the plumule pierces through one side of the embryo. In Canna Indica (*fig.* 7) the cotyledon always remains inclosed in the albumen, merely swelling; the radicle and cauliculus are protruded from the seeds; the former turns downwards and emits a number of fine roots, the latter produces from within its substance a conical body, consisting of several sheaths one within the other, which are the rudiments of leaves. The Cocoa-nut differs from Canna chiefly in its cotyledon swelling exceedingly and becoming spongy, filling the whole cavity of the seed, and absorbing the milky fluid. Grasses offer only a slight modification of the same form. The embryo of maize, when divided vertically (*fig.* 2), appears like a fleshy plate lying on one side of the flowery albumen; at its back next the albumen is the cotyledon, next the skin is a cone of sheaths (as in Canna) forming the plumule, and at the base of the plumule another cone constituting the radicle. When such an embryo germinates, the radicular cone pierces the soil, emitting from its interior, through a kind of sheath, a few slender roots, and protruding others from its surface; and the other cone, representing the plumule, at the same time lengthens upwards in the form of a green spire, leaving the original external part of the sheath at its base (*fig.* 3).

Many anomalies in the development of the embryo of both Exogens and Endogens might be pointed out, but they are of little interest to any but professional botanists. Among the most striking are the following:—In the genus Pinus the cotyledons are numerous, and placed in a whorl (*fig.* 5); in the Cyclamen the cauliculus enlarges into a roundish turnip-like mass, from the apex of which spring the leaves and flowers, and from the base the roots (*fig.* 1); in mistletoe, a parasitical plant (*fig.* 6), the radicle becomes a flat plate, concave on the underside, by which it adheres to the bark of the plant it grows upon, and from which the singular roots proceed, which eventually insinuate themselves through the bark between the plates of living wood.



The manner in which the radicle protrudes itself is different in Exogens and Endogens. In the former its point gradually lengthens and becomes a new root; this is called *exorhizal* germination: in the latter the point of the radicle opens and allows the true root to escape from within it, a phænomenon to which the term *endorhizal* is applied. It will be obvious to those who have read what has been said under FŒTUS, that these differences depend entirely upon the manner in which the cotyledon is rolled round the axis of growth in Endogens, or distinguished from it in Exogens.

Attempts have been made to expedite the process of germination by steeping seeds in a weak solution of chlorine, but no practical advantage has been derived from the experiment. A more effectual plan has been found for hard-shelled seeds, such as those of the Acacia, namely, boiling the seeds for a period between one and five minutes. This has certainly, in some cases, had the effect of causing seeds to grow which under ordinary circumstances would not have grown; a circumstance to be ascribed, we conceive, to the hard integuments of the seed being so much softened as to offer no great resistance to the attempts of the embryo to escape from within them,—attempts which required no assistance when the embryo was in full activity and the seed-coat comparatively soft, but indispensable when these conditions are reversed by the loss of vigour in the embryo and the excessive induration of the case containing it.

GERONA. [CATALONIA.]

GERS, a department in the south of France, situated between 43° 16′ and 44° 5′ N. lat. and 1° 12′ E. and 0° 18′ W. long. It is bounded on the north by the department of Lot et Garonne; on the north-east by that of Tarn et Garonne; on the east and south-east by that of Haute Garonne; on the south by that of Hautes Pyrénées; on the south-west, for a short distance, by that of Basses Pyrénées; and on the west and north-west by that of Landes. The

form of the department is very compact: its greatest length, from east to west, is seventy-three miles; it greatest breadth, at right angles to the length, fifty-three miles: the area is computed at 2424 square miles, a trifle above the average of the French departments, and rather more than the conjoint area of the English counties of Chester and Salop. The population in 1831–32 was 312,160; in 1836, 312,882; this last calculation gives 129 inhabitants to a square mile, which is considerably below the average relative population of France, and very far below the relative population of the English counties compared with it. Auch, the capital, is on the Gers, in 43° 39′ N. lat. and 0° 35′ E. long., about 370 miles in a straight line south by west of Paris, or 479 miles by the road through Orléans, Limoges, Cahors, Montauban, and Toulouse.

Surface, Hydrography, Communications.—The surface of the department slopes gradually from south to north, and is traversed by several branches of the Pyrenees, which follow the same direction and become lower as they approach the northern limits of the department. None of them are much above 1200 feet in height. The most important of these branches is that which separates the basin of the Adour from that of the Garonne. The streams east of this branch flow either to the north or the north-east, into the Garonne, no part of which stream is in the department: the principal are the Bayse, and its tributary, the Losse; the Gers, the Rabs, the Gimone, and the Save. The streams west of the branch of the Pyrenees are, the Douze, the Midou, and the Arros, which have a north-west course, and belong to the system of the Adour; the Adour itself flows for a short distance through the department. None of the rivers in the department are navigable; nor is there water conveyance of any kind. There are eight *Routes Royales* (government roads), having an aggregate length of 258 miles, but not a mile and a half is in proper repair: the *Routes Départementales* (roads under the charge of the local administration) are seventeen in number, and have an aggregate length of 324 miles; four-fifths of these are in good repair. The *Chemins vicinaux* (bye roads and paths) are estimated at 6000, and are in length above 6000 miles. Of the government roads, one of the second class leads from Agen (Lot et Garonne) by Lectoure, Fleurance, Auch, Mirande, and Miélan to Tarbes and Barèges (Hautes Pyrénées); most of the others lead from Auch to different parts of the department.

Geological Character.—The supercretaceous strata occupy the whole department. No metals are found; but there are gypsum, potters' clay, brick earth, fullers' earth, and a fusible spar, used in the manufacture of glass; there are a few mineral springs.

Climate, Soil, Agricultural Produce, &c.—The climate is temperate and salubrious; frosts are of short duration, and snow is rare. The winds are variable; the south-east, south-west, and west predominate. Fogs are not unfrequent in May and June, and are considered injurious to the harvests.

The soil is of middling quality, and does not produce very abundant harvests. It is thus appropriated:—arable, 823,870 acres; meadows and grass land, 150,321; vineyards, 216,775; woods, 146,397; orchards, nurseries, and gardens, 15,065; osier-beds, willow-plots, &c., 642; variously occupied, 50,958; heaths, commons, &c., 88,197; pools, ponds, and ditches, 575; lakes, rivers, and brooks, 5641; forests and other non-productive lands, 3594; unascertained, 45,011: total, 1,547,046 acres.

The arable land is chiefly devoted to the growing of wheat; the quantity that is raised is very great; maize is grown to a considerable extent, also oats, rye, and pulse; some barley is grown, but this grain is not much cultivated in the south of France; potatoes are grown to a greater extent than in most of the southern departments, and cabbages and onions are grown on a large scale. The vineyards, though numerous, do not, with few exceptions, produce good wine; the produce of the vintage is chiefly converted into brandy, known as Armagnac brandy, and ranking next to that of Cognac in excellence. In the pastures are reared horned cattle, many sheep, a few horses, and a considerable number of asses and mules. An abundance of poultry is reared, especially ducks; the legs and wings of these are salted, and form an important store of provisions for the inhabitants, and their livers, which are of great size, make excellent pies. Game and wild animals (as the wolf and fox) are rare. There are few fish in the rivers, but more in the standing waters.

Divisions, Towns, &c.—The department comprehends a portion of Haut or Blanc Armagnac, the whole of Fezenzac, Fezenzaquet, Gaue, and Noir Armagnac, and portions of Eauzan, Riviere Basse, Brullois, Lomagne, Les Baronnies, Astarac, and the county of Ile-Jourdain: all these were subdivisions of the county of Armagnac. A considerable portion of Condomois, and a smaller portion of Comminges are also included in the department. Armagnac, Condomois, and Comminges, were all subdivisions of Gascogne.

The department is subdivided into five arrondissements, as follows:—

Capital.	Population in 1831	1836.	Situation.	Area. sq. miles.	Pop. of Arrondis. 1831.	1836.
Auch,	9,801	10,461	Central.	497	61,645	61,214
Lectouré,	6,495	6,355	N.E.	38[illegible]	53,641	52,605
Mirande,	2,532	2,532	S.W.	665	84,843	85,385
Condom,	7,144	7,098	N.W.	574	71,487	71,855
Lombez,	1,541	1,622	S.E.	306	40,544	41,823
				2,424	312,160	312,882

The department comprehends 29 cantons, and 498 communes.

In the arrondissement of Auch, besides the capital [AUCH] on the Gers, are Vic-Fezenzac, otherwise Vic-sur-Losse (population, 2574 town, 3679 commune) on the Losse; Pavie and Seissan, on the Gers; Castlenau-Barbarans and Aubiet, on the Rals; Sarramont and Gimont (pop. 2094 town, 2952 commune), on the Gimone; Barran, Biran, Jegun, Lavardens, Montant, and Pessan: none of these are of any importance.

In the arrondissement of Lectoure, are the capital Lectoure, near the Gers, Montastruc, Fleurance, and Casteras, on the same river: Mauvesin, Tournecoupe, and St. Clar, on the Rals; Solomiac, near the Gimone; Ligardes, Terraube, Le Mas, La Sauvetat, Cézan, St. Avit, Miradoux, Plieux, Montfort, Gaudonville, and Sarrant or Sarran. Lectoure, situated on an eminence, is an old and ill built town; but one of its *places* commands an extensive and magnificent prospect. A marble statue has been erected in the town to the memory of Lannes, duke of Montebello, who fell in the battle of Essling, A.D. 1809. The inhabitants manufacture leather, and carry on a considerable trade in corn, cattle, wine, and brandy. There are a subordinate court of justice, an hospital, a high-school, and an agricultural society. This town existed in the time of the Romans under the name of Lactora, and was the capital of the Lectorates or Lactorates, an Aquitanian tribe. In the third century after Christ Lactora was a Roman colony. Many Roman antiquities have been found here. In the Middle Age Lectoure was strongly fortified with a triple wall (of which there are some remains) and a castle. It was in the possession of the counts of Armagnac, who often resided here. Jean V., the last count, whose unbridled licentiousness and violence involved him in disputes both with Charles VII. and Louis XI., was besieged in Lectoure by the troops of the latter, and assassinated soon after the surrender of the town. At Fleurance is a fine market-place, in which are held eight considerable yearly fairs for corn and goose-feathers; the other places are unimportant.

In the arrondissement of Mirande are the capital, on the Bayse; Ile de Noé, or Ile Bayse, on the same stream; Beaumarchez and Plaisance, on the Arros; Miélan, Tilhac, or Tillac, and Marciac, on the Boues, a feeder of the same stream; Masseube, on the Gers; Vulla, Barcelonne, or Barcelone, Riscle, Aignan, Lupiac, Bassoues, and Montesquiou. Mirande was formerly capital of the district of Astarac; it is tolerably well built, and is still surrounded by walls in good repair. The neighbourhood is barren. The town carries on some trade in wine, brandy, wool, and leather.

In the arrondissement of Condom are the capital [CONDOM], on the Bayse; Valence, on the same river; Nogaro and Monguillem, on or near the Midou; Manciet and Cazaubon, on the Douze; Eause (pop. 3202 commune), on the Gelize, a tributary of the Lauboue, which flows into the Losse; Monréal, on the Lauboue; Le Houga, Lanepax, Gondrin, and Lialores. Eause, or Eauze, derives its name from Elusa, an antient city, which in the time of the Romans was the capital of the Elusates, and metropolitan see of Novempopulana, a district embracing all that part of Gaul which was S.W. of the Garumna, or Garonne. In the eighth or ninth century Elusa was destroyed by the Normans, and the metropolitan see was transferred to Auch, the diocese of Eause, the town which rose out of the ruins of Elusa, being a simple bishopric. The ruins of the Roman city, which preserve the designation of La Ciutat,

are a little way from the modern town. There are many distilleries at Eause and at Cazaubon. There are handsome baths at the mineral springs of Castera du Vivent, between Condom and Auch.

In the arrondissement of Lombez are the capital, on the Save; Samatan and Ile Jourdain (pop. 1579 town, 4307 commune), on the same river; Simorre and Villefranche, on the Gimone; Cologne, Touget, Montferrand, and Montpezat. Lombez was formerly capital of Bas Comminges. The neighbourhood is one of the most fertile spots in the department, but is liable to be devastated by the floods of the Save. Ile Jourdain had formerly strong fortifications, now dismantled, and a castle, now razed. The former counts of this town had frequent broils with the counts of Toulouse.

The population of the towns, where not otherwise noticed, is from the census of 1831.

The manufactures and commerce of the department are of little importance; they comprehend a few linens, woollens and cottons; some starch and glass: the distillery of brandy is of more consequence. There are several tanyards and flour-mills, and quills for writing are prepared in considerable quantity. Mules and horned cattle are exported to Spain.

The department constitutes the archiepiscopal diocese of Auch; it is comprehended in the jurisdiction of the *Cour Royale* of Agen; and in the circuit of the *Académie Universitaire* of Cahors; it is in the 10th military division, the head-quarters of which are at Toulouse; and sends five members to the Chamber of Deputies.

In respect of education, this department was a little below the average of France before the measures taken for the promotion of education within the last few years.

GERSON, JOHN CHARLIER DE, chancellor of the University of Paris, surnamed the Most Christian Doctor, was born in 1363, at the village of Gerson, in the diocese of Reims, from whence he took his name. He began his studies at Paris, where, having risen by degrees, he attained the place of chancellor of the university, and became canon of Notre Dame. France was during that period disturbed by civil wars, and all Europe was agitated by the religious contest between the popes and anti-popes. Gerson distinguished himself in his own country by loudly inveighing against the assassination of the duke of Orleans, which exposed him to a severe persecution from the duke of Burgundy's party. His house was pillaged by an infuriated mob, and he escaped with his life only by concealing himself for some time in the vaults of the church of Notre Dame. His courage was not subdued by this occurrence, and as soon as he resumed his functions he vigorously attacked, before the university and the clergy, the doctrines of Jean Petit, a doctor of the University of Paris, who defended the murder of the duke of Orleans as a legitimate act in a public oration delivered on the 8th March, 1403, where he maintained that it was permitted, and was even praiseworthy, to kill a tyrant; and that it was allowable to employ for the attainment of that object all possible means. Gerson zealously advocated the convocation of the council of Pisa by his memoir 'De Unitate Ecclesiæ.' At that council he distinguished himself by great firmness united with much prudence, when the two contending popes, Gregorius XII. and Benedict XIII., were deposed, and Alexander V. elected. It was on this occasion that he published his celebrated treatise 'De Auferibilitate Papæ.' He appeared at the council of Constance as the ambassador of Charles IV. king of France, and the representative of the French church and of the University of Paris. In that assembly he exercised an immense influence, particularly in the deposition of Pope John XXIII., who had succeeded Alexander V. In all his speeches and in all his writings he maintained that the church had the right to make reforms, not only with relation to her members, but even to her chief: that it had the right of convoking a council without the consent of the pope, whenever he refused to give it. He also maintained that it was necessary to convoke councils general as well as particular, to abolish the annates, and to extirpate simony, which was then very common, &c. By his influence he established as a basis of all the decrees of council the doctrine of the supremacy of the church over the pope in matters of faith and discipline. Gerson disputed at the Council of Constance with Huss, against whom he declared himself with violence. Though Gerson would have added to his reputation by preventing the martyrdom of the Bohemian reformers, it must be admitted that he was in many respects superior to the superstitions of his time. He strongly condemned in his treatise 'Contra Sectam Flagellatorum' the self-torments inflicted by those fanatics, which were zealously promoted by St. Vincent Fererius, to whom Gerson addressed his friendly remonstrances on that subject. In his work entitled [illegible] established the rules by [illegible]ich a true may be distinguished from a false revelation; and he is far from being favourable to the revelations of St. Bridget, which made a great noise in his time.

The revelations of St. Bridget, a Swedish nun (born 1302, died 1373), obtained a great celebrity. The Council of Basel commissioned the celebrated divine Cardinal Torguemada, or Turrecrimata, to examine into them, who, notwithstanding the contrary opinion of Gerson, recommended them to the approbation of the council, which gave permission to publish them for the edification of the faithful. These revelations were printed for the first time at Rome, 1475, and republished many times in several parts of Europe. The best editions are considered to be that of Antwerp, 1611, and those of Cologne and Rome, 1628. There are three French translations of that work, the first published at Lyon, 1530, under the title of 'Prophétie Merveilleuse de Mme. St. Brigette, jusqu'à present trouvée véritable;' the second, at Paris, 1624; the third, also at Lyon, 1649. An English translation, under the title of 'Certain Revelations of Saynt Briget, with an epistle of Saynt Bernard, called the Golden Epistle,' London, by Thomas Gofrey, 8vo., without date. An edition of the four revelations of St. Bridget was published by Richard Whytforde, London, 1531. There are besides in English, 'The most devout prayers of St. Brigette, touching the most holy passion of our Saviour Jesus Christ,' Antwerp, 1659; and a life of Saynte Brigette, R. Pynson, London, 1516.

The persecution of Gerson by the duke of Burgundy's party was so violent, that he durst not return to France, but was obliged to take refuge in Germany. He went from Constance, in the disguise of a pilgrim, to Bavaria, where he wrote his work 'De Consolatione Theologiæ,' on the model of the celebrated work of Boethius, 'De Consolatione Philosophiæ.' It is written both in prose and verse, and passed through many editions. The 'Imitation of Jesus Christ,' generally ascribed to Thomas à Kempis, appeared for the first time appended to a manuscript of Gerson's above-mentioned work, 'De Consolatione Theologiæ,' dated 1421. This gave rise to the supposition that he was the real author of that celebrated work: and indeed it is a very doubtful point whether this opinion is true or not, there being several high authorities which ascribe to him the authorship of that book. Gerson remained several years in Germany, after which he returned to France, and fixed his residence in a convent of the Celestine monks at Lyon, of which his brother was the superior, and where he died 1429, at the age of sixty-six. (*Biographie Universelle*; *History of the Council of Constance*, by L'Enfant.)

GERVASE OF CANTERBURY, an historian of the thirteenth century, was a monk of Christ Church in that city. His 'Chronicle of the Kings of England,' from 1122 to 1200, and a 'History of the archbishops of Canterbury,' from St. Augustine to Archbishop Hubert, who died in 1205, are his principal works. Both are published by Roger Twysden, in the 'Decem Scriptores.' Bishop Nicolson, in his 'English Historical Library,' 4to., London, 1776, p. 45, ascribes a more extended history to him, of an entire copy of which he thinks Leland had the perusal. MSS. of Gervase of Canterbury are preserved in the Cottonian Collection, Vespas., B. xix., and in the library of Corpus Christi College, Cambridge, cod. 438, both of good age.

GERVASE OF TILBURY, also an historian of the thirteenth century, received his name from Tilbury in Essex, where he was born. Several modern writers state him to have been the nephew of King Henry II., but it is more certain that through the interest of the Emperor Otho IV. he was made Marshal of the kingdom of Arles in France. Bale and Pits differ much in the account of his works. He certainly appears to have written a Commentary upon Geoffrey of Monmouth's History of Britain; a History of the Holy Land; a treatise, entitled 'Origines Burgundionum;' and a History of the Kings of England and France, comprised in a work entitled 'Otia Imperialia,' a fragment of which is printed with his name in Duchesne's 'Historiæ Francorum Scriptores,' tom. iii. p. 363. Manuscripts of the

'Otia Imperialia' are preserved in the Cottonian Collection, Vesp., E. i., and in the Library of C.C.C. Cambr., cod. 414; they comprise the treatises entitled 'Mundi Descriptio,' and 'De Mirabilibus Mundi,' ascribed to him as separate works. Nicolson, *Engl. Hist. Lib.* edit. 1776, pp. 50, 151, ascribes to him the 'Black-book of the Exchequer;' but Madox, who published a very correct edition of that work, gives it to Richard Nelson, bishop of London. (Tanner, *Bibl. Brit. Hib.*, p. 315; Nicholson, *Hist. Lib.*; Nasmith's *Cat. of the MSS. in C.C.C.C.*, p. 388; Madox, *Hist. Excheq.* 4to. edit., vol. ii., p. 338, &c.)

GERVILLIA, a genus of conchifers or bivalves, hitherto only found in a fossil state. M. Defrance first noticed the genus, which he named after M. de Gerville, who discovered in the Baculite limestone of Normandy the species on which the genus was established. M. Deslonchamps (*Mémoires de la Societé Lincenne de Calvados*, 1824) proposed several modifications of the character, so as to allow the genus to embrace four other shells in addition to the first-described species, *Gervillia solenoides*, viz.:—*Gervilliæ pernoïdes* (*Perna aviculoides*, Sow., 'Min. Con.,' t. 66), *Siliqua*, *monotis* and *costatula*, which are figured and described in the memoir. M. Defrance thought that the bivalve was furnished with a byssus, but M. Deslonchamps conceives that *Gervillia* has no opening for the passage of that appendage. 'Should this prove to be the case,' writes the reviewer of the memoir (*Zool. Journ.* vol. i.), 'which we are rather inclined to doubt, it will effectually separate the shells of this from those of the other genera of the *Malleaceæ*. Their nearest affinity is with those of *Perna*, from which they may be at once distinguished by possessing an apparently inner additional hinge, formed of several oblique teeth, variously disposed, according to the species.' Mr. G. B. Sowerby (*Genera of Recent and Fossil Shells*, No. 11), who judges the genus to have been marine from its associates, and who states that there is good reason for presuming that it was adherent by a byssus, gives the following

Generic Character.—Shell oblong, nearly equivalve, very inequilateral, and oblique; hinge line rather long, linear, nearly straight, with many irregular, rather transverse little pits, and teeth placed below the dorsal edge.

Mr. Sowerby regards it as an intermediate genus between *Avicula* and *Perna*. It resembles, he observes, the former in its general form and external appearance; whilst its hinge is somewhat like that of the latter, though sufficiently different to enable us to point out without difficulty the peculiarities by which it may at once be known.

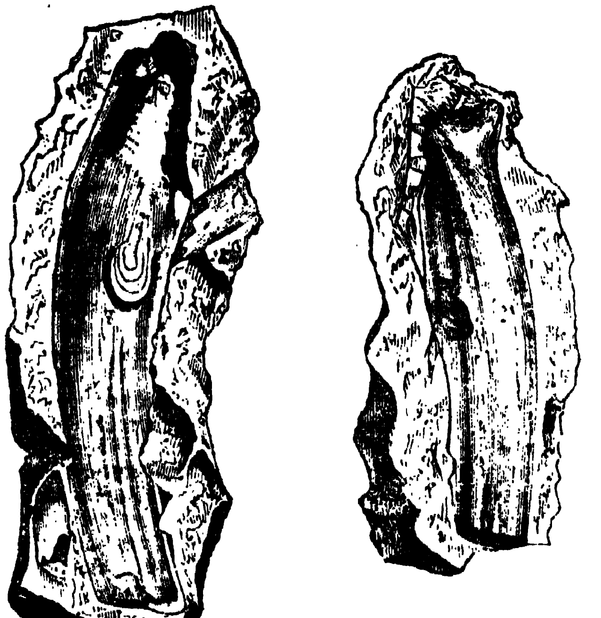
Cuvier, in his last edition of the 'Règne Animal,' places it under *Les Pernes* (*Perna* of Bruguières), between *Crenatula* and *Inoceramus*.

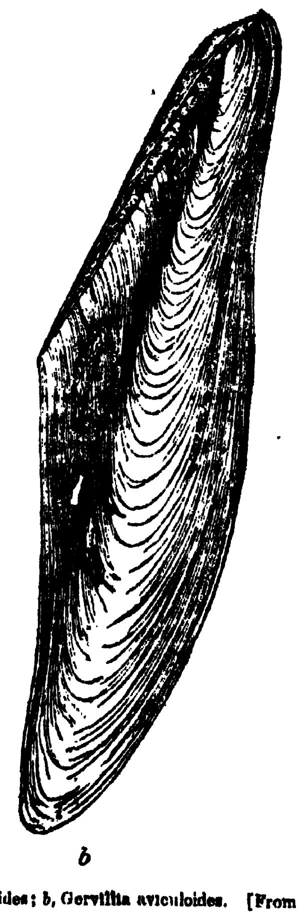
M. de Blainville arranges the genus under his family *Margaritacea* (the third of his *Acephalophora Lamellibranchiata*), between *Pulvinites* and *Avicula*. He notices that the shell gapes anteriorly, perhaps for the passage of a byssus, and describes the ligament as multiple and inserted in many conical fossæ forming a row within the hinge. He also describes the abdominal impression as single, and as rather anterior.

M. Rang gives *Gervillia* a place under the *Malleaceæ* of Lamarck, between *Malleus* and *Inoceramus*. In his description he notices the slight anterior opening as being doubtless (*sans doute*) for the passage of a byssus.

M. Deshayes, in his edition of Lamarck, notices the memoir of M. Deslonchamps, speaks of the multiple ligament and the single somewhat oval muscular impression placed towards the middle of the length of the shell and on the side of the dorsal edge, and remarks that, like the *Pernæ* and other genera of the family *Malleaceæ*, the *Gervilliæ* are covered externally with a delicate layer of fibrous matter, and that they may be regarded as *Pernæ* with an articulated hinge. The place assigned to them by M. Deshayes is between *Perna* and *Catillus*.

Mr. G. B. Sowerby observes that many species have occurred at various geological periods from the lias upward to the Baculite limestone of Normandy. M. de Blainville mentions the species as found in the department of La Manche. M. Deshayes says that they had not been found at the time he wrote (1836), except in the secondary beds. The genus occurs in the *Cretaceous Group* (Green Sand), and largely in the *Oolitic Group*. (De la Beche's *Geological Manual*; Dr. Fitton's *Systematic and Stratigraphical List of Fossils*, in his paper *On the Strata below the Chalk*; *Trans. Geol. Soc.*, 2nd series, vol. iv. 1836—read 1827; and the works of Conybeare, De la Beche, De Caumont, Defrance, Deslonchamps, Deshayes, Desnoyers, Dumont, Hoeninghaus, Holl, Lonsdale, Mantell, Münster, Murchison, Phillips, J. and G. Sowerby, Sedgwick, Thirria, Thurman, Voltz, and the German translation of De la Beche's *Manual*, &c.)





b

a, Gervillia solenoides; *b*, Gervillia aviculoides. [From Sowerby's Genera.]

GERVI'SIA (Zoology), a name given by MM. Quoy and Gaimard to a genus of small mollusks approximating nearly to *Pleurobranchus*.

GERYO'NIA. (Zoology.) [MEDUSA.]

GESNER, CONRAD, an eminent scholar and naturalist, who was a shining example of the truth of the remark, that those who have most to do and are willing to work find

most time. Beginning his career under all the disadvantages attendant on poverty, sickness, and domestic calamity, and cut off at the early age of 48, Gesner left behind him, notwithstanding the cares of the medical profession, which he actively and successfully exercised, such an amount of literary labour as would have won for him the title of one of the most learned and industrious of men, if his useful life had been occupied solely in its production. Zürich was his birth-place, where on the 26th of March, 1516, he came into the world to add to the difficulties of his parents, who were struggling to support a large family. His father appears to have been a skinner or worker in hides; and his mother's name was Friccius or Frick. To his maternal uncle, John Friccius, he seems to have been indebted for kind assistance and tuition:* but this good relation died—the father was killed at the battle of Zug (1531), when the son was only 15—and the poor lad, after struggling with a dropsical disorder, set out for Strasburg to seek his fortune. He was among strangers; but his spirit bore him up, and, in the service of the well-known Lutheran, Wolfgang Fabricius Capito, he resumed the study of the Hebrew language, which he had begun to learn at Zürich. On his return to Switzerland the academy of Zürich allowed him a pension, which enabled him to travel in France. At Bourges, where he stayed a year, Greek and Latin principally engaged his attention, and to assist in defraying his expenses he taught in school. From Bourges he proceeded to Paris, where he does not appear to have done much; and, after a short stay at Strasburg, whither he was led by the hope of employment, the university of Zürich sent for him, and he became a teacher there. He now married, at the age of 20, not with the approbation of his friends, who saw that his income could not be equal to his wants.

The church was his destination, but the strong impulse of his mind stimulated him to the study of physic, to which he determined to apply himself with a professional view; and, resigning his situation at Zürich, he went to Basel as a medical student, his pension being still continued. Here he seems to have commenced his labours for the public in superintending the edition of the Greek dictionary of Favorinus (Phavorinus). A wish to be intimately acquainted with the works of the Greek physicians led him to the acquisition of that language; and he laboured with such earnest zeal and success that he was offered the Greek professorship in the the newly-founded university of Lausanne, an appointment which he accepted. He afterwards passed a year at Montpellier, where he formed an intimate acquaintance with Laurent Joubert, the celebrated physician, and Rondeletius, the great naturalist. His emoluments were now not only adequate to his expenses, but moreover enabled him to prosecute the medical and botanical pursuits so dear to him; and at Basel, in 1541, or, as others say, in 1540, he took his degree of doctor in medicine Zürich was the field of his practice, which enabled him to cultivate his taste for natural history. He founded and supported a botanic garden, collected a fine library, made numerous drawings, and gave constant employment to a painter and to an engraver in wood. In the midst of his laborious profession, the astonishing industry of the man found time for the principal works on which his fame rests He lived honoured and respected for his talents and benevolence in his native town, till an attack of the pestilence which he had successfully combated in the cases of others, and to which his professional activity most probably exposed him, carried him off in his 49th year. When the plague-boil appeared in his axilla, accompanied by the worst symptoms, he knew that his death was certain. He desired to be carried to his museum, where, amidst the treasures he had collected and surrounded by the old familiar objects of his studies, he breathed his last in the arms of his affectionate wife, for whose conjugal love and piety contagion and death had no terrors, with the calmness of a Christian philosopher. This excellent woman survived him. Gesner left no children.

Thus died Gesner on the 13th of December, 1565, on the fifth day of the attack. His remains rest in the cloister of the great church at Zürich, near those of his friend Frisius. He was bewailed in abundance of Latin and in some Greek verses. Theodore Beza was among the most elegant of these tributaries; and his funeral oration was pronounced by Josias Simler, who wrote his life (1566, 4to.), of which Gesner himself had given some details in his *Bibliotheca*. De Thou in his great history speaks of him with high and deserved praise; but perhaps the most complete biography is that of Schmiedel, prefixed to Gesner's botanical works. He must have been much lamented by his contemporaries; for, in addition to his other amiable qualities, he appears to have been a general peace-maker,—his calm, candid, and amiable temper enabling him to soothe the angry feelings of authors under their real or imagined wrongs. Then again he would lay aside his own labour to assist others; and he devoted his time to the supervision and publication of Moiban's work on Dioscorides for the emolument of his deceased friend's family. Similarity of taste attached him to Valerius Cordus, who died at Rome in 1544, at the age of twenty-nine, whilst on his travels; and the *Historia Plantarum* of the latter was subsequently edited by Gesner, who however appears never to have had a personal interview with Cordus. It was otherwise with David Kyber, with whom Gesner was very intimate, who died of the plague at Strasburg in 1553, and whose *Lexicon Rei Herbariæ Trilingue* was published in that year by the same indefatigable editor, with an epistle to the father of the author full of affectionate consolation.

In the year 1545 Gesner journeyed to Venice and Augsburg, where he made the acquaintance of many learned and meritorious men; and this leads us to the literary works which have justly rendered Gesner's name famous, for then it was that he commenced the publication of his *Bibliotheca Universalis*, a grand design, and the first modern bibliographical work upon a large scale. As it was the first, so it may be, hitherto at least, said to be the last; for though an approach was made to it in Dr. Robert Watt's *Bibliotheca Britannica*, that useful and well-executed work is, as might be expected, conversant chiefly with English books. [BIBLIOGRAPHY, vol. iv., p. 381.] Gesner's *Bibliotheca* was a catalogue of Greek, Latin, and Hebrew works, with criticisms, and frequently specimens of the author quoted, and appeared in 1 vol. folio (1545, Zürich). The volume 'Pandectarum, sive Partitionum Universalium' (1548) may be considered as the second of the *Bibliotheca*. Gesner never published the book relating to medical works, because he did not consider it to be sufficiently perfect. An abridgment of the *Bibliotheca* by Lycosthenes, and completed by Simler and J. J. Fries, was published in 1583 (folio). Haller's *Bibliotheca Botanica* and *Bibliotheca Anatomica* were probably imagined from Gesner's work.

But the *Historiæ Animalium* must be considered the great work of Gesner. These well-filled folio volumes appeared at Zürich in the following order: Viviparous Quadrupeds (1551); Oviparous Quadrupeds (1554); Birds (1555); Fishes and other Aquatic Animals (1556),—this volume contains the labours of his contemporaries and friends Belon and Rondelet, with some additions by himself; Serpents (posthumous and published by James Carron, a Frankfort physician, 1587)—this is more rare than the other vols., and there is usually added a treatise on the Scorpion, posthumous also, and published in the last-mentioned year at Zürich by Caspar Wolf. There is also an edition in German. Of the 'Insects,' some inedited figures of butterflies are all that are known; but that Gesner had not neglected this class of animals is manifest from Mouffet's *Insectorum, sive Minimorum Animalium Theatrum: olim ab Edoardo Wottono, Conrado Gesnero, Thomaque Pennio, inchoatum* (fol., Lond., 1634), which is partly made up from Gesner's fragments. The work does not comprise the Mollusks and Testaceans as a class.

All agree that this compilation, having for its object nothing less than a general history of animated nature, concentrating and critically revising all that had been done before the time of the author, enriched with his own knowledge, and illustrated by many incidental remarks in the departments of botany and medicine, might have been considered as evidence of most persevering and praiseworthy industry, if it had been the production of a recluse whose long life had been entirely spent in the task; whereas it was only one of many books written by a man who gained his subsistence by perhaps the most harassing and time-consuming of all professions, and who died in harness when he was not forty-nine years old.

Gesner, in this work, which he carried out to completion as far as the *Vertebrata* are concerned, followed the method of Aristotle; and though there is not any establish-

* Some of his biographers state that John James Ammian, professor of rhetoric at Zürich, took him to his house and offered to defray the expense of his education, and that he remained with the professor three years studying diligently.

ment of genera, it may be considered as the principal source of more modern zoology, from which succeeding writers drew largely, and of which their publications mainly consisted. Thus it was copied in many parts, almost literally, by Aldrovandus; and Jonston's *Historia Naturalis* is little more than an abridgment of it.

Gesner's *Historiæ* were compressed and appeared under the titles of *Icones Animalium*, &c. This book is much more common than the original.

Passing by the various learned treatises that flowed from Gesner's prolific pen, we must notice the complete translation of the works of Ælian (1556). Gesner's notes also appear in the edition of Gronovius (London, 1744), &c.

This extraordinary man is next presented to us in another point of view; for he is said to have designed and painted more than 1500 plants. A large share of the 1500 figures prepared by Gesner for his 'History of Plants,' and left at his death, passed into the *Epitome Matthioli*, published by Camerarius in 1586; and in the same year, as also in a second edition in 1590, they were used as illustrations of an abridged translation of Matthiolus, bearing the name of the *German Herbal*. The same blocks were used by Uffenbach (1609) for the Herbal of Castor Durantes, printed at Frankfort, and comprising 948 of Gesner's. After the death of Camerarius, Goerlin, a bookseller of Ulm, purchased the blocks, and they embellished the *Parnassus Medicinalis Illustratus* of Becker (Ulm, 1633). In 1678 they found a place in Bernard Verzacha's *German Herbal*; and they appeared again in the *Theatrum Botanicum* (Basel, 1696), and in an edition of that work so late as 1744.

Besides the above, Gesner is said to have left five volumes, consisting entirely of figures which, together with his botanical works in manuscript, became at last the property of Trew of Nuremberg, and were published under the care of Dr. Schmiedel, physician to the margrave of Anspach (Nürnberg, 2 vols., folio, 1751-1770).

In closing our notice of this amiable, learned, and industrious man, it may not be uninteresting to state that, according to Haller, it is probable that Conrad Gesner was the first short-sighted person who aided the defect of his eye with concave glasses. Plumier dedicated to him a genus of plants of the family *Campanulaceæ*, under the name of *Gesnera*. [GESNERACEÆ.]

GESNER, JOHN MATTHIAS, born near Anspach in 1691, became rector of the school of Weimar, and was afterwards professor of eloquence and poetry at Göttingen. He distinguished himself as a classical scholar. His principal works are: 1. 'Novus linguæ et eruditionis Romanæ Thesaurus, 4 vols. fol., Leipzig, 1749, a useful compilation. 2. 'Primæ lineæ Isagoges in Eruditionem universalem, nominatim Philologiam, Historiam et Philosophiam, in usum prælectionum ductæ,' 2 vols. 8vo., Leipzig, 1775. 3. 'Biographia Academica Gottingensis,' 3 vols. 8vo., 1769. 4. A good and handsome edition of the antient Roman writers on agriculture: 'Scriptores Rei Rusticæ veteres Latini, Cato, Varro, Columella, Palladius, quibus accedit Vegetius de Mulo-Medicina, et Gargilii Martialis Fragmentum,' 2 vols. 4to., Leipzig, 1735, with Notes variorum, and an Index, or Lexicon Rusticum. He published also editions of Horace, Quintilian, Claudian, &c., and of Philopatris 'Dialogus Lucianeus,' with a dissertation on the authority and age of the same. Gesner died at Göttingen in 1761.

GESSNER, SOLOMON, born at Zürich in 1730, and a painter by profession, distinguished himself both as a painter and a poet. His first publication was some pastoral poems, 'Idyllen,' which had a considerable success at the time, but they are rather tame, and have the fault of all compositions of the same kind, that of representing a state of society which does not exist. His 'Tod Abels,' 'The Death of Abel,' written in prose, has ensured to its author a more lasting reputation. He has taken his subject from the impressive event recorded in Genesis, the first visitation of death upon mankind, and that death a murder. In his narrative he has given full scope to his poetical fancy, without however overstepping the boundaries of probability, or laying himself open to the charge of profaneness. But the genuine pathos of the sentiments and the sketch of the patriarchal manners constitute the great charm of the work. The character of Mehala, Cain's wife, is peculiarly interesting. His 'First Navigator' is also a pleasing fiction. Gessner enjoyed much popularity in his lifetime, both among his countrymen and among strangers, and his works were translated into various languages. His habits were simple and domestic. Madame de Genlis gives a curious account of a visit that she paid to Gessner at his country-house near Zürich, and of the interior of his family. Condorcet has written his biography. Gessner died at Zürich in 1787. His correspondence and miscellaneous poems were published after his death. Gessner engraved several of his own landscapes, which are much esteemed. His countrymen have erected a monument to his memory, with his bust, in one of the public promenades at Zürich, near the banks of the Limmat.

GESNERA'CEÆ, a natural order of monopetalous Exogens, allied to Scrophulariaceæ, and with them forming a portion of the Dicarpous group. [EXOGENS.] They are principally characterized by having an ovary more or less inferior, and a parietal placentation. They inhabit the hot and damp parts of South America, and in some cases overrun trees with their rooting stems, in the manner of ivy: the prevailing colour of their flowers is scarlet; some however are purple, as the Gloxinias, and others pale green, as Sinningia and Drymonia. Many beautiful kinds are known in our gardens; and several other magnificent species are figured in Von Martius's 'Nova Genera et Species Plantarum,' vol. iii. They are of no known use.

Leaves and flowers of Gesnera grandis. 1, a corolla laid open to show the interior; 2, a calyx, with the projecting style; 3, a transverse section of a capsule.

GESTURE. [ORATORY.]

GETA, ANTONI'NUS, younger son of the Emperor Septimius Severus, born about A.D. 190, was made Cæsar and colleague with his father and brother A.D. 208. The most remarkable circumstance recorded of him is the dissimilarity of his disposition from that of his father and brother, who were both cruel, while Geta was distinguished by his mildness and affability. He is said to have several times reproved his brother for his proneness to shed blood, in consequence of which he incurred his mortal hatred. When Severus died at Eboracum (York), A.D. 211, he named both his sons as his joint successors in the empire. The soldiers, who were much attached to Geta, withstood all the insinuations of Caracalla, who wished to reign alone, and they

insisted upon swearing allegiance to both emperors together. After a short and unsuccessful campaign against the Caledonians, the two brothers, with their mother Julia, proceeded to Rome, where, after performing the funeral rites of their father, they divided the imperial palace between them, and at one time thought of dividing the empire likewise. Geta, who was fond of tranquillity, proposed to take Asia and Egypt, and to reside at Antioch or Alexandria; but the Empress Julia, with tears, deprecated the partition, saying that she could not bear to part from either of her sons. After repeated attempts of Caracalla to murder Geta, he feigned a wish to be reconciled to his brother, and invited him to a conference in their mother's apartment. Geta unsuspectingly went, and was stabbed by some centurions whom Caracalla had concealed for the purpose. His mother Julia tried to screen him, but they murdered him in her arms, and she was stained by his blood and wounded in one of her hands. This happened A.D. 212, under the consulship of two brothers of the name of Asper. After the murder Caracalla began a fearful proscription of all the friends of Geta, and also of those who lamented his death on public grounds. [CARACALLA.] (Spartianus, in *Historia Augusta*; Herodianus, book iv.; Dion, book 77.)

Coin of Geta.

British Museum. Actual size. Copper. Weight, 312 grains.

Reverses of Coins of Geta.

GETÆ, the name of a northern tribe mentioned in Roman history, inhabiting the country on both banks of the Danube, near its æstuary, and along the western shores of the Euxine. Those who lived south of the Danube were brought into a kind of subjection to Rome in the time of Augustus (Dion Cassius, book 51), and their country, called Scythia Parva, and also Pontus, is well known under the latter name through the poems which Ovid, in his exile, wrote from Tomi, the place of his captivity. He gives in many places a dismal account of the appearance and manners of the Getæ, especially in elegies vii. and x. of the 5th book of his *Tristia*. The maritime part of the country had been in former times colonized by the Greeks: and this may account for the partial civilization of the Getæ south of the Danube, whilst their brethren north of the same river remained in a state of barbarism and independence The Getæ are described by Herodotus (iv. 93) as living in his time south of the Ister (Danube): he calls them the bravest of the Thracians. Some have confounded the Getæ with the Dacians; the latter however lived farther in the interior and west of the Alpes Bastarnicæ, or the Carpathians, in the country of modern Transylvania, whilst the Getæ were to the east of those mountains and between them and the Euxine, occupying the southern parts of the countries now called Bessarabia and Moldavia, on both banks of the Porata or Pruth, and extending from the Danube to the Tyras, or Dniester, which separated them from Sarmatia. Strabo distinguishes the Daci from the Getæ, though he says that both spoke the same language. [DACIA.] The Goths who, under the conduct of Odin or Woden, conquered Scandinavia, came also from the shores of the Euxine, and are supposed by some to have had a common origin with the Getæ. [DANES.]

GEUM, a genus of Rosaceous plants, distinguished from the strawberry by the receptacles of the carpels being dry, and those bodies, when ripe, being furnished with hardened hooked hairy styles, so that the collection of them in each flower resembles a bud. A very common species is the Avens, or Geum urbanum, a perennial hedge-plant with small yellow flowers, and erect hairy branched stems, covered with 3-lobed wedge-shaped notched leaves, having large rounded lobed green stipules at their base. The root of this plant is aromatic and astringent, and is thought to offer the best indigenous substitute for Jesuits' bark. It is said to communicate an agreeable clove-like flavour to beer and wine.

GEYSERS. [ICELAND.]

GEX, a district of France, on the frontier toward Geneva. It was ceded to France by the Swiss in 1601, and was included, with the adjacent districts of Bresse, Bugey, and Valromey, in the military government or province of Bourgogne. Under the Empire it was comprehended in the department of Léman; but when, at the peace of 1814, France lost the greater part of that department, the district was included in the department of Ain. The country of Gex is wholly mountainous, being traversed by the ridges of the Jura, and is bounded on the south-east by the Rhône, which is not here navigable. The inhabitants live on chesnuts for a considerable part of the year. They carry on some trade in cheese, wine, wool (they have large flocks of merinos), and coal.

Gex, the chief town, is on a small stream which flows into the Rhône, and on the high road from Paris to Geneva by Dijon and Dôle. It is small, consisting of one broad main street on a slope. Population in 1831, 1750 town, 2834 commune. Between Gex and Geneva is Ferney, the residence of Voltaire, whose house is still standing.

GHARRA. [HINDUSTAN.]

GHAUTS. [HINDUSTAN.]

GHEBRES. [GUEBRES.]

GHEE, a species of butter used by the natives of India, and prepared by boiling, so that it will keep for a considerable time; it is sometimes used when a year old. The milk, when first taken from the animal, is boiled in earthen pots for at least an hour, and frequently for two and even three hours: it is then allowed to cool, and a little curdled milk, called Tyre, is added to promote its coagulation. By the next morning the whole mass has been converted into tyre, or coagulated acid milk. About five or six inches in depth are then taken from the top of each pot and put into an earthen jar, where it is churned by turning round in it a split bamboo with a very quick motion. After half an hour's churning, some hot water is added, and the operation is continued for another half-hour, when the butter forms. When this butter has been kept two or three days, and has become rancid, as it will during that time in so hot a climate, it is melted in an earthen pot, and boiled until all the water that may be mixed with it is evaporated; a little tyre and salt, or betel-leaf, is then added, and it is put into pots to be kept for use. It has a strong smell, and although very distasteful to Europeans, is in general consumption among all the natives who can afford to buy it. Ghee is a very important article of internal traffic through a great part of India.

GHEEL, or GHEELEN, a town in the province of Antwerp, situated on the Great Nethe, 25 miles E. from the city of Antwerp, and 12 miles S. from Turnhout. It contained in 1830, 1068 houses and 7038 inhabitants, four churches, the largest of which was built about the beginning of the 11th century, seven chapels, and a townhall. From time immemorial Gheel and its neighbourhood have contained a considerable number of insane persons, whom it is the custom to send there from different parts of the country. These unfortunate persons are placed in private families, where they receive the greatest kindness and attention, and to such a point is the good feeling of the inhabitants carried upon this subject, that if any person were found wanting in consideration for the afflicted persons under his charge, they would be taken away and placed with some other family; and such is the moral effect of such a proceeding, that the stigma would be felt as the greatest punishment. The familiarity which, by long habit, the inhabitants of

Gheel have with insanity, has led them to understand the best mode of treatment for each particular state of the disorder, and has enabled them to adopt the most efficacious means for controlling their patients, so that it is exceedingly rare to find any, after even a short residence, exhibit signs of violence. Chains and every other instrument of bodily restraint are unknown among them. The patients almost invariably mix with the family, and employ themselves in the same occupation with those under whose care they are placed, enjoying all the liberty which can safely be given to them. This mode of treatment is said to be followed by the happiest results. The insane persons sent to Gheel are of almost every rank. The chief number is composed of indigent persons sent from the hospitals of other towns, and although the payment for them is extremely small, their treatment is in all respects as kind as is used towards others who are more profitable inmates.

GHENT, properly *Gent*, or *Gend*, and by the French called *Gand*, a city in Belgium, the capital of East Flanders, twenty-three miles south-west from Antwerp, twenty miles south-east from Bruges, and twenty five miles north-west from Brussels, in 51° 3′ N. lat., and 3° 43′ E. long.

The city is built at the confluence of the Schelde and the Lys, and is intersected by a great number of navigable canals which communicate with those rivers, and thus form twenty-six islands connected with each other by numerous bridges. The Sas-van-Ghent canal, which runs from Ghent towards the north into Zealand, where it joins the Neuzen canal, connects Ghent with the West Schelde, and allows sea-going vessels, drawing eighteen feet water, to enter the city. The canal of Sas-van-Ghent was originally intended only for carrying off the superfluous waters of the province, and its adaptation to navigation was determined upon while the work was in the course of execution. The canal was begun and finished in two years. The city of Ghent contributed a million of francs towards the cost; the remainder was furnished by the general government. It was opened for use in December, 1828.

The origin of Ghent, as well as that of many other towns in Flanders, is very doubtful. Some writers assert that the city which existed at the time of the irruption of the Vandals into Belgium in the fifth century, received from them the name of Vandle, which was afterwards changed to Ganda or Gandavum Castrum. This is mere tradition, but it is supposed to receive confirmation from the existence of a fort on the left bank of the Schelde within the city, bearing the name of Wandelaers Kasteel (Castle of the Vandals). About the year 629, king Dagobert sent St. Amand to Ghent to convert its inhabitants from paganism, and he founded two monasteries to the honour of St. Peter, one on a rising ground called St. Peter's Mount, the other near the Antwerp Gate. Many of the inhabitants, who were converted to Christianity by the preaching of St. Amand, bequeathed their wealth to the second of these monasteries. One of these benefactors gave his name to the abbey of St. Bavon, some part of the ruins of which building are still visible: this quarter of the city for some time bore the name of St. Bavon.

In 868 Baldwin Iron-arm, the first count of Flanders, built a fortress at Ghent, which was called Count's Castle. In 941, the first church was built and consecrated to Saint John the Baptist. Eight years after this Otho emperor of Germany entered Flanders at the head of an army, and destroyed everything with fire and sword. In the year 968, Baldwin the Younger, count of Flanders, introduced the art of weaving into Ghent. In 1046, Baldwin of Lille made himself master of the Count's Castle. About this time the city was visited by an epidemic disorder, which carried off more than 600 persons daily.

About the end of the twelfth century, the Flemish nobles, in order to equip themselves with splendor for the Crusades, sold their domains to their vassals, who by that means were enfranchised. Such of them as resided in Ghent proceeded to establish a form of municipal government; they elected sheriffs, adopted a public seal, and established a court of justice. They obtained at this time various privileges in favour of their trade and manufactures, and joined the association of the Hanse Towns. They further obtained from the emperor Frederick I. the free navigation of the Rhine. In 1180 Ghent, which was then a populous city, became the capital of Flanders, and obtained a charter from Count Baldwin of Hainault, with great privileges. The preamble to this charter contains the following remarkable words:—'It is conformable to the law of God, and to the light of reason, that princes who desire to be honoured and served by their subjects should consider it on their part a duty to respect and maintain inviolate the rights and customs of the latter; and it is with these considerations that at the desire of my dear and faithful citizens of Ghent I have assured to them in manner following their rights and customs, as well as the freedom of their city.' The first article of the charter declares that 'The citizens of Ghent owe to their prince fidelity and attachment while he shall treat them conformably to justice and reason, by which mode of acting alone the prince can reign for the advantage of all.' By a regulation passed in 1202, the citizens were disabled from acquiring estates beyond certain very confined limits around the city, which circumstance is said to have been productive of great prosperity to its manufactures. In return for this restriction, the citizens were secured in the monopoly of employments within the city, and for a certain distance round; and all who were unprovided with the means of living independently, or of contributing by their skill to the prosperity of the city, were expelled from it. Considerable inducements were held out to induce foreigners to bring their skill and capital, and to settle among them.

By these means the city increased so rapidly, that towards the end of the thirteenth century it exceeded in extent and population the capital of France. At the beginning of the fifteenth century, the number of its citizens employed in the manufacture of woollens is said to have amounted to 40,000, and in times of war furnished from their number 18,000 men under arms. Charles V., afterwards king of Spain and emperor of Germany, was born at Ghent, in February, 1500. During his reign the city contained 35,000 houses, and a population of 175,000 souls. In 1537 Maria, sister of Charles V., who then administered the government of the Netherlands, de[illegible]d from Flanders an extraordinary subsidy of 1,20[illegible] florins of gold, one-third part of which was to be paid [illegible] the citizens of Ghent, who, having already advanced [illegible]ble sums to the emperor towards the expen[illegible] the war with France, refused to comply with this fresh demand, and made a show of armed resistance, but were speedily reduced to submission; and the emperor, to punish the citizens, took away from them all their privileges, besides confiscating the property of such as had been actively concerned in the revolt, several of whom were condemned to death. On this occasion a citadel was erected for the purpose of holding the citizens in check.

When the confederation was formed for expelling the Spaniards from the Belgian provinces, a congress was held in Ghent; and a document known in history as 'the pacification of Ghent' was publicly signed by the confederates met together in the town-hall, 8th November, 1576. On the 11th of the same month, the Spanish garrison shut up in the citadel capitulated to the citizens. This citadel was afterwards destroyed.

The capitulation signed 17th September, 1584, again placed Ghent under the dominion of Spain; the citadel was rebuilt, and so many of the inhabitants quitted the city that one-third of the houses were empty. In 1598 the Belgian provinces were severed from the crown of Spain in favour of Isabella, daughter of Philip II., who married Albert, son of the emperor of Germany. Ghent was taken by Louis XIV. in 1678, after a siege of six days. The city was occupied by Marlborough in 1706. In 1745 Louis XV. having entered Flanders with Marshal Saxe at the head of 100,000 men, took Ghent by surprise, but the country soon again came into possession of Austria. In 1792 the Netherlands fell under the power of France, and Ghent was constituted the capital of the department of the Schelde, and so continued till the downfal of Napoleon in 1814, when Flanders became part of the kingdom of the United Netherlands. In 1814 the treaty of peace was signed here between Great Britain and the United States of North America, which put an end to the war between the two countries.

Ghent is a handsome well-built city. On the 1st of January, 1830, it contained 11,823 houses, inhabited by 16,438 families, comprising 39,543 males, and 44,240 females. It is surrounded by walls, and has seven entrance gates. The Brussels gate, called also the Emperor's gate, in memory of Charles V., was originally built in 1300, and restored in 1523. The Courtrai gate was destroyed in 1783 by order of Joseph II., and rebuilt in 1803, when it received the name of the Napoleon gate. St. Peter's gate, built in

1430, was reconstructed in 1827: it was through this gate that the French, under Count Lowendahl, entered the city by surprise in 1743, after the battle of Fontenoy. The gate of St. Lievin, the patron saint of the city, was built in 1300: the ruins of this gate are all that remain at this time. The Antwerp gate, built in 1570, and rebuilt in 1782, was taken down in 1828 in the progress of some improvements, and again rebuilt in 1830; the architecture of this gate is much admired. The old Sas-de-Gand gate, rebuilt in 1426, was much injured; it has lately been taken down, and its reconstruction ordered. The Bruges gate presents nothing remarkable in its appearance.

There are several fine promenades in the interior of the city. The finest is on the bank of the canal cut in 1758 to connect the river Lys with the Bruges canal, and called the Coupure. It is planted with three rows of large trees, and is much frequented in spring and autumn. The Boulevards which surround the city are also much used as public walks. The Friday market is a large square space, with a very old tower, in which meetings of the citizens were formerly held, and where criminals are executed. A large iron ring is fixed there in which pieces of cloth found imperfect by examiners are exposed previous to their being given to the hospitals. In the centre of the square, the citizens erected, in 1600, a column fifty feet high to the memory of Charles V. This column was surmounted by a statue of the emperor: it was restored in 1772, and taken down during the revolutionary troubles of 1793.

The cathedral church of St. Bavon, a fine Gothic edifice, was consecrated in 941. Its rebuilding was undertaken in the thirteenth century, but was not entirely finished until the beginning of the sixteenth century. It was formerly dedicated to St. John, and took the name of St. Bavon in 1540, when Charles V. caused the collegiate chapter of the abbey of St. Bavon to be removed to it: twenty years afterwards the church was constituted a cathedral. The tower is remarkable both for its elegance and its height, which is 271 feet. The spire, which was of wood, was destroyed by lightning in 1603, and has not been replaced. The numerous chapels in this cathedral contain some fine paintings, many of which were carried off by the French, but restored after the peace in 1817. One of these pictures, a chef-d'œuvre of Rubens, represents the reception of St. Amand into the abbey of St. Bavon, after having distributed his goods among the poor. The church of St. Michael, situated in the centre of the city, on the bank of the Lys, is built in a light and delicate style of architecture. It contains the only picture by Vandyck which is possessed by the city of Ghent; the subject is the Crucifixion. The parish church of St. James also contains several good paintings. There are many other churches within the city, several of them very antient, and many among them contain paintings and sculptures of considerable merit.

The palace of the university of Ghent, an institution founded by royal ordonnance in 1816, stands on the banks of the Lys. The first stone of the building was laid in August, 1819, and it was finished with great rapidity. The façade is composed of eight columns, of the Corinthian order, copied from those of the Pantheon. The building is large and commodious, and is well furnished with philosophical apparatus and specimens of natural history. The library contains about 60,000 volumes, besides numerous valuable manuscripts taken from suppressed abbeys and convents. This library is open to the public every day except Sunday, for six hours during summer and five hours in winter. There is a botanic garden founded out of the municipal funds, and now attached to the university.

The number of students in the university in 1832 was 292, of whom 141 were students in medicine, and the remaining 151 attended the law classes. An industrial school was founded by the government in 1825, and annexed to the university. The Royal College of Ghent occupies the greater part of the antient abbey of Baudeloo, a vast and very commodious building, in which several of the students as well as the professors reside. The total number of pupils is about 150. The Royal Academy of drawing, painting, and architecture occupies the antient college of the Augustines, to which building additions were made at the cost of the city in 1827. The students who avail themselves of the advantages offered by this institution are very numerous, and amounted in 1833 to more than 700. The studies comprise, besides linear and ornamental drawing, geometry, arithmetic, perspective, and anatomy, as applied to sculpture and painting. The collection of statues in the academy is considered to be valuable. There is also an extensive gallery of paintings taken from the suppressed abbeys and convents in 1795.

Ghent contains 21 public hospitals, besides several private establishments for benevolent purposes. The hospital of Byloke has accommodation for 600 patients, and ordinarily contains 200. This institution was established in 1225. The school for the poor, founded by the magistrates of the city in 1623, contains 150 youths, who receive an education suitable to artisans. Each scholar is instructed in some particular branch of industry. A similar establishment was founded at the same time for poor girls, and is still in existence.

There were in 1832 six communal and 101 private schools in Ghent: the former contained 562 boys, and the latter 1808 boys and 974 girls, together 3404 scholars.

Among the numerous benevolent institutions which Ghent possesses, its charitable workshop—*atelier de charité*—may be mentioned. The end proposed by this institution is the extinction of mendicity. It was established in 1817 by means of subscriptions raised from benevolent individuals, aided by the local government. Any person out of employment, and in a state of indigence, is admitted to work in the establishment. Those who are in health receive wages proportioned to the work they perform, while the payments to invalids or infirm persons are made more with reference to their wants than to the produce of their labour. Separate workshops are appropriated to males and females.

The central prison of Ghent, situated in the Coupure, is remarkable for its size and its judicious arrangements. It was built at two periods; the first part in 1772, at the cost of 48,000*l*., defrayed by the province, the second in 1824, at the cost of 40,000*l*., paid out of the general treasury of the kingdom. Instead of the idleness which in general characterizes the prisons of England, this establishment has all the appearance of a busy workshop. Weaving, and its necessaries of spinning and winding, are the most common employments of both males and females. The two sexes are separated. The women are also employed in washing and mending the clothes of the prisoners, and in the other necessary household duties. One quarter of the prison, which is kept altogether distinct from the rest, is occupied by prisoners confined for short periods as a punishment for small offences, and these prisoners are further classified with reference to their age, to the description of their offences, and the previous rank in life of the individuals. The building will hold 2600 prisoners, but has not hitherto contained more than half that number at any one time. This prison, so far from being a cause of expense, brings in an annual profit to the city of 4000*l*. (50,000 florins). A considerable portion of their earnings is given to the prisoners, part at the time and the remainder at their discharge from prison. This portion is deposited as it is earned in a Savings' Bank, and bears 4 per cent. interest, which is added to the principal, and is given with it to the discharged prisoner.

About 19,000 persons are employed in various occupations connected with the cotton manufacture, in spinning, weaving, bleaching, and printing. It is calculated that the capital embarked in this branch of industry amounts to 1,700,000*l*. Sugar-refining is carried on to a considerable extent in 24 establishments. This branch of industry has of late been much stimulated by means of the bounty given by the Belgian government on the exportation of refined sugar. The rate of duty paid on the importation is equal to fifteen shillings sterling per cwt., and the annual consumption of the kingdom is estimated at twelve millions of kilogrammes, equal to about 11,800 tons, which should therefore yield 177,000*l*. to the treasury. Nearly the whole of this sum is however given in the form of a bounty to the exporters of refined sugar, the revenue from this source having been reduced in 1837 below 5000*l*. It is attempted to justify this course under the plea of giving encouragement to the mercantile navy of Belgium, but it is expected that the growing deficiencies in the revenue, which at length has reached the point just mentioned, will lead to a considerable modification of the present system.

Among the various manufactures carried on in Ghent may be placed those of Valenciennes lace, silk weaving, salt refining, paper-making, woollen-cloths, tanning, bleaching, soap boiling, and pin-making.

Beside the Friday market, horse-fairs are held in Mid-Lent, and on the 23rd of July; there is also a general fair in August.

Ghent is the residence of the governor of the province; it is also the seat of a tribunal of first resort, and of a court of appeal, which last has jurisdiction over the whole province: it is likewise the residence of a bishop.

From returns printed by the former Netherlands government, it appears that the increase of the population of this city by natural means, between 1700 and 1814, was 18,647, the births having amounted during that period to 195,405, and the deaths to 176,758. The mean terms are therefore 1699 birth and 1537 deaths; the greatest number of births (2169) occurred in 1811, and the greatest number of deaths (2780) in 1809. The number of births and deaths in the first and last years of the series respectively were, in 1700, 1662 births and 1021 deaths; in 1814, 2038 births and 2499 deaths. The actual number of inhabitants in 1814 was 62,226. During the next sixteen years the increase was 21,557, or about 35 per cent., equal to a mean annual increase of 2⅙ per cent., showing that a considerable part must have proceeded from immigration.

GHIBELINS. [DANTE; FLORENCE.]

GHIBERTI, LORENZO. Of this sculptor, who makes an epoch in the history of Italian and modern art generally, the precise year of his birth is not known, for though Vasari states it to have been 1380, it is more probable that it was rather earlier; and accordingly some of his later biographers have presumed it to be 1378. He was born at Florence, where he received his first instructions in drawing from his stepfather Bartoluccio, who practised *oreficeria*, a branch of art at that time in high repute, and extending to designing all kinds of ornamental work in metals. He also acquired some practice of painting in his youth, and executed a fresco in the palace of Pandolfo Malatesta at Rimini, in 1401, the year following that in which he left Florence, on account (as he himself informs us in the memoir relative to the competition for the bronze gates of the Baptistery) of a pestilence in the city, and the distressed state of affairs. We learn from the same source that he applied himself with great diligence and ardour to this task, his mind being almost entirely engrossed by painting; but hardly had he completed it when a circumstance took place which proved the means of his signalizing himself, not only as the greatest sculptor of his own times, but as one whose works have excited the admiration of after ages. This was no other than the competition for a second pair of bronze doors for the Baptistery at Florence, worthy to accompany those executed by Andrea Pisano about 1340. This memorable competition attracted all artists of any eminence, and from among their number, seven, including Donatello, Brunelleschi, and Ghiberti, were chosen to make trial of their skill, the subject given them being the Sacrifice of Isaac, to be executed in bas relief as a model for one of the panels. Of the designs produced on this occasion only two have been preserved, namely those of Ghiberti and Brunelleschi, both of which are engraved in Cicognara's 'Storia della Scultura.' Neither of them is free from a certain stiffness in the attitudes, but Ghiberti's exhibits greater elegance in the forms and more judicious composition; Brunelleschi himself not only felt the superiority of his rival, but generously avowed it, and refusing to take any share in the work, solicited that all the sculptures might be entrusted to Ghiberti alone. These doors, which contain twenty compartments, or panels, filled with as many reliefs, consisting of scriptural subjects, besides a profusion of ornamental work in the intermediate spaces, obtained from Michel Angelo the well-known eulogium, that they were worthy to be the gates of Paradise. Yet a modern critic (Von Rumohr), whose discrimination, as well as his intimate acquaintance with early Italian art, entitles his opinion to more than ordinary respect, says that although they display great invention and admirable skill, they in some respects fall short of those by Andrea Pisano, who treating his subjects with greater simplicity, and more conformably with the principles of sculpture, avoided the confused and crowded appearance which prevails in those of Ghiberti. The latter, he goes on to say, give us the spirit of painting working upon materials belonging to the plastic art: so that in order to be fully appreciated and enjoyed, they ought to be looked upon as pictures rather than as mere sculptures—for as such their author evidently conceived them.

Remarks of a similar tendency have been made by others, who have objected to the attempt to give the effect of perspective and distance by means of various degrees of relief as utterly futile, because the parts which are nearly in full relief must inevitably throw shadows on those next them, although these latter may be intended to represent objects at a considerable distance beyond them. On the other hand these productions of Ghiberti display extraordinary genius, an attentive study of nature, and a sudden emancipation from that formal traditionary style of design and composition which had till then been adhered to by the Italian masters of that period.

He afterwards executed for the same building another pair of bronze doors, containing ten reliefs upon a larger scale, representing various subjects from the Old Testament, those of the first door being entirely from the New. Being thus limited as to their number, he endeavoured to render each history as complete as possible, by combining in each compartment four distinct actions. In the first, for instance, he has introduced the creation of Adam, that of Eve, their disobedience in tasting the forbidden fruit, and their expulsion from Paradise: amounting in all to a great number of figures. Among his other works may be mentioned the admirable bronze relief in the Duomo at Florence, representing San Zenobi bringing a dead child to life, and the three bronze statues of St. John the Baptist, St. Matthew, and St. Stephen, at the church of Or San Michele in the same city. He also painted on glass and executed some of the windows in the Duomo. He was even appointed Brunelleschi's coadjutor in the erection of the cupola of the edifice just mentioned: and was consulted by artists and their patrons upon every important undertaking. The exact time of his death is not known, but it is supposed to have happened shortly after he made his will, which was dated November, 1455, when he was about 77 years old.

Several of the bas-reliefs of the second or larger door of the Baptistery, namely, that facing the Duomo, have been engraved by Piroli for a work on the monuments of Modern Italy, previous to the time of Raffaelle; and a very interesting kind of artistical biography of him, including notices of all his most celebrated contemporaries, has been published by August Hagen, under the title of 'Die Chronik seiner Vaterstadt vom Florentiner Lorenz Ghiberti,' 1833.

GHILAN. [PERSIA.]

GHIRLANDAIO (Dominico Corradi, called Del), from the profession of his father, one of the old Florentine painters, was born in 1451, and died in 1495. He was fertile in invention, and later artists often made use of his works. He was one of the first who, with some correctness of outline, gave character to the face; and was the first Florentine whose works evince a due knowledge of perspective. His greatest works, consisting of events in the lives of St. Francis, the Virgin Mary, and St. John the Baptist, are in the Sassetti chapel, the church of the Holy Trinity, and the choir of the church of Santa Maria Novella. His brothers, David and Benedetto, were not equal to him. His son Ridolfo, who died in 1560, aged seventy-five, was a pupil of Fra Bartolomeo and a friend of Raphael, some analogy with whose genius, but with inferior powers, may be traced in his pictures. Dominico has the honor of numbering among his pupils Michel Angelo Buonarotti.

GHIZNI. [AFGHANISTAN.]

GHOOLGHOOLA is a remarkable hill in the valley of Bameean. This valley is situated in Afghanistan, to the north-west of the town of Cabul, at a distance of about 30 or 40 miles. It extends, in general, east and west, and has acquired notoriety on account of the great number of excavations in the mountains which enclose the valley on both sides, but the greater number of the caves on the northern face. The hill of Ghoolghoola, which is detached and in the middle of the valley, is quite honey-combed with excavations, and consists of a continued succession of caves in every direction. Not far from it are two colossal statues, a male and a female, cut out in the mountain-rock; they are in alto-rilievo on the face of the hill. The male figure is about 120 feet high, and the female about 70 feet. They are without symmetry, nor is there much elegance in their drapery. (Burnes's *Travels to Bokhara.*)

GHUNPORE. [HYDERABAD.]

GIANNO'NE, PIETRO, born at Ischitella, in the province of Capitanata, in 1676; studied at Naples, and applied

himself to the profession of the law. From the profits of his practice he managed by assiduous labour and economy to purchase a small country-house, where he spent all the time he could spare from his professional occupations, and where he wrote his great work, 'Storia Civile del Regno di Napoli,' 4 vols. 4to., 1724. Unlike most other historians who had preceded him, and whose narratives were merely chronicles of kings and wars and battles, Giannone laboured particularly to investigate the history of civil institutions, the laws, the manners, and government of the various countries which were afterwards united by the Normans into one state, called by the various names of the dukedom of Puglia and Calabria, Sicily citra Pharum, and lastly kingdom of Naples, and then to describe the changes in the institutions of the monarchy under the Normans, the Swabians, the Anjous, and the Aragonese, and in the time of Charles V. and the Spanish conquest. He next relates the events of two centuries of the Spanish vice-regal administration down to the year 1700. 'Storia del Reame di Napoli,' 1834, by Colletta, is a continuation of Giannone's work. One principal object of Giannone was to draw the distinction, so long left undefined, between the spiritual and the secular powers, and to show by what means and gradual steps the church of Rome, or rather its hierarchy, had trespassed upon those limits, until at last, 'having invaded every civil jurisdiction, it strove to render the empire wholly subservient to the priesthood.' (*Storia Civile*, b. i. ch. 2.) The profound learning of the author in the history and practice of the jurisprudence of the dark and middle ages, and the frequent citation of his authorities, constitute the chief merits of the work. In other respects he has been charged by some and not unfriendly critics with occasional historical and chronological inaccuracies; with borrowing without acknowledgment from Costanzo, Summonte, and other writers who had preceded him: and also with displaying throughout his work a spirit of fixed hostility to the clergy not always restrained within the limits of historical impartiality. But the pretensions of the ecclesiastical power were in Giannone's time so exorbitant, their encroachments so formidable, and their intermeddling so vexatious, as to sour the naturally irritable temper of Giannone, who felt already, and was also warned by his friends, that his boldness would cost him dear. Naples was then under the dominion of the Emperor Charles VI., whose government was rather favourable to Giannone's views: this however did not prevent the author from being assailed, after the publication of his work, by the clerical party, and being openly insulted in the streets of the capital. Being obliged to leave Naples, he went to Vienna, where the Emperor assigned him a small pension out of the Neapolitan treasury. Meantime his book was solemnly condemned by the Inquisition at Rome, and a monk wrote a refutation of it, in which he undisguisedly asserted the absolute authority of the Pope over the temporal state:—*Della Potestà Politica della Chiesa: Trattati due del Padre G. A. Bianchi contro le Nuove Opinioni di Pietro Giannone*, 5 vols., Rome, 1745. In the year 1734 the Austrians lost the kingdom of Naples, and Giannone, who lost his pension at the same time, repaired to Venice in quest of employment, but he there incurred the suspicion of the government, and was ordered away in 1735. He then took refuge at Geneva, where he completed a work which he had begun at Vienna, called 'Il Triregno, ossia del Regno del Cielo, della Terra, e del Papa,' in which he no longer confines his attacks to the temporal pretensions of the papal see, but impugns also several dogmas of the Roman Catholic church. The book was never printed, though MS. copies of it were circulated, and a copious extract of it is found in the biography of Giannone by Leonardo Panzini. Giannone however was, or thought himself, all the while a Catholic; and as he wished to take the sacrament at Easter, and there was then no Catholic church at Geneva, he listened to the advice of a pretended friend from Savoy, who invited him to pass over the border of the Genevese territory to a neighbouring village, where he could perform the sacred rite. The advice was treacherous; Giannone, as soon as he entered the territory of Savoy, was arrested, in 1736, and taken to the castle of Miolans, from whence he was transferred to the fortress of Ceva, and lastly to the citadel of Turin, by order of the king of Sardinia. He was treated however with some degree of attention, but never recovered his liberty, and he died in the citadel of Turin, in March, 1748, at the age of 72, after 12 years of imprisonment. During his captivity he had conferences with a priest, after which he abjured the opinions which had been condemned by Rome, and was consequently relieved from the interdict by the Inquisition. After the accession of Don Carlos of Bourbon to the throne of Naples, that sovereign sent for the surviving son of Giannone, and assigned to him a liberal pension, stating by an edict, dated Portici, 8 May, 1769, 'that it was unbecoming the interest and the dignity of his government to leave in distress the son of the most useful subject and the most unjustly persecuted man that the age had produced.' (Corniani, *Secoli della Letteratura Italiana*; Botta, *Storia d'Italia*, b. xli.) The views of Giannone concerning the total emancipation of Naples from the temporal jurisdiction of the see of Rome were fully acted upon and enforced by the administration of King Charles and his son Ferdinand IV. Giannone's 'Opere Postume,' chiefly in his own defence, were published at Lausanne after his death.

GIANT (γίγας), a man of great or unnatural stature. In the following article we shall mention those deviations from nature which sometimes occur in the proportions of the human form, both as regards the arrest or excess of development; and thus include the description of Dwarfs, or men who are unnaturally small, and beneath the usual size, as well as of Giants, who exceed the ordinary proportions of the human race. In considering this subject we will first allude to the question,—whether the size of man generally was ever different from what it is at the present time? Secondly, we will inquire if it is probable that races or nations of giants or pygmies ever existed? Lastly, we will state the ordinary proportions of the human frame, and enumerate a few examples of men who have much exceeded or have fallen far short of the common standard, and inquire whether these peculiarities of stature can be accounted for in any satisfactory manner.

It is a very common opinion, that in the earlier ages of the world men in general possessed superior physical properties, and were of a greater size than they are at present; and this notion of diminished stature and strength seems to have been just as prevalent in ancient times as at present. Pliny observes of the human height (vii., 16), that 'the whole race of mankind is daily becoming smaller:' a most alarming prospect if it had been true. Homer more than once makes a very disparaging comparison between his own degenerate contemporaries and the heroes of the Trojan war. But all the facts and circumstances which can be brought forward on this subject tend to convince us that the human form has not degenerated, and that men of the present age are of the same stature as in the beginning of the world. In the first place, though we read both in sacred and profane history of giants, yet they were at the time when they lived esteemed as wonders, and far above the ordinary proportions of mankind. All the remains of the human body (as bones, and particularly the teeth), which have been found unchanged in the most antient urns and burial places, demonstrate this point clearly. The oldest coffin in the world is that found in the great pyramid of Egypt, and Mr. Greaves observes that this sarcophagus hardly exceeds the size of our ordinary coffins, being scarcely six feet and a half long. From looking also at the height of mummies which have been brought to this country, we must conclude that the people who inhabited Egypt two or three thousand years ago were not superior in size to the present inhabitants of that country. Lastly, all the facts which we can collect from antient works of art, from armour, as helmets and breastplates, or from buildings designed for the abode and accommodation of men, concur in strengthening the proofs against any decay in nature. That man has not degenerated in stature in consequence of the effects of civilization is clear; because the inhabitants of savage countries, as the natives of America, Africa, Australia, or the South-sea islands, do not exceed us in size. It has been supposed that before the deluge men might have been of a larger form than they are at present, as they are said to have lived to a much greater age, but this is a mere assumption, unsupported by any evidence whatever.

When investigating the subject, whether any peculiar races of men have ever existed who have greatly varied in size from the ordinary proportions of our form, we need not allude to the fabulous stories of the giants and pygmies of antiquity, the former of whom are said to have made war against Jupiter, and the latter to have been not more than a foot high, and to have carried on war against the cranes which used to come and plunder them. Mention

is made of giants in several places in Scripture; before the flood, in the sixth chapter of *Genesis*, and more plainly after it, *Numb.* xiii.: but, as Dr. Derham observes, the antients vary as to the signification of the Hebrew word *nephilim* in Genesis. Some translate it by a word signifying 'violent men,' and think that instead of giants in stature, monsters of rapine and wickedness were intended to be represented; and Dr. Johnson says that the idea of a giant is always associated with something fierce, brutal, and wicked. With regard to the giants in *Numbers*, who are more particularly mentioned, it is probable that the fears of the spies magnified their dimensions. Races of giants are also alluded to by the Greek and Roman historians. The Germans are particularly noticed by Cæsar (*De Bel. Gall.*, lib. 1), and by Tacitus (*De Morib. German.*, c. 4) as being of large size. We have no data for determining their exact stature, but there is no proof that it exceeded that of the tallest of the present German races, many of whom, as the inhabitants of Saxony and the Tyrol, are very large men. The notion of the existence of giants in former times has, in many instances, been founded on the discovery of the bones of different large animals belonging to extinct species, which have been ascribed to human subjects of immoderate stature. (See the story in Herodotus, i. 68.) The bones of an elephant have even been figured and described by Buffon as remains of human giants, in the supplement to his classical work (tom. v.). The extravagance of such suppositions has been completely exposed by the accuracy of modern investigation.

Descending to more modern times, the people who have excited the most curiosity and given rise to the most conflicting statements are the Patagonians. The first navigators by whom they were observed represented them as being of colossal stature, but though more recent and accurate accounts describe them as being a very tall race of men, yet the highest does not much exceed seven feet. Captain Wallis measured several of them carefully, and found that the stature of the greater part was from 5 feet 10 inches to 6 feet. The height of the Patagonians was also measured with great accuracy by the Spanish officers in 1785 and 1786; they found the common height to be from 6½ to 7 feet, and the highest was 7 feet 1¼ inch.

It was once supposed that a nation of white dwarfs existed in the interior of Madagascar called Quimos or Kimos, with very long arms, but the report is now believed to be perfectly fabulous, and the only fact adduced in support of it was that the Count de Modave, the governor of the French settlement at Fort Dauphin, purchased a female slave of light colour about three feet and a half high, with long arms reaching to her knees. Blumenbach thinks that this was merely a malformed individual. From these and similar observations we may conclude that there is no truth in the existence of giants or dwarfs, except in peculiar individual instances; at any rate, as Dr. Pritchard observes (*History of Mankind*), 'every variety of stature which has been found to occur, as the general character of a whole race, is frequently surpassed by individual examples among the inhabitants of the same country.

There is no fixed law by which the human stature can invariably be determined, though there is an average standard from which the deviations either way are not very considerable. The human race varies mostly in height from four feet and a half to a little more than six feet, though men are occasionally met with of a much greater stature. Taking away the disposition to deal in the marvellous, we may probably assert that no man ever existed of the height of more than eight or nine feet. This may be supposed from what we see at present, and from the deviations which occur in the ordinary course of nature in animals. A skeleton was dug up some years ago on the site of a Roman camp near St. Albans beside an urn inscribed Marcus Antoninus. Mr. Cheselden, who has described it in the *Phil. Trans.*, No. 333, judged that it was 8 feet in height. Goliah, Og king of Basan, Maximinus the emperor, and others mentioned in sacred and profane history, were also probably very tall men, whose height has been magnified, but who were no bigger than some now occasionally met with. There are many authentic instances of men who have much exceeded the ordinary height, which have occurred in our own times: one of the king of Prussia's gigantic guards, a Swede, measured 8½ feet; and a yeoman of the Duke John Frederic, at Brunswick-Hanover, was of the same height. (Haller, *Element. Phy.*, lib. xxx., sec. 1.) Several Irishmen, measuring from 7 to 8 feet and upwards, have been exhibited in this country; the most celebrated, whose skeleton is in the museum of the College of Surgeons in London, was Charles Byrne, who went by the name of O'Brien: he died at the age of 22, in 1783, and measured 8 feet 4 inches. The skeleton is 8 feet in height. Many examples of dwarfs might also be mentioned. Buffon says that Bebe, the dwarf of Stanislaus, king of Poland, was 23 inches (French) high and well proportioned; he died at 23. But of numerous other instances on record most seem to have been rickety and diseased individuals. Thus in the skeleton, in the museum of the College of Surgeons, of Madlle. Crachami, the Sicilian dwarf, who died at the age of 10 years, and which is only 20 inches in height, the bones appear to have undergone hardly any change after birth. There seems to have been a complete arrest of development, the epiphyses of the bones remaining unossified.

We may remark that the ordinary size of man is particularly well adapted to his wants and uses, and we generally observe that those individuals who deviate greatly from the common standard, either one way or the other, are neither well proportioned nor healthy. The head in giants is commonly too small for the rest of the body, and in dwarfs too large.

Both giants and dwarfs have frequently offspring of similar stature to their own, so that a race of men might possibly arise of extraordinary smallness or gigantic size. Of the propagation of giants we have an experimental proof in a fact related by Dr. J. R. Forster (*Observations on a Voyage Round the World*). It is well known that the king of Prussia had a corps of gigantic guards, consisting of the tallest men who could be drawn together from all quarters. A regiment of these huge men was stationed during fifty years at Potsdam. 'A great number of the present inhabitants of that place,' says Forster, 'are of very large stature, which is more especially striking in the numerous gigantic figures of women. This certainly is owing to the connexions and intermarriages of those tall men with the females of that town.' Dr. Pritchard is of opinion that peculiarities of stature may in some measure be owing to peculiarities of climate. In his 'History of Mankind' (vol. ii.), he observes that 'there are many nations of very considerable stature in South America. The Patagonians are the most remarkable example, but nearly all the nations of this great country, though distinct from each other in language, manners, and descent, are taller and stouter than the average standard of the human species.' 'In Ireland men of uncommon stature are often seen, and even a gigantic form and stature occur there much more frequently than in this island: yet all the British isles derived their stock of inhabitants from the same sources. We can hardly avoid the conclusion that there must be some peculiarity in Ireland which gives rise to these phenomena.' Again: 'The tall, lank, gaunt, and otherwise remarkable figures of the Virginians and men of Carolina are strikingly different from those of the short, plump, round-faced farmers in England, who are of the same race.' Lawrence (*Lectures on Man*) thinks that the source of the deviations from the ordinary stature in man is entirely in the breed, and that they are quite independent of external influences. In endeavouring to account for the diversities of stature which occur we must make an observation which is equally applicable to differences of colour, features, and other particulars, in which individuals and particular races differ from each other, namely, that the law of resemblance between parents and offspring which preserves species, and maintains uniformity in the living part of creation, suffers occasional and rare exceptions; but that under certain circumstances an offspring is produced with new properties different from those of the progenitors.

GIANTS' CAUSEWAY, a remarkable columnar basaltic formation on the northern coast of the county of Antrim, in Ireland, situated about midway between the towns of Ballycastle and Coleraine.

The trap district with which this formation is connected occupies almost the whole of the county of Antrim, and a considerable portion of the eastern part of Londonderry, comprehending an area of about 800 square miles on both sides of the valley of the Bann. The surface rises gradually from the channel of this river till it attains a considerable elevation on each side, when it breaks down in precipitous escarpments, sloping abruptly to the primitive district of Londonderry on the west, and overhanging the coast on the east and north in a series of striking

elevations commencing near Belfast, and terminating west of the embouchure of the Bann. Throughout this area the basalt is found capping all the eminences, and constituting the general superstratum in beds of an average thickness of about 500 feet. Beneath the basalt occurs a series of secondary formations peculiar to this area, which has led to the supposition that they may have been elsewhere removed by some denuding force, 'to which, in this quarter alone, an effectual resistance was opposed by the firm and massive superstratum of basalt which covered and protected them.' (Rev. W. Conybeare, in *Trans. Geolog. Soc.*, vol. iii., p. 127.)

These formations, which are similar to those underlaid by the coal measures of the south and east of England, consist, in descending order, of thick beds of indurated chalk, the white limestone of Antrim, succeeded (unless where the series is broken, as it frequently is, by the superior stratum extending beyond the outgoings of the inferior, as at Fair-head, where the basalt rests immediately upon the coal-measures) by mulatto or green sandstone reposing on blue argillaceous limestone, which again rests on the red sandstone of the coal formation, which appears to underlie the greater part of the basaltic tract.

The mass of basalt is considerably thicker towards the northern extremity of the area, and it is here chiefly that the series of columnar formations occur. There are three distinct beds of such formations, the uppermost of which is perhaps traceable in the cliffs of the Cave hill over Belfast, and is distinctly observable at Fair-head, on the north-eastern extremity of the coast, where the mural precipice of greenstone is articulated into columns of enormous dimensions but rude structure, some of them measuring 250 feet in length by six feet on the side. The same formation appears occasionally to recur along the verge of the precipice which trends westward from hence to Dunseverick, at a short distance from which the two lower beds emerge from the sea, and, rising along the escarpment of the rock, form colonnades of the most striking appearance for a distance of nearly three miles, when the upper one is lost in the surrounding masses of basalt, while the lower stratum sinks again under water, its denuded extremity forming that particular group of columns known as the Giants' Causeway.

A section of the cliff at Bengore-head, immediately adjoining the Causeway, gives the following arrangement:—

	Feet.
1. Basalt, rudely columnar	60
2. Red ochre or bole	9
3. Basalt, irregularly prismatic	60
4. Columnar basalt	7
5. Intermediate, between bole and basalt	8
6. Coarsely columnar basalt	10
7. Columnar basalt, the upper range of pillars at Bengore-head	54
8. Irregular prismatic basalt. In this bed the wacke and wood coal of Port Noffer are situated	54
9. Columnar basalt, the stratum which forms the Causeway by its intersection with the plane of the sea	44
10. Bole or red ochre	22
11, 12, 13. Tabular basalt, divided by seams of bole	80
14, 15, 16. Tabular basalt, occasionally containing zeolite	80
	488

It is observable that the dimensions of the columns diminish and the perfection of their structure increases as the strata descend. Thus the most perfect arrangement is found in the lowest stratum, of which arrangement the Causeway affords the most perfect specimen. The upper part of the stratum being here denuded for a distance of about 300 yards, exhibits an irregular pavement formed of the tops of polygonal columns, so closely arranged that the blade of a knife can with difficulty be inserted in the interstices. The columns are chiefly hexagonal, but polygons of five, seven, and eight sides, are of frequent occurrence; and there is one instance of a triangular prism. These columns are divided into joints of unequal length; each joint is formed by the adjacent extremities being relatively convex and concave, an arrangement which is further secured by the overlapping of the external angles. These convexities and concavities are segments of spheres, the base of each of which occupies a circle inscribed in the polygon of the pillar; the intervals intercepted between the peripheries of these circles and the sides of the polygon are all in the plane perpendicular to the axis of the column. The stone is the most compact and homogeneous variety of basalt, and is more or less sonorous when struck with a hard substance. The entire mass of these columns, of which about thirty feet are exposed above the surrounding shingle at the highest point of their denudation, bears a strong resemblance to an artificial mole projecting from the base of the cliff into the sea.

It is probable that the columnar beds of which the exposed edges present these remarkable appearances along the coast underlie the capping of tabular basalt to a considerable distance inland, as columnar façades break out on the seaward slope of the entire line of elevations extending from Ballycastle to Bushmills, and indications of a columnar tendency have been observed in beds of tabular basalt as far inland as Glen Rovel, near Cushindall, and at the Cave-hill, near Belfast. Along the coast at Ushet-haven, Roanscarave, and Thivigh, are several smaller causeways nearly as perfect as the one described. The columnar strata of the islands of Rathlin and Staffa indicate the extent of the same formation northward and eastward.

The vicinity of the Giants' Causeway affords numerous appearances confirmatory of the opinion that the basalt when superinduced over the secondary strata was in a state of fusion from heat: such are the conversion of old red sandstone into hornstone, the conversion of clay-slate into flinty-slate, the conversion of coal into cinders, and in numerous instances the conversion of chalk into granular marble, all arising from the contact of trap dykes with the altered strata. At Kenbaan, near Ballinoy, the basalt is found inclosing detached masses of chalk, as well interspersed through trap dykes as in the mass of the formation. Similar instances occur near the Cave-hill.

Although this is the most important trap district in Ireland, yet basaltic formations are not altogether peculiar to it, columnar façades having been observed in the county of Limerick. (*Philosophical Transactions; Transactions of the Geological Society*, vol. iii.; *Guide to the Giants' Causeway*, Dublin, 1834.)

GIARDI'NI, FELICE, one of the greatest violinists of the last century, who contributed largely to an improved manner of performing in England, was born at Turin, in 1716, and entered as a chorister in the cathedral at Milan, where he received his elementary education in singing, on the harpsichord, and in composition, and at the same time studied the violin under Lorenzo Gomis, a favourite disciple of Corelli. At the age of seventeen he joined the orchestra of the Opera at Naples; then, making the usual tour of the Italian theatres, visited Germany, and at Berlin excited a *furore* by his performance on the instrument which he early adopted. Giardini, coming to our shores in 1750, immediately distinguished himself, and speedily was appointed to almost every situation of honour and profit that a great violinist could obtain in the British capital. In 1756, joining with the famous *cantatrice* Mingotti, he became manager of the King's Theatre, an office for which he was so little qualified that he soon abandoned it, having sustained a considerable loss by his inconsiderate undertaking. But, untaught by experience, he and his former partner, eight years afterwards, once more embarked in the same concern, and in two years were again compelled to retire from an enterprize so ruinous when not understood. He now pursued his profession as a leader, and also gave lessons in singing. In 1784 he went to Naples, where he became a guest of Sir W. Hamilton, the English minister and a very superior performer on the violin. In 1789 he returned to England, but was coldly received, and failed in establishing a burletta-opera at the little theatre in the Haymarket. In 1793 he took his burletta *troupe* to St. Petersburg, then to Moscow, but was as unsuccessful in Russia as in London. After experiencing many disappointments—the result of bad judgment, singular imprudence, defeated cunning, and habits not over scrupulous—he died at St. Petersburg, in a state of great poverty, in 1796. Giardini possessed much imagination and a fine taste. He composed, partly, three Italian Operas, and one entirely. His English oratorio, *Ruth*, continued to be performed many years; and his songs, 'Let not Age,' 'Tis not wealth' (in *Love in a Village*), with a few others, are still admired by the lovers of pure melody. Besides which he published many quintets, quartets, trios, &c., for violins, and also six harpsichord sonatas;

but his instrumental music is now forgotten, and the probability is that, being deficient in depth and vigour, it will never be revived.

GIBBON. (Zoology.) [HYLOBATES.]

GIBBON, EDWARD, was born at Putney, in the county of Surrey, on the 27th of April, 1737. He has given us in his 'Autobiography,' which was published after his death by Lord Sheffield, copious particulars concerning his life and writings. From his own account we learn that in childhood his health was very delicate, and that his early education was principally conducted by his aunt, Mrs. Porten. At the age of nine he was sent to a boarding-school at Kingston-upon-Thames, where he remained for two years, but made little progress, in consequence of the frequent interruptions of his studies by illness. The same cause prevented his attention to study at Westminster school, whither he was sent in 1749, and 'his riper age was left to acquire the beauties of the Latin and the rudiments of the Greek tongue.' After residing for a short time with the Rev. Philip Francis, the translator of Horace, he was removed in 1752 to Oxford, where he was matriculated as a gentleman commoner of Magdalen College in his fifteenth year. Though his frequent absence from school had prevented him from obtaining much knowledge of Latin and Greek, his love of reading had led him to peruse many historical and geographical works; and he arrived at Oxford, according to his own account, 'with a stock of erudition that might have puzzled a doctor, and a degree of ignorance of which a school-boy would have been ashamed.' His imperfect education was not improved during his residence at Oxford; his tutors he describes as easy men, who preferred receiving the fees to attending to the instruction of their pupils; and after leading a somewhat dissipated life for fourteen months, he was compelled to leave Oxford in consequence of having embraced the Roman Catholic faith. His conversion was effected by the perusal of Dr. Middleton's 'Free Inquiry into the miraculous Powers possessed by the Church in the early Ages,' in which he attempts to show that all the leading doctrines of the Roman Catholic church are supported by the miracles of the early fathers, and that therefore the doctrines of the Church of Rome must be true, or the miracles false. Gibbon's early education had taught him to revere the authority of these fathers; he was induced to read some works in favour of the Roman Catholic faith; and in 1753, he 'solemnly, though privately, abjured the errors of heresy.' With the object of reclaiming him to Protestantism, his father sent him to Lausanne in Switzerland, to reside with M. Pavillard, a Calvinist minister. The arguments of Pavillard and his own studies had the effect which his father desired: in the following year he professed his belief in the doctrines of the Protestant church, and, according to his own statement, 'suspended his religious inquiries, acquiescing with implicit belief in the tenets and mysteries which are adopted by the general consent of Catholics and Protestants.' He remained in Switzerland for five years, during which time he paid great attention to study, and assiduously endeavoured to remedy the defects of his early education.

During his residence at Lausanne, he had become perfectly acquainted with the French language, in which he composed his first work, entitled 'Essai sur l'Etude de la Littérature,' which was published in 1761. 'It was received with more favour on the Continent than in England, where it was little read and speedily forgotten.' His studies after his return to England were much interrupted by attention to his duties in the Hampshire militia, in which he was appointed captain; and the knowledge of military tactics, which he acquired in this service, was not, to use his own words, 'useless to the historian of the Roman Empire.' During his visit to Rome in 1764, 'as he sat musing amidst the ruins of the Capitol, while the bare-footed friars were singing vespers in the temple of Jupiter, the idea of writing the decline and fall of the city first started to his mind.' Many years however elapsed before he began the composition of the 'Decline and Fall.' On his return to England, he commenced a work on the Revolutions of Florence and Switzerland; and in conjunction with a Swiss friend of the name of Deyverdun, published in 1767 and 1768 two volumes of a work entitled 'Mémoires littéraires de la Grande Brétagne.' His next work, which appeared in 1770, was a 'Reply to Bishop Warburton's Interpretation of the Sixth Book of the Æneid.' In 1774 he was returned to parliament by the interest of Lord Eliot for the borough of Liskeard; and for eight sessions he steadily supported by his vote, though he never spoke, the ministry of Lord North, for which he was rewarded by being made one of the commissioners of trade and plantations, with a salary of 800*l.* a year. In the next parliament he sat for the borough of Lymington, but resigned his seat on the dissolution of Lord North's ministry, when he lost 'his convenient salary, after having enjoyed it about three years.' During the time in which he was a member of parliament, he published, in the French language, at the request of the ministry, a pamphlet entitled 'Mémoire Justificatif,' in reply to the French manifesto and in vindication of the justice of the British arms. In 1776 the first volume of the 'Decline and Fall of the Roman Empire' appeared in 4to., and was received by the public in the most favourable manner: 'the first impression was exhausted in a few days; a second and third edition were scarcely adequate to the demand.' The second and third volumes, which terminated the history of the fall of the Western Empire, were published in 1781.

In 1783 he left England, and retired to Lausanne, to reside permanently with his friend M. Deyverdun. From this time to 1787 he was engaged in the composition of the last three volumes of his great work, which appeared in 1788. He spent some time that year in England to superintend the publication, and again returned to Lausanne, where he remained till 1793, when the death of Lady Sheffield recalled him to his native country to console his friend. He died in London, on the 16th of January, 1794.

The 'Decline and Fall of the Roman Empire' comprises the history of the world for nearly thirteen centuries, from the reign of the Antonines to the taking of Constantinople by the Turks; for the author does not confine himself to the history of the princes that reigned at Rome and Constantinople, but gives an account of all the various nations of the west and east which at any period influenced the destinies of the Roman empire. In the prosecution of this design it was impossible for the historian to neglect the history of the Christian church, which he properly considered as 'a very essential part of the history of the Roman empire.' Gibbon accordingly, in the course of his work, entered fully into the history of the church, and in the first volume devoted two chapters to an account of the early progress and extension of Christianity. In relating the causes that occasioned the spread of Christianity, he was supposed to have sought to undermine the divine authority of system; and numerous works were published in opposition to his opinions, to none of which did he make any reply 'till Mr. Davis presumed to attack not the faith, but the fidelity of the historian;' when he published his 'Vindication of the Fifteenth and Sixteenth Chapters of his History.' Gibbon's Sketch of Ecclesiastical History is perhaps the best work on the subject in our language; but it must at the same time be allowed that he writes rather as an advocate than as an historian, and though he seldom if ever wilfully perverts facts, yet he seizes every opportunity of casting ridicule upon the faith which he disbelieved.

The principal fault of Gibbon's history is owing to the extent and variety of the subject-matter. He included in his plan the history of so many nations that no single individual could do justice to every particular. The reading of Gibbon was very extensive, but yet not sufficiently extensive to give an accurate history of the world for thirteen centuries. His knowledge of Oriental history is often vague and unsatisfactory, and his acquaintance with the Byzantine historians is said by those who have studied the subject to be superficial. But, with all its defects, the 'Decline and Fall' was a great accession to literature; it connects antient and modern history, and contains information on many subjects which historians generally neglect and sometimes unsuccessfully attempt. Thus, in the 44th chapter, he gives an historical account of the Roman law, which is perhaps one of the best introductions to its study that we possess, and was considered by a celebrated foreign lawyer, Professor Hugo, to be worthy of a translation. Hugo published it at Göttingen, in 1789, under the title of 'Gibbon's Historische Uebersicht des Römischen Rechts.' The 'Decline and Fall' has been translated into almost all the European languages. The last edition of the French translation contains notes on the history of Christianity, by M. Guizot; and in a biography of Gibbon, by the same writer, in the 'Biographie Universelle,' he has expressed his opinion of the chief merits and defects of the 'Decline and Fall.'

The 'Decline and Fall' was also published in 12 vols. 8vo., London, and has since been frequently reprinted. His 'Miscellaneous Works, with memoirs of his life and writings composed by himself,' were published by Lord Sheffield in 2 vols. 4to., 1796; to which a third volume was added in 1815. The 'Miscellaneous Works' were reprinted in the same year in 5 vols. 8vo. This collection contains a republication of some of the works which have been already mentioned; and in addition to these, a large 'Collection of Letters written by or to Mr. Gibbon;' 'Abstracts of the Books he read, with Reflections;' 'Extracts from his Journal;' 'Outlines of the History of the World;' 'A Dissertation on the Subject of *L'Homme au Masque de Fer*;' 'Antiquities of the House of Brunswick;' 'Mémoire sur la Monarchie des Medes;' 'Nomina Gentesque Antiquæ Italiæ,' 'Remarks on Blackstone's Commentaries;' 'On the Position of the Meridional Line, and the supposed Circumnavigation of Africa by the Antients,' and other pieces of less importance.

GIBBONS, ORLANDO, who was not only 'one of the rarest musicians of his time,' as Anthony Wood styles him, but one of the finest geniuses that ever lived, was born at Cambridge in 1583. At the age of twenty-one he became organist of the Chapel-Royal. In 1622 he was honoured, at Oxford, with the degree of doctor, on the recommendation of his friend Camden, the learned antiquary. In 1625, attending officially the ceremonial of the marriage of Charles I., for which occasion he composed the music, he took the small-pox, and died on the Whit-Sunday following. He was buried in Canterbury Cathedral, where a monument, erected to his memory by his wife, is one of the objects that attracts the notice of visitors to that noble structure. This consists of a bust of Gibbons, over which is a shield containing his arms, and below it a tablet with a highly and justly laudatory inscription in Latin. The whole is simple but elegant, and a noble tribute of conjugal affection. An engraving of this is given by Dart, in his 'History of Canterbury Cathedral.'

Dr. Gibbons left a son, Christopher, who at the restoration, besides being appointed principal organist to the king, and to Westminster Abbey, was created doctor in music by the university of Oxford, in consequence of a letter written by Charles II. himself, which is inserted in the *Fasti Oxon.* He was celebrated for his organ-playing, and is said to have instructed Dr. Blow on this instrument. Orlando had also two brothers, Edward, organist of Bristol, and Ellis, organist of Salisbury. The former was sworn in a gentleman of the Chapel-Royal in 1604, and was master to Matt. Lock. During the civil wars he assisted Charles I. with the sum of 1000*l.*, for which he was afterwards deprived of a considerable estate, and, with his three grand-children, thrust out of his house, at a very advanced age. In the *Triumphs of Oriana* are two madrigals by Ellis Gibbons. 'Burney,' it is observed by the biographer of Gibbons in the *Harmonicon*, 'does justice to the sacred works of Gibbons, which, he says, "are still fresh and in constant use." His service in F is indeed above all praise for novelty, and for richness and purity of harmony. His three anthems, "Hosanna, to the son of David," "Almighty and everlasting God!" and "O clap your hands together," are masterpieces of the most ingenious and scientific writing in fugue that musical skill ever brought forth. But next to his service, we honestly avow our preference for his madrigals: "Dainty sweet bird," and "O! that the learned poets," are far above most other things of the kind; and "The silver swan" is even superior to both of these,—superior, not in elaborate contrivance, for it is comparatively simple, but in effect—the great and only true touchstone of art. Dr. Burney, who has taken very unfair advantage of an expression in the title-page to Gibbons's madrigals, wherein it is said that they are "apt for viols," has criticised them as instrumental pieces, and declared them to be "utterly contemptible." Performed as quintets for stringed instruments, we certainly should not apply any disparaging term to them even in the present day; but when they were written, so little music was printed for violins, &c., that vocal compositions were very commonly pressed into the service of instrumental performers; just as within the last forty or fifty years, songs of all kinds were regularly published with an arrangement for the flute.' (*Harmonicon*, x. 192.)

GIBBONS, GRINLING, an artist celebrated for the extraordinary taste and delicacy of execution he displayed in wood-carving, is supposed to have been of Dutch origin, though a native of London, where he was born in Spur Alley, Strand. Having been recommended by Evelyn to Charles II., the king bestowed upon him a place in the Board of Works, and employed him in the chapel of Windsor, where he executed much of the ornamental carving, consisting of such emblematic objects as doves, pelicans, palm-branches, &c. For the choir of St. Paul's he likewise did much of the foliage and festoons belonging to the stall-work, and those in lime-tree which decorate the side aisles of the choir. There is a great deal of his work at Chatsworth—mere ornament indeed, such as foliage, flowers, feathers, &c., but finished with such exceeding delicacy and truth, that the workmanship not only confers value on the material, but also on the subject. Occasionally he exerted his skill on subjects altogether trivial in themselves, and merely curiosities in art; for instance, feathers and pens that might be mistaken for real ones; and such productions as the point-lace cravat wrought up in wood, which he presented to the duke of Devonshire on completing his labours at Chatsworth. At Southwick, in Hants, he did the embellishments of an entire gallery; and also a room at Petworth, which last has generally been considered one of his chief performances. All these works were merely ornamental, and analogous to what is termed still-life in painting; yet that Gibbons had talents for those of a higher character is proved by his statue of James II., behind the Banqueting House, Whitehall. Yet after all it was in his own peculiar walk that he was distinguished, and he deserves in some degree to be considered as the English Cellini. He died August 3, 1721.

GIBBOUS, convex on both sides; a term particularly applied to the moon when more than half grown.

GIBBS, JAMES, an architect of considerable eminence in his day, and who has since maintained a high rank among English architects, was born about the year 1674 at Aberdeen, where he was educated and took the degree of master of arts at the Marischal college. By the loss of both his parents he was left to his own direction. In his twentieth year he visited Holland, where he entered into the employment of an architect, with whom he continued till 1700, when, by the advice and aided by the assistance of his countryman, the earl of Mar, who had himself a taste for architecture, he proceeded to Italy in order to improve himself in his art. Diligence he did not lack, and therefore as far as relates to making studies, sketches, and memoranda, he may be said to have employed his time successfully, yet that he wanted discrimination, and the ability to improve upon his models is too plainly attested by nearly all his works. After spending ten years in Italy, during several of which he studied at Rome under an architect named Garroli, he returned to England and found his patron, the earl of Mar, in the ministry. By that nobleman he was recommended to the commissioners for building the fifty new churches, and this circumstance opened to him those opportunities which, in the opinion of his admirers, he employed so worthily. Another ten years however elapsed before he was called upon to make trial of his ability in any of the metropolitan churches, for his first one, namely St. Martin's, was not commenced till 1720-21. In the interim he erected what is called the new building at King's College, Cambridge, a design which, if not much distinguished by originality or any other excellence, exhibits comparatively few of Gibbs's faults: and if it gains little by being placed close beside that exquisite architectural gem, the Chapel, neither does it lose much, because there are no points of comparison between the two buildings. If this work is little spoken of, St. Martin's, which was completed in 1726, has been liberally extolled not only as its author's *chef d'œuvre*, but as a first-rate piece of architecture, but chiefly it would seem as an application of a portico upon a satisfactory scale and at a time when such a feature was by no means so common as it has since become. Certain it is that, in regard to the exterior at least, few have extended their eulogium to any other part of it; yet for the portico he found a model ready prepared to his hands requiring only to be adapted to a specific purpose, and if, in selecting it, he paid a tribute to the classical grandeur of the original, he seems to have looked at it only with the eye of a copyist.

Every other feature is at variance with the portico and the order: lumpishly heavy and uncouth, without even anything of that picturesque richness which sometimes results from exaggerated details and other subordinate forms. The windows are fitter for a prison than a church; and some of them being unfortunately allowed to obtrude themselves

within the portico, they and the doors (which are similarly patched over with unmeaning rustic blocks) quite dispel the charm that would be produced by the columns alone. The interior is not at all better: there we behold columns cut by deep galleries which have no apparent support, and whose capitals are surmounted by blocks representing so many broken bits of entablature, from which spring the arches of the ceiling: and this latter is ornamented more profusely than elegantly, or than is in keeping with the rest. For this church Gibbs submitted two other designs, which he himself, he tells us, considered preferable to the one executed. They are both given in the folio volume of designs which he published in 1728, and by which he is said to have made nearly 2,000*l.*, no inconsiderable sum at that time, especially for a work of such a nature. Much as those differ from the present building, the body of the church in both of them being circular in its plan (about 95 feet in diameter), so far from displaying invention, they show, even in the way of alteration, very little more than was absolutely called for by such change of the general form. The taste manifested in them partakes far more of Holland, the country where Gibbs made his first sojourn abroad, than of classical Rome.

The same remark will apply to his next work, the church of St. Mary in the Strand, an exceedingly heterogeneous composition, with nothing in its ensemble to reconcile us to its individual solecisms; and yet, though this building is abandoned to censure even by the architect's professed admirers, it may be questioned whether upon the whole it be not less offensive to sound taste than St. Martin's: for it is at least more consistent in its whims, and is not, like that, an ugly appendage to what would else be a noble portico.

In the church of All Saints at Derby, where he added a new body to the old Gothic tower, he did little more than repeat with some slight variation what he had done at St. Martin's. He also built Marylebone chapel, the upper part of the steeple of St. Clement's Danes, and St. Bartholomew's Hospital. His best work is the Radcliffe library at Oxford, a rotunda about 140 feet in diameter externally, covered by a dome 105 in diameter; for, notwithstanding that the niches and some other parts are the reverse of elegant, there is some approach to simplicity in the general mass and its contours, and something of grandeur in the interior. To this library, which was begun in 1737 and completed in about ten years, and the designs for which he published in a separate volume, containing 23 plates, Gibbs made a valuable bequest of books. He died August 5th, 1754, and having never been married, left his property, amounting to about 15,000*l.*, to different individuals and public charities, not forgetting the son of his first patron, the earl of Mar, to whom he bequeathed a legacy of 1000*l.*, besides an estate worth about 280*l.* a year.

Neither Walpole nor Dallaway speaks at all favourably of Gibbs's talents as an architect; the former even scornfully, yet not otherwise unjustly than because he expresses his opinion too summarily, without adducing any proofs in support of it. His works certainly do not display either grace or happiness of invention. They have for the most part all the heaviness of Vanbrugh's designs, without their other redeeming qualities. They discover neither an innate nor acquired perception of beauty in forms and of harmony in their combination. Nevertheless, in respect of what he almost accidentally borrowed on one occasion, he is generally spoken of, not as a judicious copier, but as an artist of original mind and unquestionable genius.

GIBBSITE, a mineral which occurs massive, in irregular stalactitical and tuberculated masses. Its structure is fibrous, radiating. Its colour is white, with a slight shade of green or grey; streak white: it is slightly translucent, lustre feeble. Its specific gravity is 2·09 to 2·4. Rather harder than calcareous spar; easily reduced to powder.

Before the blow-pipe it whitens, but is infusible; does not effervesce with acids, but loses water by heat.

It is found at Richmond, in Massachusetts, in a neglected iron mine.

It consists of

GIBRALTAR, a town and fortified rock in Andalusia, the most southern province of Spain. The rock, which is connected with the continent by an isthmus of low sand, and almost wholly surrounded by the waters of the Mediterranean, forms a promontory three miles in length from north to south. The width is irregular, but the entire circumference is about seven miles. Towards the south it terminates in a point called Europa Point, which is in 36° 2′ 30″ N. lat., and 5° 15′ 12″ W. long. This rock, under the name of Calpe, and Mount Abyla (now called Ceuta), opposite to it on the African coast, were called by the antients the Pillars of Hercules, and in very early ages were regarded by the people dwelling to the east of them as the western boundary of the world. (As to Calpe, see Strabo, *Casaub.*, pp. 139, 156, &c.) In the early part of the eighth century an army of Saracens under the command of Tarif, or Tarek, from the coast of Africa, landed near to Gibraltar with the intention of dethroning Roderic, king of Spain. The Saracens erected a castle on the shoulder of the rock, and called the rock itself Gibel-Tarif (the mountain of Tarif), whence its present name of Gibraltar is supposed to be derived. The ruins of this castle may still be seen. The African Moors continued in possession of Gibraltar till the beginning of the fourteenth century, when it was recovered from them by Ferdinand IV., king of Castile and Leon. It subsequently fell into the hands of the king of Granada, from whom it was taken in 1462 by the Christians under Henry IV. king of Castile, who gave it the arms it still bears, viz. a castle with a key hanging to the gate, alluding to its being the key to the Mediterranean. From this time to the end of the sixteenth century Gibraltar remained in the hands of the Spaniards, by whom the fortifications were so far increased and modernized that the place was looked upon as impregnable until taken by an English and Dutch fleet under Sir George Rooke and the prince of Hesse Darmstadt, on the 24th of July, 1704. During the nine following years several unsuccessful attempts were made to recover the fortress by force or stratagem, in which the loss of the assailants was very great. In 1713 the possession of Gibraltar was confirmed to the English by the peace of Utrecht. In 1727 it was again attacked by the Spaniards with an army of 20,000 men. The siege continued for several months, and was terminated by the general peace on the 12th of May. The last and most memorable of all the sieges of Gibraltar was commenced in 1779, and did not terminate till the 2nd of February, 1783. For a detailed account of this siege the reader is referred to the interesting work of Captain John Drinkwater and M. Bourgoing, and also to the 'Life of General George Augustus Elliot (afterwards lord Heathfield), the governor and brave defender of Gibraltar, whose conduct throughout forms one great example of moral virtue and military talent. The grand attack took place on the 13th of September, 1782. On the land side, besides stupendous batteries mounting 200 pieces of heavy ordnance, there was an army of 40,000 men, commanded by a victorious general, the Duc de Crillon, and animated by the immediate presence of two princes of the crown of France. In the bay lay the combined fleets of France and Spain, consisting of 47 sail of the line, numerous frigates and smaller armed vessels, besides ten battering ships, which alone had cost upwards of 500,000*l.* Four hundred pieces of the heaviest artillery (reckoning both sides) were playing at once. The battering ships were found to be of so formidable a construction that the heaviest shells rebounded from them. Eventually however two of them were destroyed by the incessant discharge of red-hot shot from the garrison, and the remaining eight were burnt by the enemy to prevent them from falling into the hands of the besieged. The remainder of the enemy's squadron also suffered considerably; but notwithstanding their failure the assailants kept up a less vivid fire for more than two months, and the siege did not finally terminate till the 2nd of February, 1783, when it was announced that the preliminaries of a general peace had been signed. The expenditure of the garrison exceeded 8300 rounds (more than half of which were hot balls), and 716 barrels of powder. That of the enemy could not be ascertained, but their loss, including prisoners, was estimated at 2000, while that of the garrison only amounted to 16 killed and 68 wounded. While the floating batteries were on fire a detachment of British marines under Brigadier Curtis, was humanely and successfully employed in rescuing numbers of the enemy

from their burning citadels. The failure of this memorable attempt to wrest Gibraltar from the possession of England has been partly attributed to a want of co-operation among the enemy's forces, but the principal cause was, no doubt, the gallant defence made by General Elliot and his brave garrison, notwithstanding their frequent and extreme suffering from want of provisions and from the prevalence of disease.

The rock consists principally of a grey compact marble. It abounds with caves, the most remarkable of which is St. Michael's, on the south-west side. The entrance to this cave is 1000 feet above the sea-level, and leads to a spacious hall, apparently supported by massive stalactites. Beneath this is a succession of descending caves beautifully picturesque, but of difficult access. The impurity of the atmosphere has hitherto prevented their being explored to a greater depth than 500 feet below the entrance, but when the writer visited this spot a few months since he was assured by the person who attended him, that at the above depth the waves of the Mediterranean might occasionally be heard beating into the caves beneath. In the perpendicular fissures of the rock bones of various animals, including human bones, have frequently been discovered. The natural productions of Gibraltar are wild rabbits, woodcocks, teal, and partridges; there are also large numbers of monkeys, of a dark fawn-colour, and without tails. The climate is temperate during the greater part of the year, and even in the summer months the excessive heat is allayed by a refreshing sea breeze that sets in during the forenoon and continues till sun-set. The temperature in winter is considerably higher than in the neighbouring country, so that the snow, which falls but seldom, soon disappears, while it continue for many weeks on the mountains of Africa and the Sierra Morena. On whichever side the rock is approached it has a barren and forbidding appearance. From the ship's deck not a spot of verdure can be seen, and yet it is by no means destitute of vegetation, for besides acacias, fig and orange trees, there is a great variety of odoriferous plants. The east and north sides of the rock are, from their steepness, wholly inaccessible. Towards the south it is also very precipitous, but on the west side, where the town is built, it gradually declines towards the bay, where the strength of the fortifications is such that the fortress appears to be impregnable. Besides the fortifications of which we have just spoken, there are two excavations, wrought with extreme labour, in the solid rock, called galleries, which extend from two to three miles in length, and are of sufficient width for carriages. Along these galleries, at intervals of every twelve yards, are port-holes bearing upon the neutral ground and bay. The Spanish lines, which extend across the isthmus, are defended by two forts, the principal of which is called St Philip. The space between these lines and the foot of the rock is called the neutral ground, and it is here that the lazaretto is situated. The town is built on a bed of red sand, near the foot of the north-west side of the hill. It is paved and lighted, and consists chiefly of one street, extending about a mile in length from South-port to Water-port.

The principal buildings are the governor's and lieutenant governor's houses, the Admiralty (formerly a monastery of White Friars), the barracks, victualling-office and store-house, the Spanish church, and Jews' synagogue. Towards Europa Point are the South barracks and navy hospitals, both fine buildings, pleasantly situated, and well adapted to the purposes for which they were built. The water for the supply of the town and garrison is collected during the rainy season, and conveyed to the garrison by means of an aqueduct erected by the Spaniards. The roofs of the houses are so constructed as to receive the falling rain, and to conduct it to a tank beneath, with which every house is provided. The nearest spring is on the neutral ground, and even there the water is brackish. The provisions are principally derived from Africa. The town can neither be called clean nor neat. The houses are built in the English style, without any regard to their ventilation, so essential to the health of the inhabitants, and so studiously observed in all Spanish towns. The inns are mean, and exceedingly dear.

There is a charter according to which all criminal causes are to be determined according to the laws of England. Disputes between debtor and creditor are referred to the judge-advocate from whose award an appeal may be made to the governor, whose decision is final, unless the sum exceed 300*l.*, in which case a further appeal may be made to the privy council at home. Every precaution is taken to prevent the increase of new residents. Foreigners are allowed permission to remain during specified periods on giving the required security. The trade of Gibraltar has much declined within the last half century. In 1831 the declared value of British produce and manufactures exported to this port was 367,285*l.*, and the official value of foreign and colonial produce for the same year was 121,342*l.* Accounts are kept in current dollars of eight reals each; the hard dollar (peço duro) being equal to twelve current reals. The weights and measures are those of England, with the addition of the aroba of 25 lbs.

Gibraltar being a free port, subject to few duties and few restrictions, is a convenient entrepôt for merchandize destined for the neighbouring provinces of Spain and Africa. According to the return made to parliament in 1822, the average annual revenue collected in the town during the two preceding years was nearly 24,000*l.*, which was about sufficient to defray the public civil expenditure of the place: and according to the minutes of evidence taken in 1834 before a committee on colonial military establishments, it appears that the annual expense incurred by Great Britain on account of the garrison in time of peace is 172,439*l.* By the same document it appears that the strength of the garrison in 1834 was 3354 of all arms, and the population of the town is estimated at 16,000 to 17,000, of which number more than 8000 are foreigners. The garrison contains a good library, to which each officer subscribes four dollars annually.

GIBRALTAR, THE BAY OF, formed by the headlands of Cabrita and Europa Points, is commodious, and secure from all the more dangerous winds. The greatest width from east to west is five miles: its greatest length from north to south, reckoning from Rocadillo to Cabrita Point, is about eight miles, and its depth in the centre exceeds 100 fathoms. The tide rises about four feet, and the variation of the needle is 22° 31′. It supplies the garrison with abundance of fish. The shipping is protected by two moles, constructed at great expense, and extending into the bay to the respective distances of 700 and 1100 feet. On the western side is situated the pretty town of Algeziras, which the Spaniards have fortified since Gibraltar has been in the possession of England. A little to the south-west of this town is an island (Isla Verde), which adds to the general beauty of the bay.

GIBRALTAR, THE STRAITS OF, antiently called the Straits of Hercules, are about 12 leagues in extent from Cape Spartel to Ceuta Point, on the African coast, and from Cape Trafalgar to Europa Point, on the coast of Spain. Their width at the western extremity is about eight leagues, but at the eastern extremity it does not exceed five. A strong current is constantly running from the Atlantic into the Mediterranean, which renders the passage of sailing-vessels bound to the westward extremely precarious, and only practicable by means of a brisk Levant wind. Dr. Halley was of opinion that the daily evaporation of the Mediterranean was sufficient to account for the consumption of this constant influx of water, but it should be mentioned that there are two counter-currents along the shores of Spain and Africa respectively, although their breadth and rapidity are small compared with the principal current.

GIBSON, Dr. EDMUND, bishop of London, born 1669, died 1748. Bishop Gibson was the son of Edmund and Jane Gibson, of the parish of Bampton, in Westmorland, a district which has produced more persons who have emerged from that obscurity in which their parents had lived, and become eminent in divers walks of life, than perhaps any other in the kingdom. To this it is supposed that the grammar-schools established in those parts of the kingdom have much contributed, but it is more probable that it has been active and industrious grammar-school masters. He pursued his studies with great vigour, first in his own county, and then in the university of Oxford, of which perhaps the best proof that could be required is given by his having at the age of twenty-two prepared an edition of the 'Saxon Chronicle,' with a translation into Latin, and suit-

able indexes and other assistances in the use of that valuable historical remain. The work was printed at Oxford in 1692, in a 4to. volume. This 'Chronicle,' which is highly esteemed by historians, is the work of different hands, and contains an account of English affairs to the year 1154, in which are several things not found in the corresponding chronicles written in the Latin language. At that early period of his life he projected and accomplished an enlarged edition of the English translation of Camden's 'Britannia,' and he had already acquired fame and interest sufficient to engage in his assistance many antiquaries in different parts of the kingdom, by whose contributions the work was enriched, and came forth from the hands of Dr. Gibson a great improvement on the old English edition of Philemon Holland. This work appeared in 2 vols. fol., in 1695. It appeared again in an enlarged form in 1722, and again in 1772. Richard Gough, an eminent topographical scholar, enlarged it still more, and it appeared in 3 vols. fol., in 1789. It was still further enlarged to 4 vols. fol. in 1806. But though works of this kind have their use, it is to be regretted that Bishop Gibson should have preferred making additions to a former work instead of undertaking a description of the British Islands on a plan of his own, embracing many particular heads of information which were excluded from the plan which Camden himself adopted. This would have been an achievement more worthy of himself, and more just to the memory of his illustrious predecessor, whose singularly beautiful and learned work is absolutely lost in the mass of matter which has been heaped upon it. [CAMDEN.] Another early production of Dr. Gibson was an edition of some historical remains of an eminent antiquary of the seventeenth century, Sir Henry Spelman, which was published at Oxford in 1698, under the title 'Reliquiæ Spelmannianæ.' These works show the original predisposition of bishop Gibson's mind: but he did not at that period of his life confine himself to historical literature, for in 1693 he produced an edition of 'Quintilian,' which is highly esteemed.

The proof of industry and learning which these works afforded introduced him to the notice and favour of Tenison, who, in 1694, succeeded Tillotson as archbishop of Canterbury. He was made domestic chaplain to the archbishop, and rector of the parish of Lambeth. He was also made archdeacon of Surrey.

In the reigns of king William and queen Anne there was a warm controversy concerning the nature and authority of the convocation of the clergy. In this controversy Dr. Gibson took a very active part, defending the power of that assembly, in which his historical knowledge was made to bear powerfully on the question. This led to the publication which is regarded as his great work, the 'Codex Juris Ecclesiastici Anglicani,' 2 vols. fol., 1713, in which he has collected the statutes, constitutions, canons, rubrics, and articles of the Church of England, and digested them methodically under proper heads, with suitable commentaries, prefaces, and appendices, forming together a work which is indispensable to the studies of those who desire to understand thoroughly the history of the English church. It was reprinted at Oxford in 1761.

In 1715 he was promoted to the bishopric of Lincoln; and in 1723 translated to London. Wake, the archbishop of Canterbury, was at that time in an infirm state of health, and so continued for some years, during which period the bishop of London was the person chiefly consulted by the court in affairs belonging to the church.

Bishop Gibson was ever a strenuous defender of the rights of the church, considered as a political community; but he was of what is called the liberal school in respect of doctrines, and he warmly approved of the liberty which the law had granted in his time to persons not conforming to the church to meet together publicly for social worship in whatever way and on whatever principles they might themselves approve. He published a large collection of treatises which had been written by divines in the English church against popery, forming three folio volumes, printed in 1738. His 'Pastoral Letters' is the last of his works we have occasion to mention, in which he combats at once unbelief and enthusiasm.

In his private relations the bishop was greatly beloved and respected. He closed a life, extended to his eightieth year, almost unequalled for labour in the annals of literary exertion, in 1748, and was buried at Fulham, with many of his predecessors

GIEN. [LOIRET.]

GIESECKITE, a mineral which occurs in hexagonal prisms. Structure granular, and hence it has been supposed that the crystals are pseudomorphous; fracture uneven: hardness 2·5 to 3·5; colour externally brownish, and internally greenish; opaque, or feebly translucent at the edges; specific gravity 2·832.

Before the blow-pipe it is very refractory.

It was brought from Greenland by Sir C. Giesecke.

Analysis by Stromeyer:—

Silica	49·24
Alumina	33·82
Potash	6·20
Magnesia	1·20
Oxide of iron	3·35
Oxide of manganese	1·15
Water	4·80
	99·76

GIESSEN, a bailiwick of the Grand-duchy of Hesse, ntaining two towns, two market-villages, thirty-five villages and hamlets. Giessen, the chief town of this bailiwick, as well as of the province of Upper Hesse, is built on the banks of the Lahn and Wieseck, which form a junction at this spot in the centre of a beautiful country. It is about thirty-three miles to the north of Frankfort on the Main, and at an elevation of about 430 feet above the level of the sea: in 50° 34′ N. lat. and 8° 40′ E. long. The town is old and ill-built, with the exception of three or four broad streets, is surrounded by the two rivers on all sides, and contains about 770 houses and 7300 inhabitants: their numbers were 4046 in 1806, and 5500 in 1817. The fortifications have been razed and their site converted into shrubberies and promenades. It has three squares, an old castle, an arsenal, three churches, university buildings, a hospital, house of correction, &c. The university of Giessen, which is the only one in the grand-duchy, was established in the year 1607, and is attended by about 400 students. The buildings appropriated to its use are handsome, and contain lecture-rooms, a library, clinical establishment, chemical laboratory, museums of natural history and the arts and sciences, &c Connected with it are the academy for forest economy, gallery of antiques, an obstetric institute and school, a botanic garden, an observatory, schools for educating teachers, and the Senkenberg library, which possesses several scarce MSS. Giessen is the seat of government for the province of Upper Hesse. It is not a place of much commercial industry, and the manufactures are confined to woollen yarn spinning, stocking-knitting, and cotton-weaving, on a small scale.

GIFFORD, WILLIAM, a political writer and critic of no small influence in his life-time, was born at Ashburton, in Devonshire, in April, 1757. He was descended of a family once of some name in the county: but the indiscretion of his ancestors gradually wasted the property, and the early death of both parents left him, at the age of thirteen, penniless, homeless, and friendless. His godfather, on a claim of debt, took possession of their scanty effects, clogged with the charge of the orphan. From him Gifford received little kindness. He spent some time as cabin-boy on board a little coasting-vessel: at the age of fifteen, he was apprenticed to a shoemaker at Ashburton. In spite of a neglected education, his talents showed themselves in a strong thirst for knowledge. Mathematics at first were his favourite study; and he relates that, in the want of paper, he used to hammer scraps of leather smooth, and work his problems on them with a blunt awl. His master, finding his services worth nothing, used harsh means to wean him from his literary tastes; and Gifford, hating his business, sunk into a sort of savage melancholy. From this state he was withdrawn by the active kindness of Mr. Cookesley, a surgeon of Ashburton, who, having become acquainted with his first rude attempts at poetry, and with his sad story, conceived a strong regard for him, and taxed his own purse and interest so effectually as to raise the means of freeing him from his indentures, placing him at school, and sending him, after two well spent years, to Exeter College, Oxford. He appears to have commenced residence about the age of twenty-two or twenty-three. Not long after he sustained a most severe affliction in the untimely death of Mr. Cookesley. But a more efficient and equally sincere friend was soon raised up in the person of Earl Grosvenor, who, in consequence of the casual perusal

of a letter, became interested in Gifford's character and fortunes, gave him a home under his own roof, in or about the year 1782, and in great measure entrusted to him the charge of his son, the present Marquis of Westminster, with whom, though widely differing in politics, Gifford maintained through life an intimate and unvarying friendship. It appears that he did not remain long enough at Oxford to take a degree. Here ends the romantic part of his history; the rest of his life is simply the chronicle of his works.

The first of these, in order of publication, was the 'Baviad,' a paraphrastic imitation of the First Satire of Persius, 1791, a strong stern attack on what was called the Della Cruscan style of poetry, which for its utter folly and emptiness deserved no quarter. A short account of its rise is given in the preface to the 'Baviad,' which put an end to this affectation. Less successful, though not less powerful in execution, was the 'Mæviad,' a similar satire directed against the puerilities and extravagance of the modern drama. The peculiar talent displayed in these two pieces indicated the author's fitness to undertake a translation of Juvenal, a task which he had commenced even before his residence at Oxford, and had never altogether abandoned, though the untimely death of Mr. Cookesley, to whose care the revision of these early efforts was entrusted, had caused it to be laid aside for a time in disgust. The translation of Juvenal was published in 1802, with a short autobiography prefixed, which for its unaffected candour and manliness is worthy of all praise. The diction and versification of the translation are powerful and flowing; and the honest anger, the fearless crushing invective, the stinging sarcasm of the Latin poet, are rendered in so congenial a spirit as to convey to the English reader a satisfactory idea of the original. Some of his minor pieces are tender and beautiful, and indicate that he might have succeeded as a poet in a softer strain. He had paid much attention to old English poetry, the fruit of which appeared in his editions of Massinger, 4 vols. 8vo., 1805; Ben Jonson, 9 vols., 1816; Ford, 2 vols., 1827; and Shirley, 6 vols., 1833: the two last were posthumous. He is said to have meditated an edition of Shakspeare.

In that time of strife, Mr. Gifford entered with his whole heart into the views of the Antigallican party. He was a devoted admirer, and, in later years, an intimate friend, of Mr. Pitt. In 1798 his known ability recommended him to be editor of the 'Antijacobin,' [CANNING, GEORGE], a connection which introduced him to the most brilliant circles of political and literary men, such as Pitt, Canning, Lord Liverpool, the Marquis of Wellesley, Frere, George Ellis, and others. In 1809 he resumed the office of a political partizan upon a more extended scale, as editor of the 'Quarterly Review.' Of the establishment of this celebrated journal, avowedly as a political machine, and as a counterpoise to the Edinburgh, some very interesting notices will be found in Lockhart's 'Life of Scott,' vol. ii., ch. 6 and 7. The selection of Mr. Gifford for its conductor was most happy. A great stock of knowledge, a powerful and ready pen, a strong talent, unchecked by fear or pity, for satire, a full undoubting belief in his political creed, fitted him admirably for his employment; and the success of the Review was most brilliant. His salary was at first 200*l.*; it was gradually increased to 900*l.* per annum. It is asserted that his political partizanship was disinterested, and that he very rarely either asked or received a favour from ministers. He was himself appointed first to the paymastership of the Band of Gentlemen Pensioners, and secondly to a commissionership of the lottery. He was generous in pecuniary matters, and in private life and conversation is reported to have been unassuming and courteous. He appears to have had the power of feeling and inspiring strong friendships. His gratitude to Mr. Cookesley was ardent, and ended only with his life; indeed he made one of that gentleman's family the principal inheritor of his fortune. During the latter years of his life he suffered greatly from asthma, and withdrew from general society. He gave up the editorship of the 'Quarterly Review' two years before his death, which took place December 31, 1826, at his house in James Street, Buckingham Gate. A paper containing an interesting account of his character and manners, purporting to be from the pen of a personal friend, appeared soon after in the 'Literary Gazette,' and is extracted in the 'Ann. Biogr. and Obituary' for 1828. From that and the autobiography prefixed to the Juvenal, the facts of this account are taken.

GIFT (Law), *donum, donatio*, is the transferring of the property in a thing by one man to another, voluntarily and without any valuable consideration.

The giver is called the donor, and he to whom the thing is given is called the donee. By the common law real estate might pass as a gift by livery of seisin without deed, but by stat. 29 Charles II., c. 3, a deed or note in writing is rendered necessary to the transfer of real estate. To complete a gift of goods and chattels delivery is absolutely necessary, for until then the transaction is not properly a gift, but a contract, and the English law will not compel a man to perform his contract unless it is founded on good or valuable consideration.

Gifts are looked at with some degree of suspicion by the law of England, and are in some cases declared void, as against creditors and purchasers for a valuable consideration. [BANKRUPT.]

The distinctions laid down by the civil law as to gifts were numerous. It distinguished gifts into two classes, proper and improper: the proper gift being such as is recognised by the English law; the improper, gifts in consideration of marriage, and that species of gift termed *donatio mortis causâ*. According to the law of England marriage is a valuable consideration, and consequently gifts upon that account are supported against purchasers and creditors.

Many curious distinctions relating to gifts exist in the Hindoo law. (See Colebrooke's *Digest, Hindoo Law*, b. ii. c. 4.) As to the law regulating voluntary gifts established by the Code Napoleon, see *Cod. Civ.*, b. 3, tit. 2.

GIGGLESWICK. [YORKSHIRE.]

GIJON. [ASTURIAS.]

GIL VICENTE, surnamed the Plautus of Portugal, was born about 1485, of an old and distinguished family. Following the wish of his parents, he studied law, which he however soon abandoned for the stage. Having access at court by right of birth, he supplied several dramatic productions, adapted to different occasions, which were represented at the solemnities of the court. His plays were enacted at the court of king Emmanuel, and the first of them was performed in 1504. They had great success, which increased during the reign of Emmanuel's successor, John III., who often played a part in them himself. It appears that Gil Vicente acted himself in his dramas, and it is certain that his daughter Paula (lady of honour to a royal princess) was the first dramatic performer of her time in Portugal, and equally distinguished as a poetess and a musician. Gil Vicente preceded by almost a century Lope de Vega and Shakspeare, and being then the only dramatic author of his time, gained a European reputation. Erasmus, who was probably informed of his fame by the Portuguese Jews who sought refuge in Holland, learned Portuguese in order to read his works.

Gil Vicente may be considered as the creator of the Spanish theatre, having written in the Castilian language his religious drama, which was performed in 1504, on the occasion of the birth of the prince, who was afterwards king John III., and which is anterior in date to all the dramatic productions of Spain. He is also the model that Lope de Vega and Calderon imitated, and on which they improved. His works are, according to Sismondi, full of the extravagancies which frequently disfigure the productions of Vega and Calderon, without possessing their beauties. These faults are however excusable in the works of one who, like himself, was creating a new kind of literature; and his poetry is distinguished by richness of invention, brilliancy of imagination, and great harmony of versification.

Gil Vicente's works were published by his son in 1562, at Lisbon, in one volume folio, and republished at the same place in 4to. in 1586. The editor has divided the dramatic productions of his father into four classes, viz.: 1st, the autos; 2nd, the comedies; 3rd, the tragi-comedies; and 4th, the farces. The autos, or religious plays, of which there are sixteen, were chiefly intended for the celebration of Christmas, and the shepherds perform in them a most important part. The comedies are the worst productions of Gil Vicente, and are, like those of Spain, nothing but dramatised novels, which embrace all the life of an individual the events of which are ill connected and devoid of plot and catastrophe. The tragi-comedies may be considered as rough sketches of the tragi-comedies which were afterwards written in Spain; they contain some touching scenes: none

of them are founded on historical subjects. The farces, eleven in number, are the best part of Gil Vicente's productions, and may be regarded as specimens of the true comedy. They contain a great deal of merriment, and some well-drawn characters, but they are generally devoid of plot. It is a remarkable circumstance that the plot, which is the soul of Spanish plays, is generally neglected in the Portuguese productions of a similar kind. (For further particulars see Sismondi's *Histoire de la Littérature du Midi*, vol. iv.; and *Biog. Univ.*)

GILBERT, GABRIEL, lived in the seventeenth century, but the periods of his birth and death are alike unknown. His works are chiefly dramatic, and are sometimes referred to as specimens of badness; yet it is supposed that Racine has occasionally borrowed his thoughts, and clothed them in more elegant language. The fact of his having produced a tragedy called 'Rodogune,' in the year that Corneille brought out one with the same title, and the remarkable coincidence that the first four acts of both were nearly alike, occasioned a literary controversy as to whether Gilbert had committed a plagiarism or not. Queen Christina of Sweden entertained a high opinion of Gilbert's genius, and appointed him resident of the court of Stockholm in France. On her death he fell into poverty, when M. d'Hervart, a Mæcenas of the time, received him into his own house, where probably he died.

GILBERT, NICOLAS JOSEPH LAURENT, was born in 1751, at Fontenoi-le-Château in Lorraine. His parents, who were poor, nearly exhausted their trifling means in giving him an education. He went to Paris, and endeavoured to raise himself into notice by writing laudatory verses to great persons. This expedient failed, and he became, in consequence, tinged with misanthropy. He joined the anti-philosophic party of the times and wrote against the infidel philosophers a satire called 'Le Dix-huitième Siècle,' and another styled 'Mon Apologie,' as well as several odes and religious poems. He died at the Hotel Dieu, at the early age of 29, whither he had been removed on account of insanity, his death being occasioned by a small key, which in one of his fits he swallowed. His satires are reckoned superior to his odes, but both are severely reprehended by La Harpe as well for the thoughts they embody as for their grammatical defects.

GILD. [Boroughs of England and Wales.]

GILDAS (surnamed Sapiens, or 'the wise'), the most antient British historian now extant, according to Leland, was born in Wales, A.D. 511; but according to other accounts in 493. In the middle of the sixth century he was a monk of Bangor, and a spectator of the miseries and ruin of his countrymen. His epistle, or treatise, 'De Calamitate, Excidio, et Conquestu Britanniæ' is all that is printed of his writing; and is probably all of his that is extant: though Bale and Pits make him author of several other books. It was first published and dedicated to Cuthbert Tonstal, bishop of London, by Polydore Virgil, whose imperfect and corrupt text was reprinted at Paris in the 'Bibliotheca Patrum,' in 1610. The second edition of this work was published in the 'Opus Historiarum nostro Saeculo convenientissimum,' pp. 481–540, at Basel, 8vo., 1541: again, in a separate form, 12mo., Lond. 1568; Basel, in the same year; and Par. 1576: and lastly, from a better manuscript than was used in any previous edition, by Gale, in his 'Rerum Anglicarum Scriptores Veteres,' 3 vols. fol. 1684-7. There is also an English translation, entitled 'A Description of the State of Great Britain, written eleven hundred yeares since,' 12mo., Lond., 1652. Gildas died, according to Archbishop Usher (*Primord.*, p. 477, from the *Annals of Ulster*) in the year 570.

There were two other persons of the name of Gildas in the sixth century, one called Gildas Cambrius, the othe Gildas Quartus, both of whom seem to have been one and the same with Gildas Sapiens.

(Tanner, *Bibl. Brit. Hib.*, p. 329—332; Nicolson's *Engl. Hist. Lib.*, edit., 1776, p. 26.)

GILDING. The process of gilding is one of the most delicate in the manufactures in metal, and its success depends on a nicety of eye, a dexterity of hand, and a practical (though not necessarily a theoretical) acquaintance with the chemical operations involved in it, which cannot be acquired without several months' or even years' experience. Mechanical errors and difficulties are detected and remedied with much greater facility than those which arise in the chemical branch of manufactures. To these latter the processes of gilding and colouring are particularly subject, and more especially the process of gilding; and, in the homely phraseology of the workmen and their employers, the tenacity of the evil spirit to the gilding shop is proverbial, and his exorcism accordingly difficult.

The gold made use of for the purpose of gilding is called 'fine gold,' and is perfectly free from alloy, having been previously properly refined on the cupel, or 'test.' Its form is that which, in metals, is usually termed 'shot,' from its having been poured, or 'shot,' when in a fluid state, into cold water. This operation divides it into pieces of all shapes and all sizes, from the smallest grain, scarcely perceptible by the naked eye, to the dimensions of a pea or a nut. This form of the metal is best adapted for the purpose, because it exposes the greatest possible quantity of surface to the action of the mercury while it is boiled in it, and is thus amalgamated with a less waste of the latter metal by evaporation.

The union of the gold with the mercury is effected by boiling the former in about five or six times its weight of the latter. These proportions are put into an iron ladle, which must have been previously lined with a coating of whitening and water, and then carefully and thoroughly dried. Should there be any moisture left in the lining, or if any cracks should expose the naked surface of the iron, the ebullition of the mercury is so rapid there, owing to the more rapid conduction of the heat, that a portion of the amalgam is thrown out by the violence of the action. It is most economical to place the ladle and its contents within the heated iron cylinder used for the evaporation of the mercury from the articles when gilt, by which arrangement a considerable portion of the mercury which is evaporated during the process is retained by the condensers.

As it is not easy to ascertain by inspection the moment at which all the gold is dissolved, without which the process would be incomplete, and would have to be repeated under circumstances of greater inconvenience than the first essay, and as the continuance of it longer than requisite would occasion an unnecessary waste of the quicksilver, a practical acquaintance with the time required is commonly relied on. That time varies according to the hardness or softness of the gold (that which has been more *annealed* by the refiner appearing browner than the harder and yellower, and requiring a longer time for complete solution), and according to the larger or smaller size of the fragments of gold made use of. In general, half a troy pound of gold is completely dissolved by being kept at the boiling temperature of mercury for about twenty or twenty-five minutes. It is obvious that the boiling should be as gentle as possible, since fast boiling ensures no higher a temperature, and evaporates a greater quantity of quicksilver.

When it has been sufficiently boiled, the amalgam is poured out into cold water, by which it loses a great part of its fluidity, and becomes only semifluid, the consistence depending, of course, on the quantity of quicksilver originally made use of, and the proportion of it that has been evaporated. It is then put into a piece of chamois skin, and squeezed, by which means the particles of quicksilver escape through the pores of the leather, while thos of the gold are safely retained. It is commonly supposed that the leather, after having been once used for this purpose, and had its pores opened by being stretched out of its original shape, lets pass some of the particles of gold, but it is probable that this notion rests upon the traditionary imaginations of the operatives, rather than upon any experimental proof of its correctness. When the mass is felt to be hard and unyielding within the leather, it is weighed, and its value is determined by considering five parts by weight of the amalgam as equal to one part by weight of the gold employed. The amalgam then, if good, is of about the consistence of a stiff clay, has a greasy and gritty feel on being divided by the bone spatula, and is in the most convenient state for being weighed out into the portions requisite for each respective quantity of work. If however the gold be adulterated or the mercury be impure, it often approaches more or less to fluidity, appears dirty, and deposits a black adhesive scum on every thing with which it comes in contact. Even the very best amalgam may be reduced from an almost solid to a fluid form by beating, pressing, and agitation, but it returns to its original state on being left for a few minutes in a state of quiescence.

The main object of bringing the amalgam to this consistence and these proportions is to have it in a form con-

venient for division and apportionment, as well as for the sake of having a uniform standard by which to ascertain the quantity and value of the gold employed. Gold, in the pure state required by gilders, is usually of the value of 4*l.* 7*s.* 6*d.* per oz. troy; quicksilver, about two or three years ago, was worth about 2*s.* 6*d.* per lb. avoirdupois, but owing to a monopoly of the European mines it has more lately varied from 3*s.* 6*d.* to 4*s.* 6*d.* per lb. The amalgam, made in the proportion of one-fifth gold, is reckoned by manufacturers to be worth 1*s.* per dwt., including the gilder's wages and the materials made use of in its application; and this estimation, it will be perceived, will allow for some fluctuation in the value of its ingredients. To this it may be added, that the gold, being in this form less obviously apparent, does not offer so strong a temptation to the honesty of those to whom it is entrusted for use. As, however, this consistence is not adapted for being applied to its intended purpose, without a greater or less dilution by being again boiled for an instant in mercury, many gilders, especially those who provide their own gold, prefer to weigh out the gold which they intend to use, and then to mix it at once with the quantity of quicksilver which experience has taught them to be proper and necessary, and which varies according to the nature of the articles to be covered with it; those which are wrought into deeply indented or highly ornamented patterns, or which are to have their surfaces completely covered, requiring a more fluid amalgam than those which have a smoother superficies, or which are to be only partially gilt.

On the application, however, of this amalgam to the surfaces of either gilding metal, copper, brazen, or similored articles, it is found that as there is no chemical affinity, and consequently no principle of mutual cohesion between the substances thus brought into contact, the direct union of them is impossible. Nor can it be effected by allowing them to remain in contact for any length of tim such an experiment, were it continued for several weeks or months, would be productive of no satisfactory result. The intervention of a solution of nitrate of mercury is therefore used, and it is made by pouring a table-spoonful of quicksilver into about a quart of strong nitric acid, which is termed in commerce 'gilders' aqua fortis.' The red fumes of nitrous gas are instantly evolved, and the mercury is rapidly united with the acid, with the production of considerable heat. This solution is, by the unscientific operatives, termed 'quick-water,' the monosyllable 'quick' being, in their language, a sufficient representative for the more tedious appellation of 'quicksilver.' When it is uncontaminated by the presence of any foreign substance, the 'quick-water' is white and pellucid, nor can it be distinguished from common water except by the slight alteration in appearance which its different refractive power shows to a keen and experienced eye.

When a piece of copper or brass is immersed in or brought in contact with this solution, its surface is immediately converted into an amalgam. The *rationale* of this phænomenon does not seem to have received any explanation in the chemical treatises and popular works hitherto published; but it appears to depend upon a peculiar galvanic circuit formed between the mercury and the copper in the acid medium. To this amalgamated surface mercury and gold amalgam closely adheres, by means of what is termed the molecular attraction of the particles of the fluid metals for each other.

The manner in which this agent is applied in practice varies according to the description of articles to which it is to be applied. If they are small, strong, and to be gilt all over, as copper buttons, buckles, and rings, a quantity of them, which should not exceed three or four pounds in weight, is put into a deep glazed earthen pan, or 'jowl;' to these are added about three or four tea-spoonfuls of the 'quick-water,' together with the requisite portion of amalgam. The whole is then thoroughly stirred with a brush or stick, till the amalgam entirely covers the surface of every article, more particularly the indentations and sunk parts, which are the last to receive a coating, from their being less exposed to the contact of the fluids. When they are completely covered they are by some gilders rinsed in cold water and dried by shaking in a bag of warm sawdust, while by others this part of the process is postponed to a later period of the operation, and they are put, in their wet state, with the generated nitrate of copper still hanging about them, into the cage.

The 'gilding cage' is made in a cylindrical form, and is generally about 18 inches in length by 9 or 10 in diameter. It is formed of coarse iron-wire gauze, supported by an external framework of iron, and furnished with a solid iron door at one extremity, which generally forms a sector of one-third of the circular end. It is provided with an axle, which extends to a length of about three feet from the end at which the door is placed, and is then terminated by a winch, and to a distance of five or six inches in the opposite direction. The articles under process of gilding are placed in this cage, and the door of it securely fastened; it is then suspended by its axle on two supports in an iron cylinder, which something resembles a gas retort, and which is in a similar manner fixed into brickwork over a furnace or stove. The cylinder being previously heated by a coal fire beneath it, to such a degree as to be red-hot over a large proportion of its inferior surface, the cage is introduced, and the doors of the cylinder closed, which do not however fit so accurately as to exclude all access of air to the cylinder, or to prevent a tolerable draught from passing through it. The heated air contained within the cylinder soon raises the temperature of the substances immersed in it, and as the case is kept continually revolving by means of the winch, which projects through an aperture in the doors, they have all an equable share of heat, and allow of a nearly equal evaporation of the mercury from all their surfaces.

The farther extremity of the cylinder communicates with a chamber, which is in general built of masonry and plastered over all the internal surfaces. The floor of this chamber is covered to a depth of about two feet with cold water, which on coming into contact with the mercurial vapours condenses a portion of them, and causes them to return to the liquid form. If this 'condenser,' however, were made quite close, a great portion of the mercurial vapour would return through the cylinder into the apartment or 'gilding shop,' and thus not only be wasted, but materially injure the health of the persons engaged in the work. A communication extending obliquely upwards, and made of one or more ranges of iron stove piping, is therefore connected with a second smaller condenser on the story above, and this is again repeated a third or perhaps a fourth time. A current of heated air is thus continually ascending from the lowest condenser, and establishes a perpetual draught through the cylinder, thus preventing the deleterious mercurial vapour from mixing with the atmosphere of the shop in which the work is going forward, and injuring the health of those employed in it. It is obvious however that by means of the continual free ascent of the vapour a great proportion of it must be lost in the external air, and be irrecoverably wasted. If the draught be so good as entirely to prevent the contamination of the air of the room, about half the quantity of quicksilver employed will perhaps be found the highest average amount retainable in practice. The condensers are opened usually once a year, and the quicksilver taken out, washed, and dried, and it is sometimes found necessary again to distil it, to purify it from all impurities.

After the cage, with its contents, has been in the cylinder for a length of time varying, according to the temperature at which it has been kept, from five minutes to a quarter of an hour, the mercury will be found to have entirely evaporated from the gilt surfaces. If the articles have been previously washed and dried, they will appear of a clear yellow colour, and they may be allowed to remain in the cylinder, the cage revolving as before, until they are sufficiently 'heightened.' If they have not been so treated previously, they will appear of a dark, soiled, dirty colour, being covered with an incrustation of oxide of copper and of iron, and other impurities. To remove these, the goods are taken out of the cage: and after being allowed to cool for a few minutes, they are thrown, while still warm, into 'weak quick-water,' *i.e.* diluted nitrate of mercury. This converts the gold again into an amalgam, owing to the precipitation of a portion of the mercury by the copper, which is taken up with avidity by the gold. They are then washed with clean water, dried in warm sawdust, and again committed to the cage and cylinder, which, by the evaporation of the mercury, give them a clean colour. They may then be heightened, which is done by continuing to revolve them at the same high temperature within the cylinder, occasionally taking out the cage and shaking them together, that they may all have an equal share of the heat, until the copper throws up a thin coating of oxide upon them, which

exhibits a prismatic mixture of various colours, from yellow, through red, violet, and brown, to almost a black. The thicker the coating of gold is, the longer may this process be continued: if the oxidation be carried too far, it occasions a scaly incrustation, which causes the gold to fall off, and renders the whole operation worse than useless, inasmuch as articles can rarely be gilt a second time with success.

The oxidation of the copper however is not the object intended to be effected, or rather it should be said that it is not the purpose for which it is done, though it furnishes a very accurate indication of the extent to which it should be carried. The end intended to be effected is a partial oxidation of the surface of the gold, caused by means of the increased temperature of the metal goods after the mercury has evaporated, and which remains unaffected by nitric or sulphuric acids after the slight film of oxide of copper has been instantaneously removed by their action. This partial oxidation occasions a slight difference of colour, which is perceptible by an experienced eye, and confers on the gold a degree of that orange colour which is so generally admired in golden and gilt articles. The degree to which the 'heightening' ought to be carried differs according to the quality of the gilding. Those which are richest and best gilt may be heightened till they are of a brown colour; the commoner sorts not so much; and yellow similored goods must only have the mercury fairly removed from them.

Buttons and articles of a similar description are often gilt only on their tops, or on some other portion of their surfaces, while the remainder is left uncovered with gold, and of the native colour of the metal of which they are manufactured. This is accomplished by brushing them over the part to be gilt with a hard brush wetted with 'quick-water,' or by rubbing it with a piece of chamois leather similarly moistened. In order to accelerate the process in buttons, &c., they are arranged on boards in holes adapted to receive and retain them; and the 'quick-water' is then applied by the brush. They are afterwards briskly rubbed with a dry brush, which gives them a brilliantly shining metallic lustre, and a colour between that of lead and of silver. They are then put into the 'gilding-cap,' which is a whit felt hat of a peculiar sort and shape. The amalgam for this description of work is brought to a much stiffer consistence than that which is used for 'all-overs,' and is put into the gilding-cap along with them. The whole is then well shaken together for a few minutes, when the amalgam will be perceived clinging to the amalgamated parts of th goods, but leaving the remainder in their original state. They are then put into the cage, the mercury is evaporated and they are afterwards 'quick-watered' in the manner already described.

Many descriptions of articles would be injured or destroyed by the method of gilding just now described. Such are all those which are of considerable dimensions in proportion to the thickness of the metal out of which they are made, as well as those whose individual weight and extent of surface would expose them to such attrition from the rotatory motion of the cage as would occasion the gold laid on to be entirely or partially rubbed off in the process of its application. Besides this, there is in thin and fragile articles an imminent danger of their being broken when they are amalgamated and rendered brittle throughout a great part of their substance by the necessary immersion in the quick-water. To obviate the inconveniences that might result from these circumstances, a different method is employed, so far as regards the mechanical part of it, though the chemical principles on which it depends are precisely the same. Articles of this description are most commonly gilt only on one side, and there are two modes of preventing the amalgam from adhering to those parts of the surface that are intended to be left bare. One is to lacquer those parts (which are of course concealed when the article is fitted to the spot for which it was made), and after the spirit of wine is thoroughly evaporated, to immerse them in the quickwater, and afterwards apply the amalgam. The gummy surface left behind by the lacquer is entirely unaltered by its contact with the mercurial solution, but its exposure to the high temperature necessary in the subsequent parts of the process chars the gum, blackens it, causes it to peel off, and sometimes, if it be not very carefully dried at first, occasions portions of it to adhere to the gilt surfaces of other goods with which it comes in contact by being gilt along with them. The other mode of applying the gold is to distribute the quick-water over the parts requiring it by a small brush or camel's hair pencil, and these then have the amalgam applied as before. If, as is sometimes the case, the goods are to be entirely covered, they are immersed at once in the quick-water.

The goods thus prepared are laid with the gilt surfaces uppermost on an open iron pan, of a shape something like that of a frying-pan, which is held over a coke fire by the operative. The chimney is made wide at the bottom, and narrows rapidly as it proceeds upwards, so as to collect as much as possible of the mercurial vapour, for the recovery of which no effort has hitherto been made. A great proportion however necessarily escapes into the apartment, and renders this mode of gilding much more unhealthy than the use of the cylinder and cage. As the mercury gradually evaporates from their surfaces, their position is changed, when requisite, by means of a short pair of tongs; and when entirely free from it, the process of 'quick-watering' is performed.

It is entirely foreign to the present object to give any remarks on the medical effects of mercury on the human frame. Its consequences, as practically experienced by gilders, consist in soreness of the mouth from salivation, nausea and sickness, an oppressive head-ache, and, after the lapse of a few years, a paralytic tremour and agitation in all the muscles of the body; nor does any treatment seem to be successful which does not include an entire abstinence from the prosecution of this occupation, and even this is unavailing when 'the shakes' have taken possession of their unhappy victim. Distressing instances have been known of this last and worst stage of the effects of the poison, in which the unfortunate sufferer was not only deprived of the power of locomotion, but unable to retain a grasp of even the smallest and lightest utensils made use of in domestic life. The introduction of the cylinder and cage (which, simple as they may seem, have not been in use very many years), has greatly abated this serious evil; and those operatives the nature of whose work prevents them from calling in these accessories may prevent a great portion of the mischievous consequences likely to ensue by a minute and scrupulous attention to cleanliness. A gilder who had by the age of about fifty amassed a little competency by his trade, sufficient to enable him to retire from business, ascribed the unbroken health he enjoyed to the practice of employing about an hour every evening in cleansing his nails and fingers from the minute particles of quicksilver left on them by the labours of the day. He was one of those who work over an open fire.

Where the cylinder is employed, it should be swept out daily, before the fire has heated it in the morning. A portion of the gold amalgam is rubbed off by the attrition of the cage, and falls on the inferior surface of the cylinder, whose heat melts it wholly or partially, and it becomes mixed with the oxide of iron that is constantly in course of production by the elevated temperature of the cylinder. This being carefully collected and refined, is found to yield an average of about 1-30th of the gold employed, to which dividend the richer sorts have contributed from their superabundance a greater proportionate quantity than the commoner qualities.

Much has been said and written respecting the extensibility of gold under the hammer; but this property is much more remarkably developed in its application to gilding. Similored articles are the best adapted to show the extent over which the metal can be spread, since the brass amalgam seems to have a more powerful affinity for the amalgam of gold. In this description of goods a grain of gold will cover about 40 square inches, without leaving a single aperture bare that is perceptible to the naked eye or to magnifying glasses, or discoverable by the action of aquafortis. A cubic foot would therefore cover about 402,640,000 square inches, which gives a thickness for the coating of gold of about 1-233,000th of an inch.

The profits of those engaged in this department of manufactures vary greatly, but they bear a very high proportion to the average of those of the individuals engaged in most other branches. These high profits are a sort of remuneration for the unwholesome nature of the trade, which by its real and imaginary terrors (of which the latter are perhaps the greatest) creates a general reluctance in the working population to allow their children to be brought up to it or to enter it themselves. A gilding woman's wages, who works by the day, are about 4*d.* an hour for six hours in the middle of the day, and 6*d.* an hour for extra time. A

man's time is paid for at a rate of about three times as much, in both instances. But those who are called 'out-gilders,' who find the gold, and charge for the materials and labour together in the gross, are in the receipt of larger profits. The average of some of the more fortunate instances are known only to those who enjoy the advantage, but it may be conjectured that it often amounts to 20*s.* a day. A great deal depends on the power of producing a good appearance with a small quantity of gold, as also upon the colour laid on, which most generally depends on a diversity of preparations and mixtures, which are always kept a profound secret, which is to be revealed only for an adequate remuneration.

There is a remarkable difference between the workmen in this branch in London and in Birmingham, which are the principal and indeed almost the only places where it is carried on. In London, a rich dead orange colour is produced, which is greatly superior to anything that a Birmingham man can turn out; but, on the other hand, a London workman cannot gild common articles at all nor can he attain his object without a greater expenditure of gold than a Birmingham man. Thus London gilt articles are expensive but good; while those gilt at Birmingham are better in proportion to their price, but they cannot be brought up to the standard attained by the workmen of the metropolis. The modes of their procedure are however essentially the same, the whole of the difference lying in the minor details.

Gilt articles of all the better qualities are submitted to an after-process called colouring, for the purpose of conferring on them a deeper orange tint than is natural to the gold itself, or can be obtained by the process of heightening already mentioned. The principle of this additional operation is always the same, though the methods resorted to differ greatly from each other. One of the most usual is a mixture which contains ingredients and proportions closely resembling the following recipe, though perhaps no two unconnected gilders are precisely uniform in their practice:—Twenty-four parts of nitrate of potash, ten of sulphate of alumina, five of sulphate of iron, and five of sulphate of zinc, are boiled together in water, thoroughly mixed, and cooled without being allowed to crystallize. This mixture is formed into a thin paste with water, which is spread over the surfaces of the articles by their being immersed in it, and when they are placed on a heated iron plate, the warm gold surfaces become oxidized by their contact in that state with the oxygen that forms so large an ingredient in the composition of the saltpetre (nitrate of potash) and of the other salts employed. A mixture is sometimes made of bees' wax and yellow ochre, which being rubbed over the gilt surfaces and burnt off, occasions on a similar principle the same result. Goods that are to appear bright are scratched over before colouring with a brush made of fine brass wire.

Most gilt articles are burnished by a stone burnisher, formed of a polished piece of the mineral known to scientific men by the name of black hæmatite, which is a sort of natural steel, very hard and susceptible of a very high polish. This is fixed into a proper handle. Small articles, as buttons, &c., are placed in a lathe, and the stone applied to them as they revolve, and those that do not admit of this are burnished by hand on a table or bench.

Besides copper and brass, several other substances admit of being gilt.

Silver is gilt in a manner similar to that above described.

Steel and iron are gilt by being immersed in a mixture of the nitro-muriate (or more properly the chloride) of gold with sulphuric æther or alcohol. By combining these liquids together, an alcoholic solution of gold is formed, from which the metal is precipitated by the iron or steel. A patent has lately been taken out for gilding copper and brass by a method which appears to be analogous to this; but though the invention displays considerable knowledge of theoretical and practical chemistry, and much ingenuity in adapting it to this object, there are objections attending its actual practice which will ever prevent its coming into general use.

Ivory may be gilt by immersing it first in a solution of sulphate of iron, and afterwards in one of nitro-muriate of gold.

The edges of the leaves of books are gilt by applying to them a composition of four parts Armenian bole, and one part sugar-candy, ground together with the white of eggs. Gold leaf is afterwards applied, and they are subsequently burnished by the stone.

The gilding of porcelain is accomplished by the application of gold-leaf during the process of its manufacture, which is fixed by that intense heat which confers on this substance its enamel or glaze, and is afterwards burnished by a stone as above described.

Carved wood is gilt by means of the following process:—Some size is dissolved in water by heat, and a little whitening mixed with it. This composition is brushed over the picture-frame or other article to be gilt. The holes and cracks that may be in it are then filled up with a mixture of the same ingredients in different proportions, and of about the consistence of putty. A composition of the same sort, but containing more whitening than the first, is then brushed over it, and allowed to dry. This is repeated till a sufficient thickness has been laid on. The plain parts are then moistened, smoothed down with a Dutch rush, pumice stone, old file, or anything similar, and the corners and mouldings are squared and shaped by proper tools. A composition similar to the last, but in which yellow ochre is substituted for whitening, is then laid on in a thin coat by a brush. This when dry is again covered by a coating of gold size, a peculiar composition, of which deers' fat is said to form the principal ingredient. This is allowed to dry. The frame or other article thus prepared is placed in a sloping position; its parts are successively moistened with water; gold-leaf is laid on them by a 'tip' (a sort of comb formed by inserting a row of camel's hairs into a card), and is pressed down into the cavities by a dry camel's hair pencil. The gold when dry is burnished in the usual manner by a stone.

Another method is to cover the coating of yellow ochre and size with another of oil varnish, and when this is almost dry, or (as it is technically called) 'luggy,' to apply the gold-leaf, which is pressed down into the mouldings by clean cotton. This is afterwards rubbed over with clean cotton to polish it, and when the varnish is quite dry it becomes very hard and solid.

Glass may be gilt by the following simple method:—Dissolve some isinglass in water by means of heat; evaporate the liquid, and allow it to crystallize. Re-dissolve some of the crystals, and after making the mixture of the usual consistence of glue, dip into it a piece of clean chamois leather, which is to be drawn once, and only once, over the parts of the glass that are to be gilt. Lay on the leaf-gold, which will adhere, and allow the whole to dry. On this coating of gold another may be placed in a similar manner, being careful to draw the isinglass only once and lightly over the former coating. It will be generally found advisable to repeat this process a third time. Any superfluous gold may be removed by a sharp stick, and the gilt parts are to be polished by rubbing them with clean cotton, which will obliterate all traces of any joinings, and prevent them from being visible from either side of the glass.

The applications of gold-leaf to leather, paper, wood, and other substances, are numerous and diversified, but what has been said above will be sufficient to indicate the principles and details of this branch of the arts.

GILEAD. [PALESTINE.]

GILLIESIA'CEÆ, a very singular natural order of Endogens, with the habit of the Scilleous division of Liliaceæ, but with extremely remarkable flowers. In the first place there are several bracts at the base of each flower, resembling a calyx, and in reality constituting an involucre; and secondly the calyx is either an urceolate six-toothed body, or a single lobe resembling a labellum. Of the two known genera, one has six perfect stamens, the other has only three perfect and the remainder sterile and nearly obliterated. They are natives of Chili; one of them, Gilliesia graminea, has been figured at folio 992 of the 'Botanical Register,' where a full account of it will be found.

GILLS. [FISH.]

GILLY. [HAINAULT.]

GILLYFLOWER, the common name of the garden stock, Mathiola incana. [MATHIOLA].

GILOLO. [MOLUCCAS.]

GILPIN, BERNARD (born 1517, died 1583), is one of those persons who, without having been placed in stations which afforded the opportunity for the display of extraordinary intellectual powers, or having had the course of their lives marked by very unusual and extraordinary accidents, yet occupy no inconsiderable space in the eye of their countrymen, and are regarded with affection and respect, as ornaments of their time and an honour to the nation to which they belong. This is owing in part to the popular character

of his virtues, and in part to his having had in Bishop Carleton a contemporary biographer, who has given a pleasing and no doubt faithful account of his life and manners. In later times, one of his own family, the Rev. William Gilpin, of Boldre (of whom in the next article), prepared a larger account of this venerable character in his own singularly pleasing style of composition.

Bernard Gilpin was born in Westmoreland, of a genteel family, and by his mother was related to Cuthbert Tunstall, one of the most enlightened churchmen of the time, who being bishop of Durham had the means of placing his relation in the valuable rectory of Houghton-le-Spring, and at the same time giving to the parish a pastor singularly well adapted to the state of society in that parish and its vicinity. But before he became rector of Houghton-le-Spring he had shared in the sufferings of the Protestant clergy. Early in the reign of Queen Mary he resigned a small living in the diocese of Durham, and went abroad, as did many others who had been favourers of the Reformation in the days of King Edward. He was absent three years. He ventured to return while Queen Mary was alive; and was cordially received by Tunstall, who made him archdeacon of Durham and rector of Houghton. His preaching at this period was bold. He inveighed against popular vices in the spirit of an enthusiastic reformer; and when this brought upon him much odium from persons who were touched by him, and he was accused to the bishop of Durham, the bishop protected him so effectually, that his accusers brought their charges before Bonner, the bishop of London, whose memory is held in execration for his insolent behaviour and his needless severities. This led to a remarkable incident. Gilpin obeyed the summons of this unpitying prelate. Full of the expectation of nothing less than to suffer at the stake, 'Give me,' said he, before he set out, to his house-steward, 'a long garment, that I may die with decency.' As he journeyed with the ministers of the bishop, an accident happened to him which occasioned a delay. It is said that his leg was broken. While he lay without the possibility of proceeding, intelligence came that the queen was dead. A change of system instantly took place, and Gilpin returned in joy and peace to his parishioners at Houghton.

The only other incident in his life which requires notice is, that the bishopric of Carlisle was offered to him by Queen Elizabeth. This offer he declined, and continued to his death the rector of Houghton, residing constantly in his parish, except when he visited the ruder parts of the county of Northumberland, into which he appears to have introduced more of regular habits of life and more of Christian influences than had resulted from the labours of any previous Christian instructor who had lived amongst them.

The parts of Redesdale and Tynedale, debatable land on the Marches, are particularly named as the scenes of his labours. The people there, living on the borders of the two countries, had long led a lawless life, subsisting mostly on plunder. Gilpin went fearlessly amongst them, holding forth the commands and the sanctions of Christianity, and did much to change the character of the country. Hence it was that he was often called the Northern Apostle.

His own parish of Houghton however was the chief scene of his labours. It yielded him an ample income, for Houghton was then, as now, one of the richest benefices in the North. He was himself a bachelor. In hospitality he was like what is said or fabled of the primitive bishops. Every fortnight, we are told, forty bushels of corn, twenty bushels of malt, and a whole ox, were consumed in his house, besides ample supplies of provisions of many other kinds. The rectory-house was open to all travellers, and so great was the reverence which surrounded the master, that his liberality was rarely abused; even the most wicked being awed by it.

His skill in according differences was scarcely less famed than his hospitality and his preaching; and when to this we add that his benevolence took the wise direction of providing instruction in human learning for the young, and that he was assiduous in his attention to the sick and to the poor, we have touched upon all the points which can be prominent in the life of a good pastor. His zeal for education was manifested at once in the education of the poor children in his parish in homely learning, and in patronizing promising youth in their studies in the universities. He was sometimes called the Father of the Poor.

Thus this good man lived and died. No one can doubt that he did great good in his day and generation in that remote part of the kingdom; and his memory being so well embalmed, as little can we doubt that his life has influenced many since his time to be faithful and zealous pastors of the church, blessing and blessed of that portion of it which was committed to their charge.

GILPIN, WILLIAM (born 1724, died 1804), was of the same family with Bernard Gilpin, being the sixth in descent from William Gilpin, his elder brother. There was another divine in this family, of not sufficient note to have a place in a general biographical dictionary, yet not wholly to be passed over:—Dr. Richard Gilpin, who resigned the rectory of Greystock, in Cumberland, on non-compliance with the terms of the Act of Uniformity in 1662, and continued a dissenting minister till his death, in 1699. This Dr. Richard Gilpin was the great-grandfather of William Gilpin, whose father, an officer in the army, had a narrow escape from being the military governor of Carlisle, at the time when it was taken by the rebels in 1745, having been shortly before superseded in his command there by an officer sent thither by the duke of Cumberland.

Mr. Gilpin took orders, and lived for some time on a curacy in the north, among his relations; but having only a small fortune, and marrying a young lady, his cousin, whose fortune also was small, and having but little hope of patronage in the church, he removed into the neighbourhood of London, and took a school at Cheam, in Surrey, which he conducted skilfully and successfully for many years. Among his pupils were the present Viscount Sidmouth and Lord Bexley, and the late Colonel Mitford, the author of the History of Greece.

Mr. Gilpin is said, by the friend who has drawn a very pleasing picture of his life and manners, to have resolved to retire from the duties of a schoolmaster whenever he had realized 10,000*l.*; and having at length succeeded in this, he adhered to his resolution, and it happened fortunate for him that at the same time his former pupil, Colonel Mitford, presented him to the living of Boldre, on the borders of the New Forest, Hampshire. To this village Mr. Gilpin retired, and here he spent the remainder of his life, scarcely ever leaving it, in the active discharge of the duties of a village pastor, and being, like his venerable ancestor, a blessing to the place. Here he died on April 5, 1804, at age of eighty, and is buried in the churchyard, where also lies his widow, who survived him three years, 'hoping to be raised in God's good time, when it will be a new joy to see several of their good neighbours who now lie scattered in those sacred precincts around them.'

Mr. Gilpin however is not to be regarded only in his character of a good schoolmaster and an excellent parish pastor; he has enriched the literature of his country with several valuable writings in various departments. His first work was a 'Life of Bernard Gilpin,' and it was soon succeeded by a 'Life of Latimer,' who bore some resemblance to Gilpin. At a later period of life he published lives of Cranmer, Wickliff, Huss, Jerome of Prague, and Zisca. He was the author also of a body of 'Lectures on the Church Catechism,' an 'Exposition on the New Testament,' a 'Treatise on the Amusements of Clergymen,' and 'Sermons for Country Congregations.' These works are all written in a style of simplicity which is singularly engaging.

But Mr. Gilpin was a person of a remarkably refined taste, as is evinced by writings of his of a class entirely distinct from those we have enumerated. These are his volumes in which he has illustrated, both by his pencil and his pen, the picturesque beauty of some parts of England, and, generally, the principles of beauty in landscape. The first of these works was published in 1790, in two volumes, 8vo.; it was entitled 'Observations relative chiefly to Picturesque Beauty, made in the year 1776, in several parts of Great Britain, particularly the Highlands of Scotland.' This was followed by two other volumes of the same character, the greater part of them relating to the lake country of Cumberland and Westmoreland. Two volumes more, on 'Forest Scenery,' succeeded. Besides these, there are his 'Essays on Picturesque Beauty;' 'Picturesque Travels and the Art of Sketching Landscapes;' 'Observations on the River Wye;' and 'Picturesque Remarks on the Western parts of England.' These form a body of works which were well received by the public at the times of their appearance, and which are now gathered into the libraries of the tasteful and the curious, so that copies rarely present themselves for public sale. One work more of Mr. Gilpin's must be named, his 'Essay on Prints,' in which he did not

profess to do more than touch on the more prominent points of his subject. Some 'Observations on the Coasts of Hampshire, Sussex, and Kent,' were published after his decease.

For the principal part of this article we have been indebted to a memoir on his life inserted in a periodical work published at Bath, and intitled 'The Omnium Gatherum.' It contains much more information concerning him, and extracts from his correspondence. The writer is understood to be the Rev. Richard Warner, who was sometime curate to Mr. Gilpin.

GIN, a spirituous liquor prepared by the rectifying distillers of England by means of flavouring ingredients added during the rectification of spirit distilled from barley. [DISTILLATION.] The name Gin is derived from that given in this country to the spirit imported from Holland, viz. Hollands-Geneva, which was formerly much consumed in this country, but the use of which has during the last forty years been nearly discontinued in favour of British gin, made in imitation of the Dutch spirit. The principal flavouring ingredient used both in Holland and in England, the only one indeed, the employment of which is acknowledged by the rectifiers, is the juniper-berry. Gin is principally consumed by the working classes in England; and its use does not extend to Scotland or Ireland, in both which parts of the kingdom its place is supplied by whiskey.

GIN. [COTTON.]

GINGER. [ZINGIBER.]

GINGUENÉ, PIERRE LOUIS, born at Rennes in Britanny, in 1748, early applied himself to the study of literature and of foreign languages. Having removed to Paris he made himself known by several works, especially by his poem on the death of the young Prince Leopold of Brunswick, who was drowned in the Oder whilst trying to save some poor people who were in danger of perishing in the flood. In his 'Lettres sur les Confessions de J. J. Rousseau,' he undertook to defend the memory of that highly-gifted but wayward man. When the Revolution broke out, Ginguené embraced its cause, but did not advocate its excesses; he wrote in several journals of the time, and edited the 'Decade Philosophique Littéraire et Politique,' from 1794 to 1807. On being made a member of the Institut, he was placed at the head of the department of public instruction. He was afterwards sent by the Directory in 1798 as ambassador to the king of Sardinia, where he had a most difficult task to perform, that of reconciling his conscience, naturally honest and candid, with the crooked and ungenerous policy of his masters towards a forced ally, whom they tried to vex and insult in every possible manner, with the view of seizing a favourable opportunity to dethrone him. Botta, who knew and esteemed Ginguené, gives in his 'History of Italy' a full account of disgraceful and calamitous scenes that took place in Piedmont at the time. Ginguené seems to have felt the unpleasantness of his position, for after seven months he resigned his embassy and returned to Paris, where he had a seat in the legislative body. After Bonaparte became first consul in 1799, Ginguené was chosen member of the tribunate, but owing to his opposition to the encroachments of the executive he was one of those who were ejected by a Senatus Consultum in 1802. He withdrew into private life, and applied himself chiefly to the composition of a work which he made the business of the remainder of his life—the 'Histoire Littéraire d' Italie,' 9 vols. 8vo., 1811-19.

He had always been very partial to Italian literature, and perceiving that his countrymen had no accurate notion of its riches and had imbibed several vulgar prejudices against it, he undertook the arduous task of classing the numerous productions of Italy under each respective department of literature and according to the order of time, thus presenting the reader with so many sketches of the intellectual state of Italy in each century. His history begins, properly speaking, with the thirteenth century, when the first lays of the Italian Muse began to be heard. In the first three volumes he follows the progress of literature through the thirteenth, fourteenth, and fifteenth centuries; after which he devotes six more volumes to the sixteenth century, the Augustan age of modern Italy. He died at Paris in November, 1816, without completing his work, which has since been continued by Salfi, who has published five more volumes, 1823-35, bringing it down to the close of the seventeenth century. It is an important and useful work, and in some respects preferable, because more critical and more freely written, to Tiraboschi's more ample and classical work, 'Storia della Letteratura Italiana,' from which Ginguené borrowed largely. Ginguené writes impartially, and as accurately as could be expected from a foreigner who had not lived in Italy, except during the seven stormy months which he spent at Turin, merely on the threshold of that country. His minuteness is sometimes fatiguing, and his style rather tame for the subject. The Italians have felt grateful to him for the honour which he has done to their great men, but have observed that he has been lavish of praise to many writers who are utterly forgotten in their own country. (Ugoni, Preface to the *Storia della Letteratura Italiana.*) Valéry, in his 'Voyages Littéraires en Italie,' corrects several inaccuracies of Ginguené.

Ginguené had collected a good library of Italian writers for his great work, of which a catalogue has been published, and which was sold after his death. He wrote also many articles for the 'Biographie Universelle,' and was a contributor to the 'Histoire Littéraire de France,' and other compilations. Salfi gives at the end of the first volume of his continuation, which is numbered the tenth of the 'Histoire Littéraire d'Italie,' an 'Eloge' of Ginguené.

GINKELL. [ATHLONE.]

GINSENG, a root found in China, to which extraordinary properties have been ascribed; it is not only considered a universal remedy for all maladies, but is spoken of in the highest terms as a specific in particular circumstances. Volumes have been written in Chinese upon the supposed virtues of this root; it is affirmed that it wards off fatigue, invigorates the enfeebled frame, restores the exhausted animal powers, makes old people young, and so on. The weight in gold has been given by the Chinese for this root, which we are told grows only in the most remote and inaccessible parts of Chinese Tartary, where its collection is attended by dangers sufficient to appal the stoutest man. Nevertheless botanists believe the Ginseng to be nothing more than a plant called Panax quinquefolium, also found in North America, where no such qualities as those spoken of by the Chinese are recognised. It is however not certain that this identification is correct; indeed it is hardly to be supposed that such extraordinary faith in the energies of the plant can be altogether destitute of foundation. Nothing better deserves scientific investigation.

GIO'JA, MELCHIO'RRE, born at Piacenza in 1767, studied in the college Alberoni of that town, after which he was ordained priest. He showed at an early age a predilection for the mathematical sciences. When Bonaparte invaded Lombardy in 1796, Gioja went to live at Milan, adopted republican opinions, and became a political writer. The Provisional Government at Milan having offered a prize for the solution of the question, 'Which of the various forms of free government is best suited to Italy?' Gioja obtained the prize. He advocated a constitution on the model of the French one of 1795, with two elective Chambers, an executive Directory, &c., but with some modifications, by which he really believed that the establishment of liberty and political equality would be secured. The result proved unfavourable; the Cisalpine Republic, a mere dependant of France, after changing its constitution two or three times in as many years, fell before the arms of Austria and Russia in 1799. It is but justice to say that during this turbulent period Gioja wrote the following pamphlets, chiefly in reproof of fanatical or dishonest revolutionists who advised measures of confiscation and proscription against all those whose opinions were different from their own:—1. 'Quadro Politico di Milano.' 2. 'Cosa è Patriotismo?' 3. 'I Partiti chiamati all' Ordine.' 4. 'La Causa di Dio e degli Uomini difesa dagl' Insulti degli Empj e dalle Pretensioni dei Fanatici.' All these are curious memorials of the aberrations of opinion in those times. Gioja, after being imprisoned as a republican in 1799, was liberated in 1800, after the battle of Marengo. He now applied himself chiefly to political economy, and it is upon his works on that science that his reputation is founded. He wrote, in favour of a free trade in corn and other provisions, 'Sul Commercio dei Comestibili, e caro prezzo del vitto,' Milan, 1801. The price of bread continued however to be fixed for years after by the municipal authorities in the towns of Lombardy His description of the department dell' Olona, or of Milan, and of that del Lario, or of Como, was considered as a model for statistical works. When Napoleon crowned himself king of Italy, Gioja resumed his political pamphlets, and wrote, 'I Tedeschi, i Francesi, e i Russi in Lombardia,' in which he maintained that the dominion of the French

was more congenial to Italy than that of the other two. He was soon after appointed historiographer of the kingdom.

Gioja's reputation rests on his 'Nuovo Prospetto delle Scienze Economiche,' 6 vols. 4to., Milan, 1815-17; a work of considerable research and labour, in which the author has collected and examined the opinions of most economists, Italian and foreign, and tried them by a comparison with the historical facts and institutions of various nations, antient and modern. The greater part of the work is in a tabular form, the tables being furnished with quotations and notes. Gioja prefers large properties to subdivided ones, arts and manufactures to agriculture, and he advocates the principle of association as a powerful means of production; he is also in favour of a system of universal popular education. At the end of the sixth volume he gives a list of cases in which the interference of the government may be useful to industry, and another of those in which it is mischievous. As a sequel to this work he published a treatise, 'Del Merito e delle Ricompense,' 2 vols. 4to., 1818-19, a work full of bold and original ideas, many of which may be highly useful, whilst others appear impracticable in the present state of society. In it the author exhibits a total independence of all political systems, very different in this respect from his former political productions. He strives to ascertain and fix a standard for the various kinds of merit or value, physical, intellectual, and accidental, of men, and to point out the authority which is to estimate the same. This last subject engrosses a chapter which is perhaps the most curious in the whole work. Few of the advocates of the political rights of the people have openly faced the question of the capabilities of the majority of that people for exercising those rights. Gioja has not shrunk from the thankless task. This chapter, iii. of book I., on the judgment of the people assembled for the purpose of election, is divided into the following heads:—1. Knowledge required in the people for making a proper choice of public functionaries. 2. Will of the people in making a choice. 3. Power or means of the people to accomplish the same object. Gioja cites opinions and facts both favourable and unfavourable under each head, and then draws his own inferences—that the masses of the people are easily deceived by sophistry and false appearances; that they are led astray by those who know how to flatter their vanity and their envy against the rich; that they generally prefer rash advice to slow and discriminating counsels; that they are apt to run from one extreme to the other; that when excited by fanaticism, compassion, or fear, they become cruel and ferocious, while in quiet times they are indolent and careless, or open to bribes; that they are likely to adopt the most unjust course in the hope of having provisions cheap. He urges therefore the necessity of restricting the number of electors by means of qualifications of age, income, and civil and moral requisites. He insists chiefly on the qualification of mature age in the electors, whilst in the candidates for legislative functions he requires principally knowledge and morality, which he thinks might be ascertained by authentic documents. Book II. treats of the various kinds of rewards for the different degrees of civic merit; and he combats Bentham and Condorcet, who assert that virtue needs no reward. Gioja says in his preface, that the first idea of his subject was broached by Dragonetti, a Neapolitan writer, in 1765, in a small pamphlet, 'Della Virtù e dei Premj;' that afterwards Diderot, in his 'Essai sur le Mérite et la Vertu,' lost himself in metaphysical abstractions; and lastly, Bentham, in his 'Théorie des Peines et des Récompenses,' edited by Dumont in 1811, worked upon the idea of Dragonetti, but embraced only a small portion of the subject, and engrafted upon it several errors, which he (Gioja) refutes in his book.

Gioja's work, 'Dell' Ingiuria e dei Danni e del Soddisfacimento,' 2 vols. 8vo., 1821, is a kind of penal code, the main principle of which is compensation to the injured person. He proposes to fix a scale applicable to various cases, keeping in view chiefly the respective circumstances of the offender and of the offended. The principle of the author appears just, though the carrying of it into effect is subject to many difficulties. A good notice of the work is given in the *Biblioteca Italiana*, for December, 1821. Gioja wrote also a 'Treatise on Ideology,' 'Elements of Philosophy,' 'Il Nuovo Galateo,' or a treatise on good manners, and other works, among which the 'Filosofia della Statistica,' 2 vols. 1826-7, deserves especial mention. The first book treats of physical geography and its various branches, in which he includes climate; the second, of the population as affected by the physical character of the country; afterwards the movement of the population, its number, births, marriages, and deaths; the physical character of the people, their food, their habits and occupations; the third, of the productions of countries, vegetable, animal, and mineral. The work is highly interesting, and deserves an attentive perusal. Gioja died at Milan, in January, 1829. His remains were followed to the grave by his disciples and friends. With some eccentricities of temper, he was a most remarkable man for logical perspicuity, vastness of information, and indefatigable labour. He ranks among the very first writers on political economy that Italy has produced. (Pecchio, *Degli Economisti Italiani*; Romagnoli published a biographical notice of Gioja in the *Biblioteca Italiana*, No. 156.)

GIOJA. [COMPASS.]

GIORDA'NO, LUCA, called Luca fa presto, 1629—1705. The above dates of the birth and death of this eminent painter are those given by Velasco, which seem the most authentic; but authors differ about both dates. He was born at Naples, where he studied painting under Ribera, better known by the name of Spagnoletto. He afterwards went to Rome, where he became a pupil of Pietro da Cortona, and assisted him in many of his great works. Leaving Rome he repaired to Lombardy to study Correggio and then to Venice, to acquire a knowledge of the composition and colouring of the great Venetian artists. These various studies not only impressed on his mind a vivid idea of the style of every eminent master, but, as he had great readiness of hand, enabled him to imitate them so closely as to deceive even experienced connoisseurs. He had not only a fertile and fine imagination, but such a rapidity of execution that the number of great works executed by him is astonishing. It was not from this circumstance however that he derived the name of Fa Presto, but from the avarice of his father, who at the beginning of Luca's career sold at a high price his designs after the works of the great masters, and was continually urging him at meals as well as at work by saying 'Luca, fa presto' (Luca, make haste), which his companions gave him as a nickname. After his return to Naples he was very much employed there, till in 1679 he was invited by Charles II., king of Spain, to adorn the Escurial. He accordingly went to Madrid, where his polished manners, cheerful temper, and lively wit, in addition to his talents as an artist, gained him the favour of the court, where he remained till the death of Charles II., when he returned to his own country. His colouring was agreeable, his designs were spirited and ingenious, and his drawing, when he allowed himself time, correct; but from the rapidity with which he proceeded, his works are often deficient in the last particular. His best works are his frescoes, in the Escurial at Madrid, at Florence, and at Rome. Some of his finest pictures are at Dresden. The grand altar-piece in the Church of the Ascension at Naples, representing the Battle of the Angels and the Fall of Lucifer, is considered as one of his finest performances.

GIORGIO'NE DI CASTELFRANCO (Giorgio Barbarelli, called) one of the most distinguished artists of the Venetian school, was born in 1477 at Castelfranco, in the Trevisano. He received his education at Venice, where he at first devoted himself to music, and became an excellent performer on the lute. He however soon applied to painting, and became the disciple of Giovanni Bellini, whose minuteness of manner he speedily rejected, and adopted a much freer style, distinguished by bold fore-shortening, ample outlines, dignity and animation, breadth of drapery, richness of accompaniment, a more natural and softer gradation of tints, and forcible effects of chiaro-scuro. This last had indeed been already practised by Lionardo da Vinci, but there appears to be no solid ground for the assertion of Vasari, that Giorgione was indebted for his chiaro-scuro to some paintings or drawings by Lionardo. In the school of Bellini he had Titian for one of his fellow-pupils, who at a subsequent period of their lives was so struck with the style and colouring of Giorgione, that, as some writers affirm, he became his pupil, but it appears more probable that he cultivated an intimacy with him, which was ended by the jealousy of Giorgione, who saw that his friend was becoming a formidable rival. His greatest works were in fresco, and he adorned the fronts of many large buildings in Venice with admirable works, of which nothing now remains. He painted however many oil pictures, which are distinguished by vigorous *impasto* and fulness of pencil. His portraits, says an eminent artist, have every excellence

which mind, dignity, truth, freshness, and contrast can confer; he sometimes used ruddy sanguine tints, but on the whole they are marked by simplicity. His historical pieces are few, and as he died so young, they are of course scarce and highly valued. 'Christ allaying the Storm,' in the school of St. Mark at Venice, appears to have been the most considerable of his historical compositions. The 'Finding of Moses,' in the Archiepiscopal palace of Milan, and 'Christ bearing the Cross,' at Venice, have been looked upon as his master-pieces. He died at Venice, during the plague, in 1511, at the age of thirty-three years.

GIOTTO (properly Ambrogiotto Bondone), born in 1276, in the district of Vespignano, near Florence, was the son of a simple peasant, and followed his father's occupation. In the half idle employment of tending the sheep in the fields, he used to amuse himself by sketching figures, and being once found by Cimabue drawing a sheep with a sharp stone on a piece of slate, this artist was so struck with the performance that he asked Giotto's father to entrust his son to him. He took him to Florence, where he instructed him in painting (in fresco or distemper, oil painting not being yet discovered). Giotto applied with great diligence to the art, and fully realised the anticipation of his master, whom he soon excelled. He first freed art from the dry Gothic manner which then prevailed, and gave expression and action to his figures. He was distinguished above all his contemporaries by nobler forms, a pleasing disposition of his figures, the broad majestic folds of his draperies, and especially by a gracefulness which remained unequalled till the appearance of Masaccio. It seems likely that he was partly indebted for his superiority to the study of the antique, with which he might have become acquainted at Florence, and afterwards at Rome; and it is the more probable, as we know that he was also an architect and sculptor, and that models of his still existed in the time of Lorenzo Ghiberti. His reputation spread throughout Italy, many cities of which are adorned with his works. The greatest proof of his powers was the once celebrated mosaic of the Navicella, or boat of St. Peter, placed over the grand entrance of the church at Rome; but it has undergone so many alterations that it now affords little evidence of his talents, which however we may judge of by his still remaining works at Florence, in the coronation of the Virgin, in the church of Santa Croce, the entombment of the Virgin, at Assisi, and in the history of St. Francis, in the Sacro Convento. He may also be called the restorer of portrait painting, and has, together with the features, given the air and character of Dante, Brunetto Latini, and Donati, the first of whom mentions him in his poems. He was a man of genius and knowledge, pleasant in conversation, and fond of poetry. Boccaccio and Sacchetti often mention him in their novels, and record his witty sayings; and Petrarch speaks of him in his letters. He went with Pope Clement V. to France, where he executed many fresco paintings. He died in 1336. [CAMPANILE.]

GIO'VIO (JOVIUS) PAUL, was born in 1483, of a noble family of Como, and studied in the universities of Padua and Pavia. He was intended by his relatives for the medical profession, which however he forsook to devote himself to literature; and he applied himself to the study of the Roman classics, with a view to form his style in that language. Having repaired to Rome, soon after the election of Leo X., he found means to be introduced to him and to show him some of his compositions, and from that moment the pope became his patron. He was attached to the suite of Cardinal Giulio de'Medici, afterwards Clement VII., and followed him in various missions. He remained at the court of Rome after Clement ascended the papal throne, and witnessed the pillage of that city by the Imperial troops. After the restoration of peace, Clement bestowed on him the bishopric of Nocera, where he never resided, but entrusted the charge of his see to a coadjutor. He was present at the famous conference of Bologna between Charles V. and Clement VII., in 1530, and was favourably noticed by the emperor, who gave him a circumstantial account of his expedition to Tunis, to be inserted in the history which Giovio was then writing. When Paul III. became pope, Giovio fell into a sort of disgrace, that Pope being zealous concerning ecclesiastical discipline, in which the bishop of Nocera was a latitudinarian, both in his conduct and writings. (See his *Lettere.*) He was accused by satirical poets of every sort of licentiousness, and was also charged with infidelity and atheism. There was malignity as well as exaggeration in this, but Giovio was certainly not a pattern of clerical modesty or piety. On withdrawing to his native Como, he built himself a delightful country residence, which he fancied, though erroneously, to be on the site of one of Pliny's villas. Here he collected a museum and a gallery of portraits of the most distinguished men of his own and former ages. He spent his time partly at his villa and partly in visiting various courts of Italy, in which he was received with marked attention. He was himself a courtier by temper and habit; his conversation was humorous, and he had always some flattery ready for the great. The facetious Berni, in his 'Orlando,' has pourtrayed Giovio to the life, under the name of Feradotto, at the court of King Gradasso. In one of his visits to Florence Giovio was seized with a violent fit of the gout, of which he died in December, 1552, and was buried in the church of St. Lorenzo, where a statue was raised to his memory. He died rich, for he enjoyed several ecclesiastical benefices, besides pensions and presents from various princes.

Giovio left the following works:—1. 'Historiæ sui Temporis,' 2 vols. fol., 1550. This history is not to be trusted implicitly, for the author's pen was always at the service of his patrons and friends. 2. 'Illustrium Virorum Vitæ,' fol., 1551: a work much superior both for truth and eloquence to the first. In it the author draws the portraits of Leo X., Adrian VI., Cardinal Prospero Colonna, the Marquis Pescara, Gonsalvo of Cordova, Duke Alfonso I. of Ferrara. Blount, in his 'Censura Celebriorum Authorum,' and Thomas, in his 'Essai sur les Eloges,' highly praise Giovio's biographies. 3. 'Libellus de Piscibus Romanis.' He wrote in Italian: 4. 'Commentario delle Cose dei Turchi.' 5. 'Dialogo delle Imprese,' which is a treatise on the devices or symbols adopted by the knights in the times of chivalry, and which were the origin of our coats of arms or heraldic signs. A collection of Letters of Giovio was published after his death, 'Lettere Volgari,' 8vo., Venice, 1560. Some of his facetious epistles are found in the collection of Atanagi, Venice, 1561. His letters contain much literary and historical information concerning that age, and are worthy of perusal. One of his descendants, who died in our time, Count Giovan Battista Giovio, has written a copious panegyrical notice of Paolo Giovio.

GIPSIES, a word corrupted from Egyptians, is the name given in England to a wandering race of people who are found scattered over many countries of Europe, whither they migrated from the East about the beginning of the fifteenth century. Pasquier, in his 'Recherches Historiques,' says that they first appeared at Paris in the character of penitents, or pilgrims, in August, 1427, in a troop of more than 100, under some chiefs who styled themselves counts, and that they represented themselves as Christians driven out of Egypt by the Mussulmans. They obtained permission to remain in the kingdom; other troops followed, and they wandered about in all directions, unmolested for many years, committing petty depredations, and their women assuming the calling of fortune-tellers. In 1560 an ordonnance of the states of Orléans enjoined all impostors and vagabonds styled 'Bohemians,' or 'Egyptians,' to quit the kingdom under pain of the galleys. The name of Bohemians, given to them by the French, may be owing to the circumstance of some of them having come to France from Bohemia, for they are mentioned as having appeared in various parts of Germany previous to their entering France: others derive the word from 'Boëm,' an old French word signifying a sorcerer. (Moreri, art. *Bohemiens*; and Ducange's 'Glossary,' art. *Ægyptiaci*.) The Germans gave them the name of 'Zigeuner,' or wanderers; the Dutch called them 'Heiden,' or heathens; the Danes and Swedes 'Tartars.' In Italy they are called 'Zingari;' in Turkey and the Levant 'Tchingenes;' in Spain they are called 'Gitanos;' in Hungary and Transylvania, where they are very numerous, they are called 'Pharaoh Nepek,' or 'Pharaoh's people.' The notion of their being Egyptians is probably derived from the circumstance that many of them came immediately from Egypt into Europe, but it seems proved that they are not originally from that country, their appearance, manners, and language being totally different from those of either the Copts or Fellahs. There are many gipsies now in Egypt, but they are looked upon as strangers, as indeed they are everywhere else.

It is now generally believed that the gipsies migrated originally from India at the time of the great Mohammedan invasion of Timur Beg; that in their own country they belonged to one of the lowest castes, which resemble them in their appearance, habits, and especially in their fondness

for carrion and other unclean food. Pottinger, in his 'Travels,' saw some tribes resembling them in Beloochistan. There is a tribe near the mouths of the Indus called Tchinganes.

The gipsies, in their language, call themselves Sind; and their language has been found to resemble some of the dialects of India. (*Bombay Transactions*, 1820.) They have no traditions or records concerning their origin; no religion of their own, but they adopt the outward forms of the people among whom they live, whether Christians or Mussulmans. Everywhere they exhibit the same roving habits, a dislike to a fixed settlement and to the arts of husbandry, uncleanness in their food, licentiousness, ignorance and intellectual apathy, a disposition to pilfer, and to impose on the credulity of others. They seldom commit violent robbery or other heinous crimes, being fearful of punishment. Maria Theresa ordered those in her states to be instructed in agriculture, with a view to their permanent settlement; but her endeavours were not very successful. In Hungary and Transylvania however many of them follow some regular trade and have fixed habitations; they wash gold from the sand of the rivers, and they work iron or copper; some are carpenters and turners, others are horse-dealers, and even keep wine-shops or public-houses. They abound in Wallachia, Moldavia, and Bessarabia, and they are found in Russia as far as Tobolsk. Grellman, in his 'Versuch über die Zigeuner,' Göttingen, 1787, conjectures that there are between 700,000 and 800,000 in Europe, of whom 40,000 are in Spain, chiefly in the southern provinces. In England they have much diminished of late years in consequence of the inclosure of land and the laws against vagrants. J. Hoyland has collected the most accurate information that could be procured concerning this strange race, in his *Historical Survey of the Customs, Habits, and present State of the Gypsies; designed to develop the Origin of this Singular People, and to promote the Amelioration of their Condition*, 8vo., York, 1816. He has largely made use of the work of Grellman.

GIRAFFE, CAMELOPA'RDALIS (*Giraffa* of Brisson, Camelopard of Pennant and authors), a genus of Ruminants, with persistent horns common to both sexes, comprising the tallest of the known quadrupeds.

Organization.

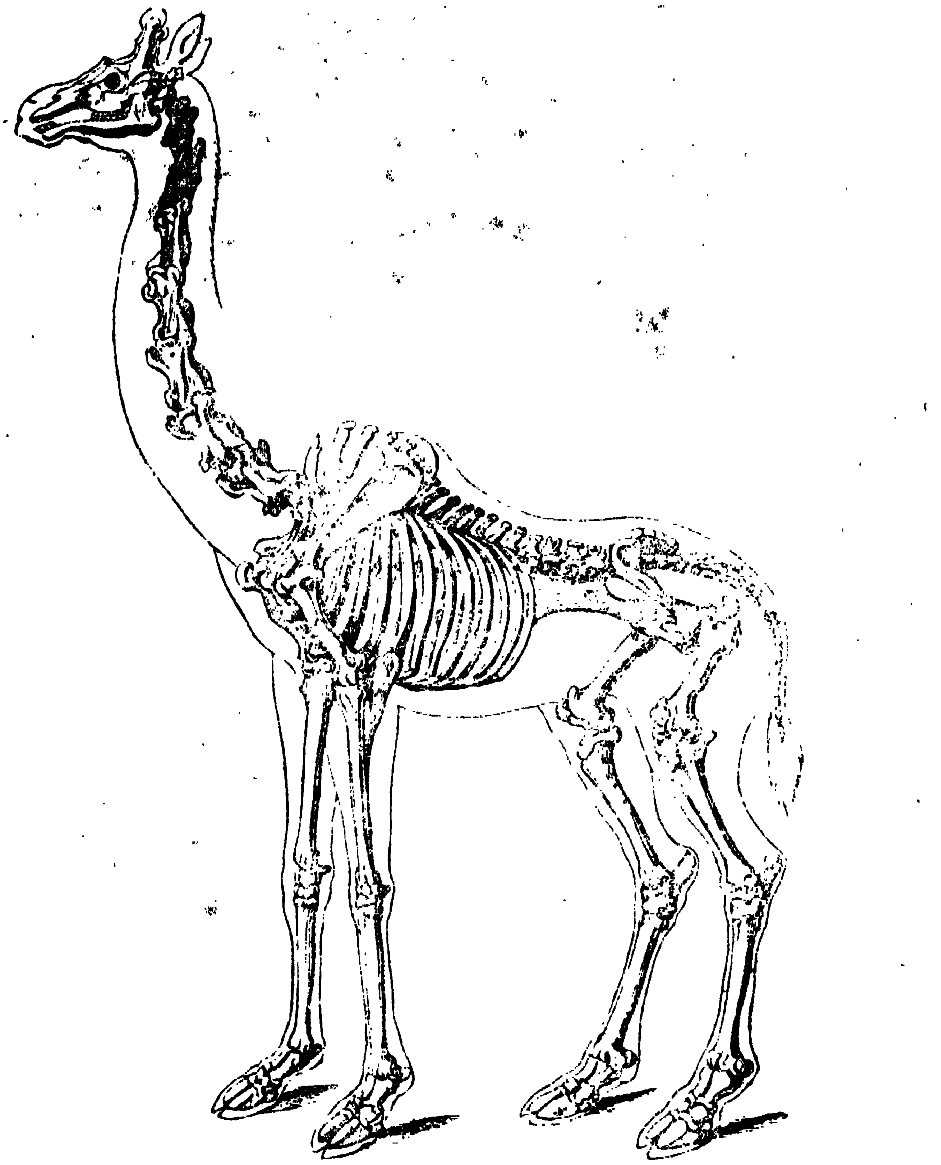
The skeleton of a Giraffe arrests the attention of the observer at once:—the head lifted on high upon the extremely elongated neck, the high withers, and the slender length of limb, taken together contrast strangely with the bony fabrics of the other quadrupeds. A man who looks up at such a skeleton for the first time, and without previous knowledge of its structure, must be struck at finding that the towering neck consists of exactly the same number of bones that form his own. The skull is light and thin. The horns are considered by Dr. Rüppell (who, during his travels in Northern Africa, obtained in Nubia and Kordofan three specimens, two males and one female) as constituting the principal generic character, they being formed by distinct bones, united to the frontal and parietal bones by a very obvious suture, and exhibiting throughout the same structure as the other bones. In both sexes, he observes, one of these abnormal bones is situated on each branch of the coronal suture, and the male possesses an additional one, placed more anteriorly and occupying the middle of the frontal suture. The existence of this third appendage is considered to furnish a complete refutation of Camper's theory with regard to the *Unicorn*, viz. that such an occurrence is contrary to nature, and to prove at least the possibility of the existence of such an animal. This appendage is conspicuous in the plate containing the crania (*Atlas zu der Reise im Nördlichen Afrika*, von Eduard Rüppell,—Pl. 9, fig. *a, a*), and, as it is there represented, rises abruptly from the os frontis with all the appearance of a third horn. Cuvier, in his last edition of the 'Règne Animal' (1829), follows Dr. Rüppell, and, speaking of the horns, says, their bony core (noyau osseux) is articulated in youth by a suture on the frontal bone. In the middle of the chanfrein is a tubercle, or a third horn, larger and much shorter but equally articulated by suture.

The well-known accuracy of Dr. Rüppell demands every degree of respect; and if the figure alluded to be a correct representation of the ordinary state of the adult Nubian male Giraffe, and not an accidental deformity, the third

Skull of male Giraffe, from Rüppell's figure.

horn would form a good ground for specific distinction. There are skulls of the Cape Giraffe, both male and female, in the Museum of the College of Surgeons; and that of the male, which is an adult with the persistent teeth, has no such horn; but there is a considerable gradually-rising protuberance, which is more strongly developed than the same part in the female cranium. In all the crania which we have seen, and in all the living specimens, the females possess this protuberance as well as the males, though not in so high a degree of development; and the true horns, at least the bony cores, are much larger in the male than in the female. It may be said that the living and dead specimens which we have lately received from North Africa are comparatively young; though some of them are not so very young. The three Giraffes now (1838) living in the garden of the Zoological Society at the Regent's Park are advancing fast towards their full growth, and in all of them the protuberance will be seen; though that of the female is not quite so highly marked perhaps as those of the males. But Mr. Owen, in his paper read before the Zoological Society of London on the 23rd of January, 1838, wherein he entered into the highly interesting details which the dissection of three Nubian Giraffes* had enabled him to demonstrate, shows that this middle protuberance arising from the head is not a true horn, articulated by a suture; but merely a thickening of the os frontis. This position Mr. Owen is enabled to lay down from the section of the skull of a male (Northern) Giraffe, and from the examination of various crania of both Nubian and Cape (male and female) old and young Giraffes. There appears to be no evidence to lead to the conclusion that there is anything at any time in this part of the structure naturally, that can be considered more than a mere frontal protuberance occasioned by the thickening of the bone, a protuberance which will not separate upon maceration, as the two horns will, in the young animal at least. The lightness of the cranium is owing in great measure to the sinuses, which are minutely described by Mr. Owen in his paper; these run along the whole upper part of the cranium, and the occiput is raised by their extension. Mr. Owen shows that a principal object of these sinuses is to increase the surface of the attachment of the ligament supporting the head, and draws attention to the remarkable vertical extension of the condyles of the occiput, a structure which enables the animal to tilt its head back, and gracefully and easily to raise it till it is on a line with the neck. The reader will find the section of the head above alluded to in the Museum of the Royal College of Surgeons, numbered 965 (Osteological Series). In the same museum he will find entire crania of the Cape Giraffe (male and female), with other detached bony parts, and the most perfect and beautiful skeleton of the Nubian Giraffe we have ever seen, though it is that of a comparatively young animal. The position and appearance of the elastic cartilages on the posterior edges of the scapulæ are here exhibited, a beautiful provision for the easy springy carriage of the body, which is principally suspended from the muscles there attached, and slung as it were between these points and the sternal and lumbar regions. In the British Museum are two crania presented by Mr. Burchell. The next best skeleton of a Giraffe known to us in this country is that in the museum of the Zoological Society of London, prepared from the individual which was in the possession of King George IV. at Windsor.

* Two males and one female; all with deciduous teeth.



f Giraffe; the curved outline from the posterior edge of the scapula shows the position of the elastic cartilage above alluded to.

Mr. Owen found the ligamentum nuchæ immense, consisting of two bilateral moieties; it commences at the sacrum, gains fresh accessions from each dorsal vetebra, the spines of which are remarkably elongated for that purpose, is inserted into all the cervical vertebræ, with the exception of the atlas, and attached to the extended surfaces of the occipital region of the skull produced by the organization above alluded to. Before we proceed to notice the softer parts we must refer to the dentition, which offers the same formula as that charcteristic of the deer, goat, antelope, sheep, and ox, viz., incisives $\frac{0}{8}$, canines 0, molars $\frac{6-6}{6-6} = 32$. In the 'Nova Acta Physico-medica Academiæ Cæsareæ Leopoldino-Carolinæ Naturæ Curiosorum,' tom. xii., part 1, is a paper by Dr. D'Alton on the teeth of the Giraffe, written, it should seem, principally with a view to correct the notion apparently entertained by Dr. Bojanus in a preceding paper in the same part, not only that the dentition of the Merycotherium has certain points indicatory of that animal being intermediate between the camels and the sheep, 'camelinum inter et ovillum genus,' but that it might possibly be the Giraffe. Dr. D'Alton figures the teeth of the latter, and shows, by a comparison with those of the Merycotherium, their discrepancy both in size and structure from those of the fossil animal.

The tongue of the Giraffes requires particular notice. Sir Everard Home remarks, that besides being the organ of taste, it has many properties of the proboscis of the elephant, one being an elongation of the organ of smell, the other of taste. The proboscis is incapable of elongation, he observes, beyond one inch in extent, in consequence of its cartilaginous tubes; while the tongue may be extended to seventeen inches after death, and can in the living body lie so diminished in size as to be inclosed within the animal's mouth.

Some mechanism, he remarks, must exist by which this elongation may be performed, as in the tongue of the reindeer: but he states that a post mortem examination would be necessary to decide this. He notices the organ as being very smooth; that is, it is smooth when the papillæ are not raised, as they can be at pleasure, but rougher when they are, and slightly adhesive: it is spotted, but the sp[ots are] not raised, and there is a black rete mucosum, to prevent, as he thinks, the surface from being blistered by exposure to the sun. 'In the absence of an opportunity,' continues Sir Everard, 'of examining the internal structure of the Xariffa's tongue after death, I was led to the opinion that the change of size is effected by the organ containing a reservoir, out of the course of the circulation, which can be filled with blood at the will of the animal, so as to give it rigidity, and enable it to extend itself for the performance of the different actions in which it is employed with the smallest possible degree of muscular exertion. It occurred to me at the same time, that whatever construction may be the means by which the Xariffa's tongue is able to apply itself to such various purposes, whether that which appeared to me probable, or any other, something similar would be met with in other animals, particularly in the tongue of the deer, which, after death, readily admits of being drawn out to the extent of eight inches, although when immersed in rectified spirits it contracts to five inches. For the purpose of such an examination, a deer's tongue, recently after the animal's

death, was injected with minute red injection, so as to distend the arteries and show the course of the circulation in them to the greatest advantage. This tongue was afterwards divided longitudinally in a perpendicular direction, also in a horizontal one, to show the muscles of which it is composed, as well as the other parts that it contained.' From this examination, the structure of the tongue of quadrupeds in general is described by Sir Everard as being longitudinally divided into two equal portions by a middle line; the muscular structure occupies the whole of the interior substance, receiving a large supply of nerves and blood-vessels from a lateral nerve and artery that pass along the outer edge; these are imbedded in a very loose cellular tissue, the texture of which admits of the blood-vessels being distended to a very great degree, so as to enlarge the volume of the tongue; and beyond this tissue, surrounding and forming a case for the whole of the upper and lateral part of the organ, is a strong very elastic covering of some thickness, which yields when the muscles and the trunks of the arteries are distended with blood, so as to give both extent and rigidity to the organ, and admit of the different actions in which it is employed. Sir Everard then adds, that there can be no doubt of the structure of the Xariffa's tongue being the same; its actions depending upon the combined powers of muscular contraction and elasticity; its increase and diminution of size arising from the blood-vessels being at one time loaded with blood and at another empty.

The chief modification in the muscles of the tongue is in those destined to retract it. Mr. Owen, in a note to his edition of 'Hunter's Animal Œconomy' (8vo., London, 1837), says, 'a most beautiful and forcible example of the use of tendon in limiting the length of a muscle to the extent of motion required to be produced in the part to be moved occurs in the sterno-thyroidei of the Giraffe. Had these muscles been continued fleshy as usual from their origin, through the whole length of the neck to their insertion, it is obvious that a great proportion of the muscular fibres would have been useless, because such a condition of the muscle would have been equal to have drawn down the larynx and os hyoides more than one-third of the extent of the neck, which is neither required nor permitted by the mechanical attachments of the parts. The sterno-thyroidei therefore proceed from the head of the sternum blended together in one fleshy fasciculus for about nine inches, and end in a tendon which is continued for six inches; this then divides, and the muscles proceed again fleshy for about sixteen inches, when a second tendon intervenes in each between the preceding and the next fleshy portion, which is finally inserted into the thyroid cartilage, and, by a continued fascia into the os hyoides: thus the quantity of contractile fibre is proportioned to the required extent of motion by intervening tendons; the sterno-hyoidei being wanting, or their place supplied by the sterno-thyroidei, as in some other ruminants. The analogue of the omo-hyoideus is in the same animal adjusted to its office by a different and more simple modification; its origin is removed from the shoulder-blade to the nearest point (the third cervical vertebra), from which it could act with the requisite force and extent upon the os hyoides.

Sir Everard Home fancied that the Giraffe on which he made his observations, the individual belonging to George IV., preferred licking the hand of a lady to that of a man. Mr. Davis, who saw a great deal of the animal, never observed this. It may be easily believed that the animal distinguished the fair hand from which it received gifts and attention; but certainly the Giraffes in the Zoological Garden at the Regent's Park exhibit no such preference. They appear to use their tongues generally as organs of examination, and the power of prehension is so great that we have seen the tongue, when extended to the utmost, grasp an ordinary lump of sugar, of which the animals seem very fond, and convey it into the mouth. We have also observed the Giraffes retrovert the tongue for the purpose of cleaning the nostrils, an office which its flexibility enables it to perform in the most perfect manner. The utility of such a power of prehension and extension to an animal whose principal food consists of the leaves and slender twigs of trees is manifest. Mr. Davis says that the tongue can be so tapered as to enter the ring of a very small key.

With regard to the stomach and digestive organs generally, the Giraffe, it is true, wants the receptacle for water which the camel and dromedary possess. There are no water-cells belonging to the rumen as there are in the Camelidæ; and this part of the structure is, as Mr. Owen points out, fashioned according to the horned ruminant

Head of Giraff (Nubian) with the tong elongated.

Head of Giraffe (profile), showing the frontal protuberance and the mane (Nubian).

type. But he also shows that the reticulum is not, as stated by Sir Everard Home, 'destitute of the cellular structure met with in other ruminants,'* but that it has cells, though very shallow ones, as in the rein-deer. Mr. Owen further states that the coils of the colon in the Giraffe are spiral, as they are in the deer and in the antelopes; and that like them it has a simple cæcum, which is 2 feet 2 inches in length. The first Giraffe (female) dissected by Mr. Owen had a double gall-bladder, each bladder of the usual size: this is preserved in spirit in the museum of the College. The other two Giraffes (males) were without a trace of gall-bladder. He believes therefore that absence of the gall-bladder, as in the deer (the antelopes have it), is the rule.

The kidneys in the Giraffes examined by Mr. Owen were not lobulated as in the ox, but simple, as in the deer and antelope.

* Abstracts of 'Phil. Trans.,' vol. ii., p. 389.

Mr. Owen found the male organs to agree with the horned ruminant type; that is, the prostate is divided, not single as in the camel. There is a peculiarity in the termination of the urethra; for it is continued as a membranous canal, one inch and a half beyond the extremity of the glans, adhering to the prepuce. The female organs differ also from those of the camels, and agree with those of the true ruminants, exhibiting processes for the cotyledons in the interior of the cornua.

These are the principal observations made by Mr. Owen in his interesting paper, but he also notices one beautiful provision in the structure of the animal which we must not omit. The nostrils of the Giraffe are provided with cutaneous sphincter muscles, and can be shut at will like the eyes. Mr. Owen supposes that the object of this mechanism is to keep out the sand when the storms of the desert arise.

Every one must be struck with the beautiful large eye of the Giraffe; but he will find upon further examination that it is so prominent and so placed that the animal can see much of what is passing on all sides, even behind it, without turning the head. Thus it is approached with the greatest difficulty; and, if surprised, or run down, it can direct the rapid storm of kicks by which it defends itself in the most accurate manner. We need hardly add that the horny hoofs are divided, and that the two small lateral toes generally seen in the true ruminants are wanting.

Natural History, Systematic Arrangement, &c.

In Deut., c. xiv., where there is an enumeration of meats, clean and unclean, we find (verse 5), among the beasts which the Israelites are permitted to eat, 'the hart, and the roebuck, and the fallow deer, and the wild goat, and the pygarg, and the wild ox, and the *chamois*.' So it stands, or with very slight variation, in the more modern English translations. In the black-letter Bible 'imprinted at London by Robert Barker, printer to the king's most excellent majestie (1615),' we find the same verse thus written: 'The hart, and the roebucke, and the bugle,* and the wilde goate, and the unicorne, and the wild oxe, and the *chamois*.' In the *Physica Sacra*, the verse is thus given in Latin:—'Cervum, Capream, Ibicem, (*a*) Hircocervum, '(*b*) Unicornem, Urum et *Tarandum*;' and a note adds, (*a*) Alii legunt Bubalum aut Bovem Sylvestrem. (*b*) Tragelaphum.' Opposite to this stands the following version of the same: 'Cervum et Capream, Bubalum, Tragelaphum, Pygargum, Orygem, *Camelopardalum*.' These are the Tigurine and Vulgate versions. The original word, it appears, is זֶמֶר, *Zemer*, and Scheuchzer observes that Hieronymus, many interpreters, and many versions render the word by *Camelopardalis*, which is the *Zurapha*, *Zerafet*, and *Zürafet* (plur. *Zerafi* and *Zeraif*) of the Arabians; *Sürnapa*, *Zürnapa*, *Zürnepa*, of the Turks; an interpretation which renders the Arabians and Jews doubtful whether the flesh, which is said to be hard and difficult of digestion, be permitted by the law. Bochart rejects the term *Camelopardalis*, because that animal is not an inhabitant of either Arabia or Palestine, but of Nubia and Æthiopia, and therefore was long unknown to Europeans. Scheuchzer adds that Aristotle says nothing about the Camelopard or Cameleopard—'de eâ nil prorsus habet Aristoteles'—and that the first of the Greeks who described it was Agatharchides, who lived in the time of the sixth Ptolemy (Philometor). This animal, he continues, was not seen at Rome before the time of Cæsar: 'Unde inferre licet, non ignotam fuisse duntaxat Mosis tempore, sed et Alexandri, qui Mose posterior est annis 1200.' Wherefore the commentator has recourse to the Cervine or Caprine genus, and selects the *Rupicapra* (Chamois), observing that 'our two versions' read *Tarandum* (the Reindeer, which, he says, in Meninzk. Lex. has the cognomen of *Sürnapa* and *Giraffa*). In Scheuchzer's plate (cccxxix.) of the clean and unclean animals (*Levit.*, c. xi., v. 2), the Giraffe does not appear, but at pl. cccxli. (*Deut.*, c. xiv., v. 5), he figures a '*Camelopardalis*' and '*Tarandus*'—'Cameel-Pardel' and 'Rennthier,' the former with sharp antelope-like horns, and the latter with a spotted skin and somewhat extraordinary antlers. With the exception of the head and horns, that part of the Camelopard which appears—the hind-quarters are hidden by the other figure—is not bad. Both figures appear to be copies from Jonston, who seems to have copied one of his Camelopards from Gesner. Scheuchzer introduces the body and head of a Camelopard with the same antelope-like horns, but rather more curved, in the back-ground of pl. xxxii. (*Gen.*, c. iii., v. 21.*) The commentator in the 'Pictorial Bible,' where a good cut of the Giraffe is given, says, with reference to the word *chamois*, 'The Arabic version understood that the Giraffe was meant here, which is very likely to have been the case; for the chamois is not met so far to the southward as Egypt and Palestine. The giraffe or cameleopard (*Camelopardalis Giraffa*) is a singular as well as beautiful creature found in the central parts of Africa. The Jews had probably many opportunities of becoming acquainted with the animal while in Egypt, as had also the Seventy, who resided there, and who indicate it in their translation of the Hebrew name.'†

Belzoni notices the Camelopard on the wall of the sekos of the Memnonium, and on the back of the temple of Erments. In Gau's 'Nubien' (pl. 15) is the representation of a relief, for the general character of which we refer to the work itself, and to the interesting account published in the 'Library of Entertaining Knowledge: British Museum—Egyptian Antiquities,' vol. i. In the procession appears, among other animals, a well-executed figure of a Giraffe led by a man dressed in skins. The author of the useful and amusing book last quoted supposes the relief to represent the booty obtained after a victory.

Rosellini, in his great work on Egypt, gives the coloured engraving of a *Pompa*, wherein a Giraffe (*M. C.*, No. xxii., Fig. 2), the spots on which are very close, is depicted as led by two men, who hold cords tied to the fore-legs below what is called, in common parlance, the knee. A green monkey with a red face, &c., and a long tail, is climbing up the Giraffe's neck. The subligacula of the leaders, who appear to be Nubians (?), are different; those of the one are spotted like a leopard-skin, and this man has a dark blue close cap on his head; those of the other show a sort of reticulated pattern, and he wears a close cap with a light ground and light blue spots. And here it is worthy of note that we find in the enumeration of the rare animals exhibited in the Pompa of Ptolemy Philadelphus at Alexandria, described in so lively a manner by one of the Deipnosophists (Athenæus, lib. v., c. 8, s. 32,) one Camelopard—*καμηλοπάρδαλις μία*.

Whether the *ἱππάρδιος* (Hippardius—Horse-pard) of Aristotle (lib. ii., c. 1) be the Giraffe appears to be doubtful, and the prevailing opinion seems to be that he meant by the word some species of Deer. The passage which mentions the *ἱππέλαφος* (Hippelaphus—Horse-stag or Horse-deer)‡ states that both these animals have cloven feet and the head armed with horns, but that the female of the Hippelaphus has no horns; thereby intimating that the female of the Hippardius had. This however would be equally applicable to the rein-deer.

The celebrated Prænestine pavement, said to have been made by the direction of Sylla, who had held the office of quæstor in Numidia, represents the Giraffe both grazing and browzing, and it seems to be a good opinion that the artists employed to work in mosaic even in Italy and Spain were Egyptian Greeks. Still the animal itself does not appear to have been seen in Italy before the time of Julius Cæsar, who exhibited it among other animals in the Circensian games.§

In his description Pliny appears to have taken the darker parts of the skin of the animal as forming the ground colour, and relieved by the lighter tint. This is probably the same animal as that mentioned by Varro, who alludes to a *Camelopardalis*, as having been lately brought from Alexandria, in figure like a camel and spotted like a panther. The Giraffe afterwards became a not unfrequent and conspicuous part of the Roman shows. Thus the third Gordian had ten at one time. We trace the animal in the

* See the note to Bison, vol. iv, p. 462

* 'And unto Adam also and to his wife did the Lord God make coats of skins and clothed them.'

† It should be remembered however that the law above alluded to was given to the Israelites after their departure from Egypt, and when they were in Palestine, where they were not likely to see the animal, much less eat it.

‡ Mr. Ogilby says (*Zool. Proc.* 1836) that Tragelaphus Hippelaphus (Antilope Picta of authors), the Nylghau (Antelope, vol. ii. p. 75) or Neel-ghae, and not the Saumer Deer of India, is the animal described by Aristotle under the name of Hippelaphus.

§ 'Nabin (Pliny, lib viii., c. 18) Æthiopes vocant, collo similem equo, pedibus et cruribus bovi, camelo capite, albis maculis rutilum colorem distinguentibus, unde appellata Camelopardalis, dictatoris Cæsaris Circensibus ludis primum visa Romæ. Ex eo subinde cernitur, aspectu magis quam feritate conspicua: quare etiam ovis feræ nomen invenit.'

writings of Artemidorus, Strabo, Oppian, Heliodorus, and others, till the great blank of literature intervenes.

After the revival of letters, we find in Belon a good description upon the whole, and a very tolerable figure. In the small 4to. intituled 'Portraits d'Oyseaux, Animaux, Serpens, Arbres, Hommes et Femmes d'Arabie et Eg observez par P. Belon du Mans, le tout enrichy de (trains, pour plus facile cognoissance des Oyseaux, et autres Portraits' (1557), the figure is given with only the following notice and quatrain above and below it:—'Portrait de la Giraffe, nommée en Latin, Camelopardalis: les Arabes l'appellent Zurnapa.' The quatrain is

> 'Belles de corps les Giraffes, et doulces,
> Ont en maintien du Chameau la maniere.
> Leurs pieds sont haults devant et bas derriere;
> Poil blanc et roux; cornes courtes et mousses.'

Gillius states that he saw three at Cairo, and gives a description of the animal. Prosper Alpinus relates that he saw a *Camelopardalis*, 'quem Arabes *Zurnap*, et nostri Giraffam appellant,' and likens it to a very elegant small horse.

Gesner, who, among other synonyms, enumerates *Giraffa* (alias *Gyrapha, Girapha*) as the name of the *Camelopardalis*, or *Camelopardus*, or *Camelus Indica*, gives also *Zirafa*, as well as *Nabis* (Æthiopian), *Girnaffa* (Persian), and *Serapha* (Arabian). His figure, which, he says, is taken from an Italian printed book, by an anonymous author, is evidently made up principally from the descriptions of the antients. It has antelope-like subrecurved sharp horns, and a short sharp-pointed tail with something of an upward curve, in which may be traced the 'caudam Dorcalidis, id est Capreoli,' as the text has it, attributed to the animal by Oppian. In the *Additiones* (Icones, &c.) is presented a much better figure, as far as the horns are concerned, but with a neck, and of a height, generally, out of all proportion. The drawing is said to have been diligently taken at Constantinople, where the animal had been sent as a present to the emperor of the Turks, and transmitted to friend in Germany, A.D. 1559. The figure is without spots.

Aldrovandus gives a figure of the animal with its elongated tongue protruded and browzing upon a tree, which, awkward though it be, would be not very far wrong, were it not for the flowing mane and little sharp horns with a curve forwards.

Jonston gives no less than five figures, three with and two without spots, some with and some without manes, under the names of *Camelopardus*, *Camelopardalis*, *Gierafra*, and *Cameli Indici*, but all with sharp horns of various degrees of curvature, besides two long-necked hornless spotted quadrupeds, one designated as *Camelus Indicus versicolor*, the other as *alius Camelus*.

It is not to be wondered at that some of the figures and descriptions given by such writers as the author last quoted cast a doubt upon the very existence of the animal, and it may not be uninteresting, before we proceed to the later writers on the natural history of this extraordinary animal, to note some of the other evidences preserved in old or uncommon books. In the 'Historia del Grand Tamerlane,' (Madrid, 1782), 'The ambassadors sent by the king of Castile, Henry III. (1403—2nd embassy) to the great Tamerlane, arrived at a town called Hoy, now Khoy, on the confines of Armenia, where the Persian empire commences. At that town they fell in with an ambassador whom the sultan of Babylon had sent to Tamerlane. He had with him as many as twenty horsemen and fifteen camels, laden with presents which the sultan sent to Tamerlane. Besides these, there were six ostriches, and an animal called *jornufa* (giraffe), which animal was formed in the following manner:—In body it was of the size of a horse, with the neck very long, and the fore-legs much taller than the hinder ones; the hoof was cloven like that of the ox. From the hoof of the fore-leg to the top of the shoulder it was sixteen hands (palmos); and from the shoulders to the head sixteen hands more; and when it raised its neck it lifted its head so high as to be a wonder to all. The neck was thin like that of the stag; and so great was the disproportion of the length of the hinder legs to that of the fore-legs, that one who was not acquainted with it would think it was sitting, although it was standing. It had the haunches slanting like the buffalo, and a white belly. The skin was of a golden hue and marked with large round white spots. In the lower part of the face it resembled the deer; on the forehead it had a high and pointed prominence; very large and round eyes; and the ears like those of a horse; near the ears two small round horns, the greater part covered with hair, resembling the horns of deer on their first appearance. Such was the length of the neck, and the animal raised its head so high when he chose, that he could eat with facility from the top of a lofty wall; and from the top of a high tree it could reach to eat the leaves, of which it devoured great quantities. So that altogether it was a marvellous sight to one who had never seen such an animal before.'*

In the 'Principal Occurrents in John Leo (Leo Africanus) his Ninth Booke of the Historie of Africa,' (Purchas, lib. vi., c. 1 sec. 9,) we find among the animals of Ethiopia 'The giraffa, so savage and wild, that it is a very rare matter to see any of them; for they hide themselves among the deserts and woods where no other beasts use to come; and so soon as one of them espieth a man, it flieth forthwith, though not very swiftly. It is headed like a camell, eared like an oxe, and footed like a † ; neither are any taken by hunters but when they are very young.' In the index of the same book we find 'Camelopardalis, a huge wilde beast;' and a reference to page 1183, where we find (Purchas, lib. vii. c. 8, s. 2) in the same paragraph, where mention is made of the Abassine soil (Abassia, from Fernandez), this sentence:—'Hares, goats, harts, bores, elephants, camels, buffals, lions, panthers, tigres, rhinocerotes, and other creatures, are there seene, and one so huge that a man sitting on horsebacke may passe uprighte under his belly; his shape is like a camell, but his nature divers, feeding on leaves which he reacheth from the tops of trees with his necke stretched forth.' In the margin is printed, 'This seemeth to be the Camelopardalis;' and indeed the description will do very well for it, with the exception of the horse and his rider passing 'upright under his belly.'

Again, in the fifth volume, 'The sixt booke, chap. i., of Africa, and the creatures therein,' and s. 2, 'Of the beasts, wild and tame,' is mentioned 'The *Giraffa*, or *Camelopardalis*, a beast not often seene, yet very tame, and of a strange composition, mixed of a libard, hart, buffe, and camell, and by reason of his long legs before, and shorter behinde, not able to graze without difficultie, but with his high head, which he can stretch forth halfe a pike's length in height, feeds on the leaves and boughs of trees.'

In a note is added, 'P. Bellon, lib. ii., c. 49, doth largely describe him. (See his description in Moreson and Sandys. Also Master Sanderson saw one at Cairo, and hath described him in his 'Voyage,' which I have printed.' (Tom. i. lib. 9.) Upon turning to the passage (lib. ix., c. 16, s. 2) it appears that Sanderson saw the animal at Constantinople. 'The admirablest and fairest beast that ever I saw was a Jarraff, as tame as a domesticall deere, and of a reddish deere colour, white brested, and cloven-footed; he was of a very great height, his fore legges longer than the hinder, a very long necke, and headed like a camell, except two stumpes of horne on his head. This fairest animall was sent out of Ethiopia to this Great Turke's father for a present; two Turkes, the keepers of him, would make him kneele, but not before any Christian for any money. An elephant that stood where this faire beast was, the keepers would make to stand with all his four legges, his feet close together upon a round stone, and alike to us to bend his fore legges.'‡

In the 'Museum Tradescantianum' (1656), at the end of the second section, 'Four-footed beasts, with some hides, hornes, hoofes,' we find 'divers horns answering to those by authors, attributed to the ibex, gazella, hippelaphus, tragelaphus, cervus palmatus, camelopardalis, &c.'

In Ludolf's 'Æthiopia,' of which there is a curious translation 'made English by J. P. Gent' (1682), the following paragraph appears in the chapter 'of four-footed beasts.' 'The next is the *Camelo-pardalis*, or Panther-camel, which is not' (as big) 'and bulkie as the elephant, but far exceeds him in tallness. For this beast is so very

† Here there is a word wanting in the original.

‡ c. xvi.

'By the permission of Almightie God,

'Sundrie the personall voyages performed by John Sanderson, of London, merchant, begun in October, 1584, ended in October, 1602, with an historicall description of Constantinople.' The second voyage to Constantinople appears to have commenced in 1591, and Sanderson arrived there on Palm-Sunday, 'where,' says he, 'then I remained sixe or seven yeeres, in which time I had the view of many animals.' After enumerating some, he commences the paragraph which we have above given.

high that a man of a just statue (stature) reaches but up to his knees, so that it seems very credible what is reported, that a man on horseback, sitting upright on his saddle, may ride under his belly. He derives his name from hence, that he has a long head and a long neck like a camel, but a skin spotted all over like a panther. The Romans, when they first beheld this beast, called it a wild sheep, tho being more remarkable for its aspect then (than) its wildness or fierceness, as we read in Pliny. By the Abissines, by reason of the smallness of his tayl, he is called Jeratakacin, that is *Slender Tayl*; by the Italians Giraffa, from the Arabian word *Zucaffa* (Zuraffa?).'

Hasselquist, who travelled in the years 1749-50-51-52, mentions, in his 'Voyages and Travels,' the *Cervus Camelopardalis.* The camel-deer, Bellon., Camelopardalis Giraffa, Alpin., Ægypt, Zurnap, Arab. 'The colour of the whole body, head, and legs of this animal is variegated,' says the traveller, 'with dark brown spots; the spots are as large as the palm of a man's hand, of an irregular figure, and in the living animal are of various shades. This deer is of the bigness of a small camel; the whole length from the upper lip to the tail is twenty-four spans. It is met with in the shady and thick woods of Senaar and Æthiopia. N.B. This is a most elegant and docile animal; it has been seen by very few natural historians, and indeed scarcely by any except Bellonius; but none have given a perfect description or good figure of it. I have only seen the skin of the animal, and have not yet had an opportunity of beholding it alive.' In the 'Act Upsal.' the same zoologist gives a very minute description of the animal.

Brisson gave it a generic station, under the name of Giraffa, in the first section of his fifth order, consisting of those quadrupeds which have no incisor teeth in the upper jaw, but eight in the lower, and the hoof divided. This first section contains those genera which have simple horns; and, besides the Giraffe, comprises the goats, the sheep, and the oxen.

Our countryman John Ray placed the Giraffe under his *Cervinum genus*, the fourth of his ruminants, with the deer, as the title implies.

Linnæus, in the last edition of his 'Systema Naturæ,' (1766), gives the Giraffe as the first species of his genus *Cervus*, or *Cervus Camelopardalis*, and describes it as being a cervus with very simple horns, and the fore-legs, or feet, longest. 'C. cornibus simplicissimis, pedibus anticis longissimis.' The 'habitat' he gives as Æthiopia and Senaar, and adds, that the animal even then was obscure, and that it is sprinkled with white spots like fawns: 'Animal etiamnunc obscurum, adspersum maculis albis, ut cervi juniores.' He alludes to its grazing with divaricated legs, but says that its principal food consists of the leaves of trees.

A drawing, which appears to have been a mere rude sketch, nothing worth, together with a notice of the Giraffe, was brought under the observation of the Académie des Sciences (1764). This drawing and notice related to one of these animals which had been found during a journey made in 1762, as far as two hundred leagues northward of the Cape of Good Hope. Buffon notices this as extending the geographical distribution of the Giraffe, which had been confined to Æthiopia by Thevenot and the majority of writers; but this is the principal contribution to the history of the animal in the Count's article, which is indeed learned and eloquent, but erroneous in many points, and unnecessarily severe on Hasselquist for the dryness and imperfection of his description. Buffon gives the description of the Swedish naturalist in a note, and though there may be some obscurity in the part relating to the horns when read by one who had never seen the animal—and of this Buffon particularly complains—that very part shows the accuracy of Hasselquist. For instance, Hasselquist, after describing the hairs round the edge of the top of the horns, says, 'Apex cornuum in medio horum pilorum obtusus, nudus' (the apex of the horns in the midst of these hairs is obtuse and naked), thus conveying in a few words the real condition of that part of the structure, and showing the acuteness of his observation. But Buffon had no very great love for Linnæus or his pupils; and Sparrman, in his 'Voyage to the Cape,' attacks the French zoologist in no measured terms, exposing with a rough hand his blunders, and appearing resolved to appease the manes of the meritorious Hasselquist for the insult of the count. Buffon's figure is bad, particularly about the horns, and the mane is too long.

The description of M. Allamand, in his supplement to Buffon's account, taken from the specimen sent by M. Tulbagh, governor of the Cape of Good Hope, and preserved at Leyden, well supplies the defects of Buffon, and he gives accurate measurements. We would particularly call attention to the following observations of M. Allamand:—'Although the horns are solid like those of a deer, I doubt whether they are shed like them: they seem to be an excrescence of the os frontis, like the bone which serves for the core of the hollow horns of oxen and of goats, and it is scarcely possible that they can be detached. If my doubt is well founded the Giraffe will be a peculiar genus (un genre particulier) differing from all those under which are comprehended the animals who shed their horns and those whose horns are hollow but permanent.' Again, he says, 'the adult Giraffes have in the middle of their forehead a tubercle which seems to be the commencement of a third horn: this tubercle does not appear upon the head of our specimen, which probably was as yet too young to show it.' M. Allamand also remarks that in this young specimen the height of the posterior legs equals that of the anterior, and that the mane is three inches in length.

In *Phil. Trans.* (vol. lx., p. 27) is the following 'Letter on a Camelopardalis found about the Cape of Good Hope, from Captain Carteret to Matthew Maty, M.D., sec. R.S.,' dated on board of the Swallow, Deptford, 20th April, 1769—read January 25, 1770.—

'Sir,—Inclosed I have sent you the drawing of a Camelopardalis (Tab. 1), as it was taken off, from life, of one near the Cape of Good Hope. I shall not attempt here to give you any particular description of this scarce and curious animal, as it is much better known to you than it can be to me; but from its scarcity, as I believe none have been seen in Europe since Julius Cæsar's time (when I think there were two of them at Rome), I imagine its drawing and a more certain knowledge of its reality will not be disagreeable to you. As the existence of this fine animal has been doubted by many, if you think it may afford any pleasure to the curious, you will make what use of it you please.

'The present governor of the Cape of Good Hope has sent out parties of men on inland discoveries, some of which have been absent from eighteen months to two years, in which traverse they have discovered many curiosities, which it is to be hoped they will in convenient time communicate to the world. One of these parties crossed many mountains and plains, in one of which they found two of these creatures, but they only caught the young one, of which the inclosed is the drawing, as it was taken off by them; they endeavoured to bring it alive to the Cape town, but unfortunately it died. They took off his skin, which they brought as a confirmation of the truth, and it has been sent to Holland. These particulars, as well as the drawing, I got from Mr. Barrawke, first secretary to the Dutch Company at that place, in the presence of the governor. I am, sir, your most humble most obedient servant,

Ph. Carteret.'

To this is appended the following note:—

'The animal described in this letter is now in the cabinet of Natural History at Leyden, where I have seen it this year. M. Maty.'

Then comes the figure, and opposite to it, p. 29—

'Dimensions of a male Camelopardalis, killed in a journey made in the year 1761, through the country of a tribe of Hottentots, called the Mamacquas:—

	Ft.	In.
'Length of the head	1	8
Height of the fore-leg, from the lower to the higher part	10	0
From the upper part of the fore-leg to the top of the head	7	0
From the upper part of the fore-leg to the upper part of the hind-leg	5	6
From upper part of the hind-leg to the tail	1	6
Height of the hind-leg from the upper to the lower part	8	5'

Pennant, in the first edition (1771) of his 'Synopsis of Quadrupeds,' shows to what extent the doubts of the animal's existence had been carried; for, after adverting to its locality, 'the forests of Æthiopia and other interior parts of Africa,' and its habits, he proceeds—'I saw the skin of a young one at Leyden well stuffed and preserved; otherwise

I might possibly have entertained doubts in respect to the existence of so extraordinary a quadruped. Belon's figure is very good.' The specimen here alluded to was most probably that mentioned by M. Allamand and in Captain Carteret's letter.

The travels of Dr. Sparrman occupied a period from the year 1772 to 1776. He gives Allamand's description, and adds the following: 'This animal, when it goes fast, does not limp, as some have imagined, but sometimes paces and sometimes gallops. Every time it lifts up its fore-feet it throws its neck back, which on other occasions it holds erect; notwithstanding this, it is by no means slow when pursued, as M. de Buffon supposes it to be, but, on the contrary, it requires a fleet horse to hunt it. In eating the grass from off the ground it sometimes bends one of its knees, as horses do; and, in plucking leaves and small branches from high trees it brings its fore-feet about a foot and a half nearer than usual to the hind feet. A camelopardalis which Major Gordon wounded in the leg, so that it could not raise itself from the ground, nevertheless did not show the least signs of anger or resentment; but, when its throat was cut, spurned against the ground with a force far beyond that of any other animal. The viscera resembled those of gazels, but this animal had no porus ceriferus. The flesh of the young ones is very good eating, but sometimes has a strong flavour of a certain shrub, which is supposed to be a species of *mimosa*. The Hottentots are particularly fond of the marrow, and chiefly for the sake of this hunt the beast, and kill it with their poisoned arrows. Of the skin they make vessels, in which they keep water and other liquors.'

Le Vaillant did not meet with the Giraffe till his second journey into the interior of Africa from the Cape during the years 1783-84-85. But at the end of the 2nd volume of his first journey, which commenced in 1780, he gives figures of a male and female Giraffe, and a compendium of his observations, remarking that it is a kind of anticipation which is owing in some measure to solicitations which he ought to consider as commands. As Le Vaillant appears to be the first well-informed zoologist of modern times who saw the animal in a state of nature, and as he hunted it and brought it down with his own fusil, his account is worthy of particular attention.

'If,' says Le Vaillant, 'among the known quadrupeds precedency be allowed to height, the giraffe without doubt must hold the first rank. A male which I have in my collection, and of which a figure is given in the 8th plate, measured, after I killed it, 16 feet 4 inches, from the hoof to the extremity of its horns. I use this expression in order to be understood; for the giraffe has no real horns, but between its ears, at the upper extremity of the head, arise, in a perpendicular and parallel direction, two excrescences from the cranium, which without any joint stretch to the height of eight or nine inches, terminating in a convex knob, and are surrounded by a row of strong straight hair, which overtops them by several lines. The female is generally lower than the male. That represented in the following plate was only 13 feet 6 inches in height; and her incisive teeth, which were almost all worn away, incontestably proved that she had attained to her full growth. In consequence of the number of these animals which I killed and had an opportunity of seeing, I may establish as a certain rule that the males are generally 15 or 16 feet in height, and the females from 13 to 14 feet. Whoever should judge of the thickness of these animals from the above dimensions would be greatly deceived. The eye indeed that is accustomed to the long, full figures of Europe, finds no proportion between a height of 16 feet and a length of seven, taken from the tail to the breast. Another deformity, if it may be called so, makes us contrast the parts before with those behind. The former have a considerable thickness towards the shoulders, but the latter are so thin and meagre that they do not seem formed the one for the other. Naturalists and travellers who speak of the giraffe all agree in making the hind legs only half the length of those before; but did those who assert so really see the animal, or, if they saw it, did they consider it attentively? An Italian author, who certainly never saw it, caused a figure of it to be engraved at Venice, in a work, entitled 'Descrizioni degli Animali,' 1771. This figure is formed exactly from the descriptions which had then been published of the animal; but this exactness renders it so ridiculous, that we must consider it, on the part of the Italian author, as a severe criticism on all the accounts which had appeared, and which have been so often repeated.' Le Vaillant then goes on to remark that of all the old authors who have treated of this animal Gillius is the most accurate, who expressly says that the giraffe has its four legs of the same length; but that the fore-thighs are so long in comparison of those behind that the back of the animal appears inclined like the roof of a house. 'If,' says Le Vaillant, 'by the fore-thighs Gillius means the omoplate, or shoulder-blade, his assertion is just, and I perfectly agree with him.' In a note it is added, that among the moderns the most exact engraving is without doubt that which was executed under the inspection of Dr. Allaman, from drawings furnished by Colonel Gordon. After observing that the account of Heliodorus is far from being correct, Le Vaillant continues thus:—'The horns, forming part of the cranium, as I have already said, can never fall off. They are not solid like those of the stag, nor composed of any substance analogous to those of the ox; much less do they consist of hair united, as Buffon supposes. They are simply of a bony calcareous substance, divided by a multitude of small pores like all bones, and are covered throughout their whole length with short coarse hair, which has no resemblance to the soft down that covers the young horns of roebucks or stags.' The French traveller then notices the defective figures of Buffon and Vosmaer, observing that the defects disgrace and render of no utility to science such false representations, which people very improperly confide in on account of the reputation of the authors who publish them. He states that the giraffes, both male and female, are spotted in the same manner; and that, without paying attention to the inequality of size, they may easily be distinguished from each other, even at a distance. The male, on a greyish-white ground, has large spots of a dark-brown colour, almost approaching to black; and the female, on a like ground, has spots of a tawny colour, which renders them less striking. The young males are at first of the colour of their mother, but in proportion as they advance in age and size they become browner.

We must here interrupt Le Vaillant's interesting account to remark that, as yet, no difference of any consequence can be seen in the colour of the spots of the male and female giraffes in the gardens of the Zoological Society of London; they are tawny in both.

To return to Le Vaillant: he says that these quadrupeds feed upon the leaves of trees, and particularly on those of a mimosa peculiar to the canton which they inhabit. Meadow-grass also forms part of their aliment; but they are not under the necessity of kneeling down to browze or to drink, as some have improperly believed. They often lie down to ruminate or to sleep, which causes a considerable callosity on the sternum, and makes their knees to be covered with a hard skin. 'Had nature,' says our author in conclusion, 'endowed the giraffe with an irascible disposition, it certainly would have had cause to complain; for the means with which it is provided either for attack or defence are very trifling. It is indeed a peaceful and timid animal; it shuns danger, and flies from it, trotting along very fast: a good horse can with difficulty overtake it. It is said that it has not strength to defend itself; but I know, beyond a doubt, that by its kicking it often tires out, discourages, and even beats off the lion. Except upon one occasion I never saw it make use of its horns: they may be considered of no utility, were it possible to doubt the wisdom and precautions employed by nature, whose motives we are not always able to comprehend.'

Gmelin, in his 13th edition of the 'Systema Naturæ' (1789), elevates the giraffe to a genus under the name of *Camelopardalis*, with the following generic character:—Horns very simple, covered with skin (simplicissima pelle tecta), terminated by a fasciculus of black hairs. Lower incisor teeth (dentes primores inferiores) eight, spatulate, the last deeply bilobated externally. He gives one species, *Camelopardalis Giraffa*, and says that it inhabits Sennaar, between Upper Egypt and Ethiopia, where it has been now seen; that it is rare in Abyssinia, and most rare in more Southern Africa; that its haunts are leafy woods and that it is wild, timid, very swift (celerrima), and elegant; that it reposes prone like a camel; that it feeds on grass by divaricating the fore-legs, but that its principal food consists of the leaves of trees.

In the third edition of Pennant (1793), several additions are made to the description of the giraffe, but he does not notice Le Vaillant, though the first part of the travels of

the latter, containing the account which we have already given, was published before the issue of the edition and before it left Pennant's hands; for the preface with his signature is dated 'Downing, December, 1792.' He alludes to the measurement in the *Journal Historique*, and, quoting Paterson, describes the horns as one foot and half an inch long, ending abrupt, and with a tuft of hair issuing from the summit, adding that they are not deciduous.
